This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

ON PERSISTENT FLATNESS ON PERCUSSION OVER THE LIVER AS PROOF THAT DIFFUSE PERITONITIS IS NOT ASSOCIATED WITH INTESTINAL OR GASTRIC PERFORATION.[1]

BY AUSTIN FLINT, M.D.

AT the annual meeting of the Medical Society of the State of New York, in 1882, I read a paper entitled "On the physical diagnosis of peritonitis, with and without perforation of the alimentary canal." This paper was published in the volume of the *Transactions* of the Society for that year. The chief object of the paper was to call attention to the value of persistent hepatic flatness on percussion in cases of diffuse peritonitis, as constituting proof that perforation of the alimentary canal has not taken place. I did not claim originality in submitting this point in diagnosis. It is true that few, if any, American authors had taken cognizance of it, and I think that reference to it will be found in few, if any, British works on practical medicine. It is, however, noticed by some recent German writers. The portion of my paper which I suppose to have been original, was an account of experiments upon the cadaver, which demonstrated that the injection into the peritoneal cavity of a moderate quantity of air causes the disappearance of the flatness on percussion over the liver, ascertained to have existed prior to the introduction of the air.

It must be apparent, on a little reflection, that the point in diagnosis involved in these experiments is an important one. With reference to prognosis, and in some measure to treatment, it is desirable to know whether or not diffuse peritonitis is associated with perforation. If, therefore, persistent hepatic flatness on percussion be a physical sign which warrants the exclusion of perforation in all, or even in a considerable proportion of cases, the diagnostic point certainly is worthy of consideration. My paper was published in THE MEDICAL NEWS, as well as in the *Transactions* of the New York State Medical Society. I do not recollect to have seen the point in diagnosis noticed in the writings of my brethren at home since the publication of the paper. I may, however, mention that at the meeting of the International Congress last summer, at Copenhagen, Prof. Ewart, of Berlin, well known by his writings on diseases of the digestive system, took occasion to tell me that he had read the paper, and that he was interested in the experiments. I had also an opportunity of presenting the topic at the Medical Section of the Congress, in a discussion upon the treatment of peritonitis by opium, availing myself also of the opportunity of stating the services of Alonzo Clark, in the inauguration of that method of treatment thirty years ago.

My object in the present paper is to cite, and to offer brief comments on a case reported in the article on peritonitis, contained in the second volume, just published, of the *System of Medicine by American Authors*. The chief interest of the case relates to its bearing on the value of persistent flatness on percussion over the liver as a means of excluding perforation. The case, quoted in full, is as follows:

"March 3, 1883, autopsy of Wm. Fletcher, age 59, ironworker. On Friday last, February 23d, he was attacked with pain in the region of the right iliac fossa; it was severe. There was no chill, but little fever, and only slight acceleration of the pulse. His stomach was a good deal disturbed, and the bowels were soon distended with flatus. I saw him on Tuesday following, with James D. Elliott. The bowels were a good deal swollen and very resonant on percussion; pulse 84. His stomach was still greatly disturbed, so that he retained no food, yet there was no green vomit, but much flatulency. The movements in respiration were particularly noticeable, being nearly or quite as much abdominal as in health. There was a short friction sound in inspiration, but an entire absence of the sound produced by peristaltic action. There was no dulness on percussion over the iliac fossa, and no pain on pressure over any part of the abdomen. I was careful in examining the right fossa, for the first pain was there, and it was severe; but there was no physical sign by which the perforation could be ascertained, still my mind dwelt on the probability of perforation, and I expressed my fears to Elliott regarding it. The respiration was of natural frequency. The bowels had not moved for two or three days."

"The next day Flint was added to the consultation. The symptoms had changed but little; the pulse was 102; no pain, no tenderness, no peristaltic action; slight friction at one point only; the abdominal respiration was as marked as before. Frequency of respiration 18; patient sleepy; pupils only slightly contracted. When we were in consultation I again expressed my fear of perforation, but Flint expressed the most decided opinion as to its absence, because there was no dulness to percussion over the liver. I had seen his paper on the intrusion of gas between the ribs and liver in cases of intestinal perforation, and felt as if I were almost reproved for entertaining the thought without physical corroboration."

"Monday, March 1st, the stomach has become more retentive; there was no pain and no tenderness on pressure; pulse 109; no friction sound, no sound of peristaltic action, no dulness on percussion over right iliac fossa, but resonance over the whole abdomen, excepting over the pubes; there the resonance was not clear; over a small space there was dulness, this was ascribed to moderate fulness of the bladder, and, as there had been no difficulty in emptying it, nothing was said of it. The abdominal respiratory movements were the same as before."

"Friday morning at 3 A. M., no marked change had occurred in the symptoms, but from this time onward

[1] Read at a stated meeting of the New York County Medical Association, June 15, 1885.

Digitized by Google

there was a steady sinking of the vital powers. The pulse grew small and frequent, the hands became cool, the breathing more frequent, and without any sudden change or new symptoms, he died early in the morning. At the last visit there was no resonance on percussion over the liver."

"Autopsy, Saturday, March 3d, 2 P. M. The bowels were distended, as they mostly are in peritonitis, but not extraordinarily. There was now pretty free resonance over the liver. The section to open the abdominal cavity was carefully made, with the aim of ascertaining whether there was air or gas in the peritoneal cavity. When a half-inch opening was made through the peritoneum, gas was forced out through it for some seconds with an unmistakable noise. The bowels were not opened by this cut. The bowels exposed, a very thin film of false membrane was found on the middle and upper portions of the intestines, with a fringe of injection where the folds came in contact. But two or three inches above the symphysis pubis, the section opened a collection of pus which extended downward into the pelvis. Somewhere hereabout—neither of us could say exactly where—was found a lump of fecal matter, not indurated, as large as a marrowfat bean, the intestine still unopened. Search was made for the vermiform appendix. At first it was not recognized on account of its remarkable shortness; it was found, however, pointing directly toward the median line of the body, and was short because a part had been separated from the rest by slough. The end of what remained was marked by a border, one-eighth of an inch deep, of a very dark green gangrenous color. We did not attempt to measure the quantity of pus. It was six ounces or more. It was completely bounded and shut in by adhesions."

"At no time during life was there resonance over the liver, but there was at the time of post-mortem examination before the bowels were opened, due perhaps to the fact that at death the relaxation of the muscles allowed the gas to rise higher than it did during life. The unusual median position of the abscess is important in accounting for the absence of dulness, where it is usually found in slough or ulcer of the vermiform appendix."[1]

I infer from the foregoing report that the reporter regarded this case as invalidating the value of persistent flatness on percussion over the liver as a physical sign denoting absence of air or gas within the peritoneal cavity. This seems a fair inference although a decided opinion to that effect is not expressed. There is no other reference to my paper or to this sign in the article on peritonitis. Admitting the correctness of the facts in the case as stated in the report, my interpretation of them differs from that of the reporter.

Here was a case in which a patient was suddenly attacked with severe pain in the right iliac fossa. Four days afterward, when first seen by the reporter of the case, this pain had ceased, the movements of respiration were abdominal, there was no pain on pressure over any part of the abdomen, the pulse was 84, and the respirations of natural frequency. I submit that there was insufficient evidence of acute diffuse peritonitis at that time. On the fifth day I was added to the consultation. The symptoms were unchanged, except that there was some more increase of the frequency of the pulse (102). Flatness on percussion over the liver persisted, and on this fact I based a decided opinion that there was no diffusion of air or gas within the peritoneal cavity. On the sixth day, there was no change in the symptoms, except that there was some further increase in the frequency of the pulse (109), and improvement as regards the disturbance of the stomach. Up to this date the prognosis had been favorable. On the seventh day, at 3 o'clock in the morning, no marked change in the symptoms had taken place, but shortly afterwards the symptoms of collapse were rapidly developed, and death took place within a few hours.

The autopsy showed a circumscribed collection of pus—a peritoneal abscess—around the cæcum, with sloughing away of a portion of the appendix vermiformis, and the appearance of a very recent diffuse peritonitis. The flatness on percussion over the liver had disappeared, and on opening the abdomen gas escaped freely. My interpretation of these facts was, and is, that a few hours before death the gaseous, with perhaps some of the purulent, contents of the peritoneal abscess escaped beyond the boundaries of the abscess, and hence the development of diffuse peritonitis; the collapse and death being due to the latter.

At the time of the occurrence of this case, I made a brief memorandum of it in an interleaved copy of my treatise on the *Principles and Practice of Medicine*, with a view to the utilization of the case in a future edition of the work, as an illustration of the usefulness of persistent hepatic flatness in deciding against the presence of gas in the peritoneal cavity. My memorandum is as follows:

"February 28th, visited Mr. P. with Drs. Elliott and Clark. Peritonitis had existed for three or four days. At this time hepatic flatness was marked. He was apparently doing well under full opiate treatment, after March 2d, at 3 o'clock A.M. At that hour he was seen by Dr. Elliott, and there was no change for the worse. At 6 o'clock A.M., he was in collapse, and died during the forenoon. Before the autopsy, percussion showed absence of hepatic flatness, and great abdominal distention, a portion of the vermiform appendix had sloughed away, leaving an opening. There was a local collection of purulent matter near the appendix, but elsewhere the appearances did not denote intense inflammation. Conclusion: The patient was progressing favorably when sloughing of the appendix caused an opening, and death was by shock. The large intestine was collapsed; the small intestine much distended with gas. March 4, 1883."

This case is of interest in another point of view than with regard to the validity of persistent flatness over the liver, as proof against the presence of air in the peritoneal cavity, namely, the opportunity which it offered for surgical interference. It is often easier to look back upon the history of a case with the light afforded by an autopsy, and to consider what might have been done, than to decide upon a bold measure of treatment during the progress of the case. Here was a circumscribed peritoneal abscess as shown by the post-mortem examination. Had the purulent collection been demonstrated by exploration and removed by aspiration, it is possible that recovery might have taken place; or, again, the question may be raised, whether a free incision into the abscess might not have been advisable, and the perforated appendix ligated. As bearing on these

[1] System of Med. by American Authors, vol. ii. p. 1157.

Digitized by Google

points of inquiry, a case reported by Dr. Z. B. Adams, of Framingham, Massachusetts, in the *Boston Medical and Surgical Journal*, November 20, 1884, is of much interest. In this case a peritoneal abscess was opened, a quart of pus escaping, and subsequent injections of carbolized water resorted to, complete recovery taking place. I may also refer to a paper by Leyden, in the *Verhandlungen des Vereins für innere Medicin zu Berlin*, in which this writer expresses the opinion that suppurative peritonitis should be treated after the plan in use in empyema, and cases are cited in support of this opinion.[1]

I must content myself with this bare allusion to the surgical treatment in cases of peritonitis, a subject which offers a wide scope for consideration and discussion.

TWO CASES OF FRIEDREICH'S DISEASE.[2]

BY WHARTON SINKLER, M.D.,
PHYSICIAN TO THE INFIRMARY FOR NERVOUS DISEASES, PHILADELPHIA.

THE two cases which I shall relate resemble in many respects the so-called Friedreich's disease, but in both is wanting one characteristic feature, namely, the hereditary or congenital history. In all of the cases reported by Friedreich there were two or more instances of the disease in the families to which the patients belonged. Gowers reported five cases of this form of ataxia in a family of nine children.

The cases of Friedreich and Gowers are not, strictly speaking, hereditary, for neither the parents nor any of the ancestors, as far as known, were ataxic. Cases are on record, however, which are hereditary; for instance, those of Carré, reported by Brousse, in which of twelve children seven were ataxic; the mother was ataxic, and her brothers and sisters, eight in number, as well as one cousin, were also affected with ataxia.

As far as I can discover, none of the progenitors of either of the cases which I report are ataxic. The brothers and sisters also appear to be healthy in all respects. I am indebted to the kindness of Dr. Weir Mitchell for the opportunity of reporting the following case:

CASE I.—C. G., æt. 18 years, male, consulted Dr. Mitchell in May, 1884. The following notes were taken by Dr. Morris J. Lewis: "There is no history of ataxia or of nervous trouble in his family. A paternal uncle and two first cousins had phthisis. No consumption in immediate family. Until eleven years of age the patient was considered perfectly healthy. He then had scarlatina, but recovered perfectly and had no kidney complications.

"An awkwardness, which had been previously noticed, but which had been thought to be habit, now became more marked, but it was not until the age of fifteen that he became aware of it himself. When thirteen he had an abscess of the lower jaw, and after this his disability increased more rapidly. His difficulty in walking is described as being 'a winding shuffling gait.' This was the first symptom noticed, but almost immediately after this he was observed to be awkward in the management of his arms and hands, and to have some hesitation in speech. The exact time of the appearance of each symptom cannot be fixed more accurately. Previous to this trouble he was considered in school to be a fluent speaker, and to be quick and bright, but since then he 'thinks slowly' and his speech is slow and awkward.

"Before 1876 he had occasional asthmatic attacks, which were relieved by smoking stramonium. In 1883 he had an attack of 'intermittent fever' and was in bed for three months (the rest in bed was ordered for his nervous trouble and not for his malaria). Since then he has never walked without help. For five years there has been difficulty in walking in the dark.

"*Present condition.*—He cannot walk without help, and then only with great difficulty and fatigue. His gait is exactly like that of an ataxic. He has great difficulty in writing or doing anything with his hands. His writing, however, has always been bad and awkwardly performed. He has not and never has had lancinating pains, areas of anæsthesia, or numbness. The knee jerk, cremaster and abdominal reflexes are all absent. He has no trouble of vision, his pupillary reflexes are present, and there is no nystagmus. There are no visceral crises, nor are there any trophic changes.

"Both great toes are the seat of considerable contracture, they are turned upwards towards the dorsum of the feet. There is also some contraction of the plantar fascia.

"He has perfect control over his bowels; there is some difficulty in the commencement of the act of urinating, but not after the flow has begun."

CASE II.—Mary G., æt. 11 years, came to my clinic at the Orthopædic Hospital and Infirmary for Nervous Diseases. She is the oldest of five children. The others are all healthy and have had no diseases of the nervous system. The parents are healthy, and neither they nor any ancestors they know of have had any nervous affections. Mary has had no other illness, except measles, which she had after the present trouble began. About October, 1882, when she was eight years old, her mother noticed that her hands were unsteady, and that she dropped things; then she walked awkwardly, and often stumbled and fell. This awkwardness and incoördination has increased. At no time has there been pain of any kind in the limbs or body. There has been no disorder of the bladder or rectum, and there have been no attacks of gastric disturbance. Her general health has been good and she has continued at school.

Present condition, May, 1885.—The patient is well nourished, and the limbs are full and well developed. While standing, the body sways to and fro, and this increases to a considerable extent when the eyes are closed; in fact, the patient would fall if she were not caught. There is marked antero-posterior curvature of the spine. This is muscular, and not due to caries of the spine. A line let fall from the neck falls clear of the sacrum. The movements of the hands are awkward and badly directed, but she can execute most movements. The patella

[1] Vide Am. Journ. Med. Sciences, page 573, April, 1885.

[2] Read before the American Neurological Society, June 19, 1885.

Digitized by Google

reflex is absent on both sides. Skin reflexes good. Pupillary reflexes good for light and accommodation. The sensation of the skin is undisturbed, and there is no analgesia. The skin of the legs seems thicker than usual, and is closely adherent to the cellular tissue. The muscles of the legs respond normally to the faradic current. The response to galvanism seems to be quantitatively lessened, but so great pain is caused by this current that it is difficult to determine positively the degree of response. There is no affection of speech, and the intelligence is good.

The patient's walk is peculiar, but does not closely resemble that of an ataxic person. It is unsteady and staggering. When her eyes are closed she has difficulty in guiding the fingers to place them on any part. Urine normal. Dr. Charles A. Oliver has kindly made a most thorough and scientific study of the ocular conditions of the case. The following is his report:

O. D. V.$=\frac{6}{6}$. Sn. o.5 D. 8 cm.—63 cm.

O. S. V.$=\frac{6}{6}$. Sn. o.5 D. 8 cm.—63 cm.

Conjunctivæ have numerous small phlyctenulæ. Corneæ clear. Pupils round, three millimetres each in horizontal diameter. Irides equally mobile for both light stimulus and accommodative effort. Extraocular motion in all directions; no doubling of images produced. Upon extreme convergence and extreme divergence, both conjoined and separately, a horizontal nystagmus develops itself—this being of a peculiar character—three or four movements, each one lessening; the primary excursion extending over two or three millimetres, at about the rate of two to three per second, until fixation establishes itself. When binocular fixing is attempted for an object at about thirty centimetres distance on the median line, the horizontal nystagmic motion occurs, the eyes being first *out* under cover. In Von Gräfe's test (dot and line), the patient denies either persistent homonymous or crossed images; in a few moment's time the false image swinging upon the vertical line occupied by the true dot.

Ophthalmoscopic Examination without the Use of a Mydriatic.—O. D. Media clear. Disk round, about six diameters in apparent size. Decidedly gray in its deeper layers and rather over capillary in its superficial substance. Retinal arteries and veins normal in comparative size, color, and area of current. Scleral ring plainly seen in and out. Heavy black choroidal ring to the nasal side of the nerve. To the temporal side of the disk there is a black crescent of pigment with a narrow area of disturbed choroid beyond. Some retinal lymph reflexes specially along the main stems of the retinal arteries and veins. Macular region healthy in appearance. Fine retinal striation extending around the entire disk and far out into the retina, but nowhere hiding the outline of the nerve entrance. No splotches or hemorrhages can be seen throughout the entire fundus. H. with Ah. about 1 D. and o.5 D.

O. S. Media clear. Disk vertical oval, six by seven diameters in apparent magnitude. Much grayer in its deeper layers than in the other eye, with about the same superficial capillarity. Edges of disk everywhere visible, yet slightly veiled by a fine striation of retinal fibres. Scleral ring visible all around the nerve, but rather more plainly seen to the temporal and nasal sides. To the outside of the disk there is a narrow black rim of pigment, whilst to the inside there is a faint trace of a choroidal ring. Retinal vessels normal in relation to their average size, color, and calibre. No visible splotches or hemorrhages. Macular region appears healthy. Numerous lymph reflexes generally situated along the vascular distribution of the retina. H. with As. about 1 D. to 1.5 D.

Color Perception at Five Metres.

	O. D.	O. S.
Red.	3 mm.	3 mm.
Green	4 mm. = blue. 8 mm. = green.	9 mm.
Blue	7 mm. = green. 13 mm. = blue.	7 mm. = green. 13 mm. = blue.
Yellow	10 mm. = yellow.	7 mm. = yellow.

(This done by color-sense measure.)

Résumé and Conclusion.

1. Acuteness of Direct Vision for Form.—Normal in each eye. This shows that the brunt of the disease has fallen but slightly upon those fibres of the optic nerves which are distributed to the macular regions of the ocular retinæ; this, no doubt, being dependent upon their greater physical strength and their greater resisting powers to pathological change.

2. Direct Vision for Color.—The first test was made by placing the patient at five metres distance from a mechanical contrivance in which definite areas of certain known colors can be exposed to each eye separately.[1] Four colors were tried (red, green, blue, and yellow). The comparative results with the two eyes were about the same, although it must be remembered that the left eye, which was the second tested, had the advantage of previous knowledge, even though an attempt was made to exclude this error by telling the patient that a new card of colors would be used; the average results being what has been before determined to be normal.[2] The second test, which consisted in a modification of Holmgren's method of wool selection, in first having all of the skeins thrown upon a dead black surface and then adding to his three tests a blue and a yellow selection (which the present writer has elsewhere designated as "confirmation tests"),[3] showed the earliest recognizable state of subnormal color-perception in which the condition is manifested "by an incapability to respond to very weak intensities of the entire number of pure natural colors which constitute the normal average power of the human visual apparatus; this expression of inability being more pronounced with those beams of natural colored light which are productive of "green."[4]

These two series of results show that the atrophic change in the optic nerve fibres distributed to the macular regions of the ocular retinæ is in its incipiency, this being evinced by the slight recognizable defect in color-perception. The reason that the fault is more manifest amongst the "greens," is that such natural colors are the most difficult for normal perception.

3. Visual Fields.—These were carefully taken with a one-centimetre square each of white, yellow, blue, and red, at thirty centimetres distance, for each eye separately. No scotomata, excepting the normal ones for the disk areas (which in themselves were not abnormally enlarged), could be found. Each field for white was uniformly contracted in all meridians to about twenty to thirty degrees. The fields for yellow were limited to spaces bounded by twenty degrees. Blue area obtained from the right eye occupied an irregular space bordered by a circle equivalent to about fifteen degrees, whilst the same color in the left eye was seen in a space bounded by only five to eight degrees. The red field in

Digitized by Google

the right eye enclosed a space of about five degrees in all directions, whilst the same color in the other eye gave an area of about two to three degrees.

These unequal and great contractions of the visual fields in the two eyes are important and show two absolute conditions: first, that the degenerative process has invaded the two optic nerves to different degrees; and, second, that although the pathological disturbance has most probably involved each optic nerve uniformly in transverse section, yet upon account of the lower functional ability of the circummacular distribution in the ocular retinæ (dependent upon a lower grade of physical structure), visual expression of structural degeneration has been greater amongst the peripherally placed fibres, thus producing concentric contraction of the visual fields.

4. Motions of Iris.—Want of Argyll-Robertson phenomenon. The entire absence of "reflex-iridoplegia" in this case is interesting. The facts that the macular fibrils of the afferent path to the central nucleus are in excellent working condition and the efferent tract has been but slightly affected, combined with the assumption that the special centre (*i. e.*, the cerebral area just behind the space set apart for the centre governing the act of accommodation) has as yet escaped any detrimental disturbance, give very good answer for the reason of the non-appearance of this symptom.

5. *Extra-ocular Motion.*—Horizontal nystagmus in each eye. It is undoubtedly a *paretic* condition.

Conclusion.—Careful analyses of these various eye symptoms have drawn me to the conclusion that in this case we have to deal with ocular conditions which are related to some peculiar form of locomotor ataxia.

These cases, with certain exceptions, are decidedly like locomotor ataxia, but the ordinary form of this disease is very unusual in children. Hammond says it is met with between thirty and forty-five years of age. Eulenberg[1] in 149 cases found but one instance (female) under ten years of age. Erb,[2] out of eighty-six cases of his own, met with three instances between eleven and twenty years.

In a "critical digest of the so-called hereditary ataxia, first described by Freidreich," by Dr. J. A. Ormerod,[3] the writer has collected forty cases of this affection. I am indebted to this paper for much valuable information on the subject.

This author remarks of the disease that its most striking feature is its tendency to attack many members of the same family. Next, that it attacks in early life. "Friedreich stated that it coincided with commencing or developing puberty, the dates of his cases varying from æt. 13 to æt. 18, but other authorities have observed it still earlier. Thus of Rutimeyer's cases it began above the age of four years (one child indeed had never been able to walk straight); and in two of Hammond's cases it began at a similarly early age." The first symptom is almost invariably ataxia of the legs, then it gradually extends upwards, affecting the arms, head, and, finally, the speech. Nystagmus also occurs late in the disease. The absence of sensory symptoms is of great interest. In typical cases of locomotor ataxia the pains, as is well known, are a prominent symptom, especially in the early stages, and later on sensory disturbances: anæsthesia, paræsthesia, etc., frequently are present. In Friedreich's disease "pain is conspicuous by its absence." "Romberg's symptom"—*i. e.*, inability to stand with the eyes shut and the feet together, is not always present, but the knee phenomenon is always absent, spinal curvature is often present. Ormerod says a combination of lateral and angular curvature is frequent, but that lateral alone is more frequent than angular curvature alone. It is said to be a very early symptom. In my patient, Case II., there is marked lordosis. Indeed, so marked was this condition that on first seeing the case and observing a very stout condition of the calves of the legs in connection with the spinal curvature I suspected it might be a case of pseudo-hypertrophic paralysis.

Paralysis and atrophy come on later in the disease. Many of the cases recorded were under observation for a great number of years. One of Friedreich's was seen by him for thirty-one, and another for twenty-five years. As the disease progresses, the patient becomes utterly helpless from the degree of paralysis.

Post-mortem examinations were made in seven of the cases collected by Ormerod. The following is a *résumé* of the changes found:

"In several cases the cord and medulla were small in size, and this is certainly a fact of interest when we consider the hereditary character of the disease, for a cord congenitally imperfect may be the more prone to degeneration, and to degenerate at an early age. Advanced posterior spinal sclerosis was found in every post-mortem. The changes in the medulla were slight and apparently secondary to the spinal. So in Friedreich's opinion were those which he found in the nerve trunks; while in the cerebrum and cerebellum, no trace of chronic disease was found."

Ormerod says "he cannot adopt Hammond's suggestion that the lesion is primarily situated in the medulla or cerebellum. He thinks that as the sclerosis involves the entire length of the posterior columns, and appears to spread upwards much as in ordinary ataxia, we should class it as a systematic tract lesion, and not as a part of a disseminated sclerosis."

Hammond[1] believes that Friedreich's cases are not forms of ataxia at all, but are instances of disease of the medulla or cerebellum extending secondarily to the cord. Erb, on the other hand, accepts Friedrich's views, stating that "most cases of tabes dorsalis may be grouped under one of two types—*i. e.*, the classic variety of Duchenne, or that described by Friedreich."

In conclusion, we would recall the difference in the two forms of the disease. The typical variety begins with lightning pains, disorders of micturition, transient paralysis (especially oculo motor), absence of pupillary reflex; the Argyll-Robertson symptom; visceral crises; and trophic disturbances in the joints and bones. All of these are absent in the form described by Friedreich, and in this latter variety the spread of the affection to the arms is more rapid, the spinal curvature, the disturbance of

[1] Journal of Mental and Nervous Diseases, 1882.

Digitized by Google

speech, and the nystagmus are peculiar to it. The early age at which it occurs and the family predisposition to the disease make up the other points of difference.

On the other hand, in both types there are the ataxia and incoördination beginning in the lower extremities, the absence of tendon reflexes, and "the Romberg symptom," and some of the eye lesions.

A HEAT CENTRE IN THE CEREBRUM. PRELIMINARY NOTE.

BY ISAAC OTT, M.D.,
OF EASTON, PA.

IT is nearly twenty years ago that Tescheschichin announced, as the result of experiments, that section of the medulla oblongata where it joined the pons caused an increase of temperature. He arrived at the conclusion that physiological experiment and clinical facts point to a moderation-centre in the brain. Some time ago I announced the existence of a heat centre in the vicinity of the corpora striata.[1] This fact has recently been confirmed by Messrs. Aronsohn and Sachs.[2] Lately I have attempted to ascertain more definitely the position of this centre. The experiments were made upon rabbits, not fastened down, in a room the temperature of which was about 75°. The temperature in the rectum was noted, the skull was trephined, and punctures made with a coarse needle through the cerebrum down to its base, and the increment of temperature noted. A rise of temperature usually ensued after injury to various parts of the cerebrum, but it disappeared in a few hours. If, however, it struck a certain point in the anterior inner portion of the optic thalamus, near the corpus striatum, then the rise was from three to four and a half degrees, and remained nearly at this height till next day. The cerebral cortex has not anything to do with it, as I have frequently removed the cortex in different places, and the rise was only transient. There is a possibility that at this point the injury calls vaso-motor influence into activity and causes an increase of temperature. To decide this point, calorimetric experiments are necessary. A few experiments made with D'Arsonval's calorimeter showed an increased heat production. More extended experiments will be necessary to decide this point.

MEDICAL PROGRESS.

DOUBLE OVARIOTOMY(?); CURE.—M. FERRIER reports a case of double ovariotomy remarkable on account of diverse opinions held by eminent diagnosticians as to the nature of the growth previous to operation. The patient, a woman aged forty-three years, had menstruated regularly since the age of fourteen, but at the time of her entrance into the hospital the menstrual flow which hitherto had been profuse, had become scanty. The patient was married at the age of twenty-one, had never borne children nor had a miscarriage. About twelve years previously she experienced pain in the hypogastric and left iliac regions, which was increased by walking, prolonged standing, or by any movement which affected the abdomen. Pressure produced a variable effect. Menstruation was without influence, and dorsal decubitus caused the pain to disappear completely. To the pain already described another was added, having its location in the umbilical region, and somewhat analogous to the pains of menstruation, though not coinciding with them as to time.

This pain lasted from forty-eight hours to five days, and appeared two or three times yearly. The abdomen in the meantime did not become enlarged, and though the pain attracted her attention to the abdomen, the woman was not aware of the existence of a tumor at the time, two years after the initial symptoms. M. Van Petegen was consulted, and recognizing ulceration of the cervix, treated the patient without affording her relief, and having made further examination recognized the tumor. The woman next consulted Prof. Duplay, of Paris, who recognizing the tumor, counselled immediate operation. M. Péan, consulted a few days later, pronounced the tumor to be fibro-cystic, and did not consider operation necessary, at least at once. Four or five years later M. Parise, of Lille, diagnosticated multiple fibro-cystic tumor, and pronounced operation impossible. Soon after, at Strasburg, M. Kœberlé diagnosticated a fibro-cystic tumor, and refused to operate.

The woman finally entered the Hôpital Bichat, January 13, 1884, for the purpose of undergoing operation. Examination showed the belly to be asymmetrical. The circumference at the umbilicus was 39.6 inches, The distance from the umbilicus to the ensiform cartilage was 7.2 inches, and from the os pubis to the umbilicus, 6 inches.

Palpation revealed the presence of two tumors. One was situated in the median line in the hypogastric region, hard, non-fluctuating, and about the size of an apple. The other occupied the whole of the right iliac fossa, and throughout its whole extent, fluctuation was plain.

January 19, puncture was made to the right of the umbilicus at a level with the fluctuating tumor, and a dark-brown fluid full of crystals of cholesterine obtained.

January 22, operation was performed by M. Ferrier, assisted by MM. Périer, J. Championniére and Berger. A median incision was made extending from the umbilicus nearly to the pubes. The peritoneum was found to be vascular and thickened, necessitating the use of the hæmostatic forceps, and containing also a small quantity of ascitic fluid. The right cystic growth was covered by the epiploön which was adherent to it and to the abdominal wall. Below, the subpubic tumors were filled with cysts containing a clear fluid which greatly distended them. The epiploön was gradually detached from the cysts and from the abdominal wall, without much loss of blood. Numerous adhesions existed between the cystic mass and the abdominal wall, and, moreover, on account of the ascites and the long duration of the disease, the adhesions appeared macerated, infiltrated, and of a darkish color. Below and to the right there were extensive adhesions between the cyst and cæcum, which when broken up necessitated numerous ligatures. The right cyst was punctured, and contained about seven pints of a reddish colored liquid

[1] Journal of Nervous and Mental Diseases, vol. xi., April, 1884.
[2] Deutsche medicinische Wochenschrift, December, 1884.

Digitized by Google

full of cholesterine crystals. The abdominal incision was now extended toward the umbilicus. The cyst was found to be connected below with the suprapubic polycystic mass, whose pedicle was ligated with two catgut ligatures. By this procedure the polycystic mass was disengaged and gradually removed from the pelvis, and was thus found to be composed of cysts united to both ovaries, and united below with the uterus. To the left, a second pedicle was discovered, which seemed to correspond to the left ovary. Its section permitted the right uterine pedicle to be reached, and to be tied with a silk ligature. Two vegetative masses were discovered behind the right uterine pedicle and upon the posterior wall of the uterus. These were torn away and removed, and a catgut ligature applied to each of the bleeding points. The toilet of the peritoneum was carefully completed, and the abdominal incision closed with eight deep, and one superficial suture. Strict antiseptic precautions were observed. The operation occupied fifty-five minutes. The patient rallied from the operation, and made a good recovery, and left the hospital, cured, February 23, 1884. Though the tumors appeared to be ovarian in their origin, the subsequent reëstablishment of the menstrual function renders the diagnosis doubtful. —*L' Union Médicale*, June 4, 1885.

NEPHROTOMY.—PROFESSOR FRANZALINI, on May 23, 1885, removed the right kidney of a woman in whom the organ was the seat of multiple foci of tuberculous degeneration. On account of the vast size of the tumor, which is said to have been as large as the head of a seven months' fœtus, and the uncertainty of the diagnosis, the organ was removed by abdominal section. The operation was performed in one hour. The patient is in good condition, and her recovery is confidently expected.—*Gazzetta Medica di Torino*, June 5, 1885.

STIMULATION OF THE VAGUS IN CHLOROFORM NARCOSIS.—DR. EMIL AMRUS has discovered the following interesting facts in reference to stimulation of the vagus in animals anæsthetized by chloroform:

If the peripheral end of the nerve be stimulated with a mild faradic current in an animal so anæsthetized—

1. The duration of the heart's pause is disproportionately long as compared with the intensity of the current.

2. In some instances, in which a relatively weak current is applied, the duration of the heart pause attains a maximum, and, if the strength of the current be intensified or diminished, the duration of the cardiac pause decreases.

3. If the duration of the heart pause is prolonged by continued stimulation through twenty-five or thirty seconds, cessation of respiration also occurs.—*Allgemeine Wien. med. Zeitung*, May 12, 1885.

ALBUMINATE OF MERCURY IN THE TREATMENT OF SYPHILIS.—DR. MAX BOCKHART strongly recommends albuminate of mercury in the treatment of syphilis. After repeated trial he has found it to be efficacious and well borne. Macular exanthems disappear after from three to five injections, and other syphilitic manifestations appear to yield equally well to the remedy. Gummata also disappear with great rapidity by use of the drug, which seems even superior to the peptonate of mercury. Local inflammation never occurs, and, as a result of its hypodermatic use, and though injected into the back, nates, and thighs, induration and abscess never occur. Generally, also, the hypodermatic use of the drug is entirely painless. A solution of albuminate of mercury, of a strength of 1½ per cent., is recommended for general use in injections made daily or every two days. The solution should be kept in a cool place and in colored bottles.—*Monatshefte für Prakt. Dermatologie*, May, 1885.

FRACTURE OF THE OLECRANON.—At a meeting of the Academy of Medicine, of Genoa, held May 4, 1885, Professor Caselli presented a young man who had come to his clinic with an ununited fracture of the olecranon, and on account of which the power of extension in the arm was altogether lost. Professor Caselli removed, by a small incision, the loose fragments of bone and the callus thrown out at the seat of fracture, and sutured the fragments of the bone with a strong metallic wire. Having thus approximated the fragments, he twisted the two ends of the wire, made an incision in the periosteum, and slightly excavated the lower fragment beneath the elevated periosteum, and into the small cavity thus formed, introduced the twisted ends of the suture, after which he replaced the periosteum. Reunion took place by first intention, and in eighteen days the patient was completely cured. The articulation at the elbow was restored to a normal condition, and all movements of the arm are naturally performed. The wire suture remains encysted and causes no discomfort or unfavorable symptoms.—*Gazzetta degli Ospitali*, May 24, 1885.

PULMONARY CONGESTION AND ITS PATHOGENY.—DR. L. QUEGRAT, in an exhaustive study of pulmonary congestion, distinguishes two forms of the pathological conditions—the idiopathic and secondary.

The idiopathic form occurs: 1. As a result of pneumonia. 2. As a result of pleurisy.

Secondary congestive conditions may be (*a*) pulmonary, (*b*) pleural, (*c*) cardiac, (*d*) neuropathic, (*e*) diathesic, (*f*) infectious, (*g*) dyscrasic, (*h*) dependent on the existence of a vacuum.

M. Quegrat considers the pathogeny of pulmonary congestion to be very variable, and but little understood. Thus, in secondary congestion, the condition is at one time caused by an impediment to the return circulation, a mitral insufficiency, for example, which causes the gradual engorgement of the lungs. At other times it is not the impediment offered to the return, but a too abundant afflux of the blood, arising from a local irritation, which causes the congestion. This condition is frequently seen in the region of tuberculous foci.

In a third category may be grouped cases of congestion originating from functional defect of the pulmonary vasomotors, as is seen in the unilateral congestion consecutive to cerebral hemorrhage, and located on the paralyzed side; and also in those reflex congestions consecutive to attacks of bilious colic, or to strangulated hernia. The condition under consideration is thus plainly seen to be due to:

1. Congestion due to obstruction to the circulation of the blood.

2. Congestion due to local irritation.

3. Neuropathic congestion.

Digitized by Google

It is evident, however, that, though these three groups only are at present actually established, in many instances the pathological process is undiscovered. Thus, in rheumatism and arthritis, the causes which produce congestion and the rôles assumed by the nervous system, the fluid of the body, or infectious agents, are questions which are still unsolved.

As to the condition of the so-called idiopathic congestion, sometimes attributed to cold, or considered the manifestation of a catarrhal condition, or as being a congestive fever of the lungs, nothing positive is known. —*Revue de Médécine*, January 10, 1885.

THE INFLUENCE OF SYPHILIS UPON INFANTILE MORTALITY.—At a meeting of the French Academy of Medicine, held March 4, 1885, DR. ALFRED FOURNIER concluded an address upon the reduced increase of the population of France, with the following observations;

1. Syphilis constitutes an active and powerful cause of infantile mortality; the average deaths due to this cause may be estimated at 68 per 100, of children descended from parents suffering with the disease.

2. The remedies by which this special cause of infant mortality may be diminished are of two classes: 1. Methodical and sufficiently prolonged medical treatment, and prohibition of premature union of parties suffering from syphilis. 2. Measures relating to public hygiene (the general prophylaxis of syphilis).

The first are in the hands of the physician, and by using them rigorously the mortality due to infantile syphilis may be much decreased. Measures of the second order, Dr. Fournier held, are in the hands of the health committees and general government, and these where their resources are inefficient should be improved.—*Annales de Dermatologie et de Syphiligraphie*, May 25, 1885.

TREATMENT OF DIPHTHERIA.—DR. LUNIN, in *Wratsch*, 1885, Nos. 2-4, gives a *résumé* of some of the methods commonly approved in the treatment of diphtheria:

1. Treatment with corrosive sublimate. The mucous membrane of the fauces is painted with a 1 per cent. solution and a gargle of a 0.02 per cent. solution is used. But as the latter procedure is too precarious in children, the mouth and throat should be hourly washed with the solution, with the aid of the Rauchfuss spatula, so that it may be certain that the application comes in contact with the entire posterior walls of the throat.

2. Treatment with the liquor ferri sesquichloridi. This remedy may be administered in doses varying with the age of the patient. From one drop every two hours to two drops every half hour, and in daily doses of from 15 to 120 grains. In addition, the mouth and fauces should be hourly cleansed with a 3 per cent. solution of boric acid.

3. Treatment with quinine. This remedy may be used, according to Serpert's prescription, in a strength as follows:

℞.—Quiniæ	gr. lxxv.
Aquæ,	
Alcoholis	āā f℥iss.

The mucous membrane of the throat and palate to be painted every two hours. In addition, the throat should be gargled hourly with a solution of quinine as below:

℞.—Quiniæ	1 part.
Water	500 parts.
Alcohol	50 parts.

4. Treatment with resorcin. Andeer recommends in mild cases of the disease the simple cauterization of the parts with resorcin crystals, or with a concentrated vaselin and resorcin ointment. In moderately serious cases, repetition of the above treatment is recommended, while in severe cases the local and internal use of the drug is recommended.

Cauterization is to be performed by the physician personally; for painting the throat a ten per cent. solution is recommended, and a one per cent. solution should be used for washing the parts; applied at first every two hours and afterwards every hour. The remedy thus far has not been administered internally, though in frequent painting of the throat it is certainly swallowed in greater or less quantity.

5. Treatment with bromine according to the prescription of Von Hiller, who recommends the following formula:

℞.—Bromine, pure,	
Potass. brom. . . .	āā gr. 7½–15.
Aquæ	f℥vj.

With which solution the throat should be washed every two or three hours. Contemporaneously inhalation of a 0.2 to 0.4 per cent. solution of bromine should be practised every half hour or hour for a period of five minutes.

6. Turpentine may be used as recommended by Von Bosse. The patient should twice daily receive a teaspoonful or an hourly dose of ten drops of the drug. In addition, the throat should be washed with a three per cent. solution of borax. If vomiting or diarrhœa ensue, the administration of turpentine should be discontinued.

Following these several methods of treatment, tables are appended, showing the apparent success or failure of each remedy.— *Centralblatt für klin. Med.*, May 2, 1885.

THE EMPLOYMENT OF CURARE IN THE TREATMENT OF EPILEPSY.—DRS. BOURNEVILLE and P. BRICON, in a therapeutic study on the use of curare in epilepsy, based upon the clinical observations of thirty-three cases of the disease in which the drug was employed, have reached the following conclusions:

The results attained are entirely different from those recorded by some authors. Certainly, in twenty-one patients affected with various forms of epilepsy, some adults, and some children, submitted to subcutaneous injections of curare during three, six, and even a greater number of months, but a single case was found in which noticeable benefit was received from the treatment. One other was slightly benefited. In a third, though the number of the attacks was not diminished, their violence was abated, a common result in the treatment of epilepsy. In summing up the results obtained the writers find that they are but little encouraging, and consider that curare should be dropped from the list of drugs worthy of trial in the treatment of epilepsy.—*Archives de Neurologie*, May, 1885.

PHILADELPHIA.

SATURDAY, JULY 4, 1885.

THE INTERNATIONAL MEDICAL CONGRESS

THE new Committee of Organization of the International Medical Congress, met in Chicago last week and the result of its work is greatly to be regretted. The original committee, appointed for that purpose in 1884, proceeded to organize for the International Medical Congress in 1887, in accordance with the rules and customs of previous Congresses. Upon its plan the medical profession of the United States was to be represented as a national body, including all regularly organized medical societies, general or special. The American Medical Association, however, at its late meeting in New Orleans, rejected this arrangement, legislated out of existence the thirty-four members added by the authority given the original committee at the time of its appointment, and added thirty-eight new members to the original committee of eight, in order to put the Congress exclusively under the charge of the Association, with the States and Territories as the unit of representation. The new committee seems to have carried out its instructions pretty thoroughly, although there are still perhaps some districts not sufficiently represented in the appointments made.

It was decided that the American members of the Congress must be members of the American Medical Association, or of societies affiliated with it, on the usual basis of representation of one to ten; in other words, the Congress is to be a meeting of the American Medical Association with a rather larger number than usual of invited guests.

In his remarks before the Committee, Dr. Billings gave the views of the original Committee as follows:

"The invitation was purposely worded as coming from the Medical Profession of the United States, and not from the Association only, in order that all regular physicians in the country, and in particular the various important societies devoted to special branches of medicine, such as the Gynæcological, Ophthalmological, Laryngological, etc., and also the societies in our large cities which are specially devoted to scientific work, such as the Academy of Medicine of New York, the College of Physicians of Philadelphia, etc., should feel that they were included and must share the responsibility of providing a proper reception for the Congress.

"The Congress is a purely scientific body, taking no cognizance of questions of Medical Ethics or police. It accepted the invitation on the supposition that its rule in this respect would not be interfered with, and that those who would come to us in 1887, would meet our various eminent specialists whom they know either personally or by reputation. To make this impossible, as the newly organized Committee proposes to do, is a discourtesy to the Congress.

"So long as the Old Code men in New York meet the so-called New Code men as freely in consultations and in scientific societies as they now do, there is no sufficient reason for refusing to meet them in a purely scientific body like the International Medical Congress."

This remonstrance had not the least effect in modifying the determination of the Committee.

It seems clear that the meeting in 1887 is to be an International Congress in name only and that it is really to be a very large meeting of the American Medical Association, and that the vastly larger body of the medical profession of the United States is to be excluded. What the result will be it is premature as yet to conjecture; but we fear that, under the circumstances, a number of distinguished men, both at home and abroad, whom it was hoped would be present and take part in the work, will not attend.

The management of the matter has passed into the hands of a very different set of men from those who had charge of it at the outset, and the question whether any of the original Committee of eight, or of those who were added to them to form the enlarged Committee which did the work which the new Committee have just condemned and set aside, should consent to accept office under the new *régime*, demands serious consideration. From present appearances it looks as if there would be but little, if any, difference of opinion upon this point.

As we go to press we learn that the dissatisfaction with the work of the new committee is so great that the members of the medical profession of Philadelphia who were concerned in the organization of the Congress, have held a meeting and have unanimously decided to decline to hold office under the new

Digitized by Google

organization. As will be seen by reference to the resolutions passed, this list includes the names of the Chairmen of the Sections of Medicine, Surgery, Anatomy, and Therapeutics; and of the new Secretary General. With the probability of similar action being taken elsewhere, the present outlook is not encouraging.

We are also informed that Drs. Billings, Brown, Johnston, and Hays, of the original committee of seven, have resigned from the enlarged Committee.

INDIRECT FRACTURES OF THE CRANIUM.

THE history of fractures of the cranium occurring at a point some distance from that which has received a blow is as old as the history of medicine itself. Such fractures have been described by Hippocrates, Celsus, and Galen, as well as by almost all the writers of consequence who followed them. Under various names they have been recognized, and in various ways they have been accounted for, until it is no light work to follow the devious course which the current theory of their mechanism has pursued, since men's thoughts were first turned to this phase of the subject.

The earliest attempt to explain their mode of production was the fanciful one implied in the name *resonantia*, by which no more was signified than that in some way a fracture at a point opposite to that of a blow corresponded to the echo which was produced by a sound. The ancient term *contrafissura*—which is not convertible, as many have seemed to think, into the modern term *contre-coup*, or counterstroke, since the one signifies an effect, and the other a cause—throws no light whatever on the subject. But, about two hundred years ago, Boerhaave, and after him his commentator, Van Swieten, advanced a theory in regard to the mechanism of these fractures which, while incapable of the exact application which they gave it, is very suggestive as to some other phenomena of cerebral injury. They attributed fractures at a part of the skull opposite to that which had been struck, to the impact against the opposite wall of a column of the contents of the skull, which, from the amount of fluid the contents contain, they believed would have the physical properties of a column of water, one of the most incompressible of substances.

Then, a little over a hundred years ago, the attention of French surgeons was directed to what had come to be known under the general term *contre-coup*, by the offer, by the Royal Academy of Surgery, of a prize for the best essay on this subject. The result was a series of essays in which these remote fractures were generally explained upon the basis of the physical properties of the cranial bones, and principally upon that of the laws of the propagation of vibrations in solid substances. Of the writers of this time, Chopart attached considerable weight to the consideration that the skull may be considered as a solid box, the walls of which, under the influence of a blow, will be driven together in the direction of the force applied, and will be driven apart in the diameter which is at right angles to this one. Sir Charles Bell, in the beginning of this century, called attention to this same fact, and compared the disintegration which takes place in certain parts of the skull to that which may take place in an arch, the base of which is forced asunder by depression of the top. In 1844, Aran published, in the *Archives Générales de Médecine*, a paper on this subject in which he propounded a theory which is often spoken of as Aran's law, namely, that fractures of the base always begin in the vault, and reach the base by the shortest route, while lying wholly within a zone corresponding to one of the three great fossæ at the base.

In England, about this time, Mr. Hilton accepted the vibration theory of indirect fractures of the skull, and thought they reached the base under the influence of the architectural construction of the cranium, at the same time propounding the theory that vibrations which travel along certain lines to certain points are there lost by the interposition of soft structures, or by their discharge from the extremities of certain processes upon or into the cerebro-spinal fluid. Next, in Germany, the idea of the elasticity of the cranium as a whole began to attract great attention. In 1854, Bruns, of Tübingen, made some experiments which established what Chopart and Sir Charles Bell had assumed on theoretical grounds, namely, that the skull, under the influence of a blow, changes its shape. Other German investigators added confirmatory testimony, drawn from analysis of specimens of actual fractures. Then, in France, Félizet made an elaborate study of the subject of fractures of the cranium, and carried out a number of ingenious experiments, from which he concluded that almost all fractures of the skull start in the vault and travel toward the base, in lines which are determined by the restraining influence of several buttress-like portions of the bones—the nasal and occipital protuberances, the petrous bones, and the orbito-sphenoid prominences. Futhermore, he considered the basilar portion of the occipital bone with the two antero-lateral portions of the wall of the foramen magnum as a *pièce de résistance* which always remained intact.

After Félizet, the study of these fractures was taken up by Baum, who demonstrated by experiment the untenability of the pure vibration theory. Then Bergmann took it up, and advocated what may be called the elasticity theory, comparing indirect fractures of the skull to those which take place in the wall of the thorax, and to those of the eyeball

Digitized by Google

under pressure, as shown by Arlt. Then came the experimental investigations of Messerer and Hermann, which added considerably to the strength of the same theory. Next, von Wahl, resting his opinions partly on the work of his predecessors and partly on experiments and observations of his own, adopted and advocated the theory that fractures of the skull, with the exception of direct fractures, are caused by its being burst by expansion of the part which is equatorial to the axis of the force applied. After this Messerer returned to the study of the subject, and made a large number of experiments, the results of which completely refute the essential parts of the theories of Aran and of Félizet, and seem to confirm the theory which is now known in Germany as the *Berstungs Theorie* (bursting theory). Finally GREDER, in a paper which has prompted this article, "Experimentelle Untersuchungen über Schädelbasisbrüche," published in the *Deutsche Zeitschrift für Chirurgie*, March 9, 1885, has made still another study of indirect fractures of the skull, which seems to leave little doubt that these are, in the great majority of cases, due to the elastic properties of the cranium as a whole.

Of course, it will be understood that no intelligent student will fail to recognize—what was thoroughly recognized centuries ago—that fractures of the base of the skull are also caused by its being crushed in by force applied by the spinal column; in which case they are of the most direct sort imaginable. But a careful study of the valuable work in elucidating the mechanism of fractures of the skull, which has been done in Germany during the past five years can hardly fail to convince an unprejudiced student of the correctness of the theory which is advocated by Greder in the paper to which reference has been made. His experiments furnish a striking confirmation of the correctness of the bursting theory, which had been arrived at by both inductive and deductive reasoning. He tested it by applying regulated blows to skulls which were intact, and some of them still connected with the trunk, and he found that the fractures he produced lay in the lines which, according to the bursting theory, they should have occupied. His conclusions are: that the bursting theory affords a satisfactory explanation of indirect fractures of the base; that the fractures are parallel to the direction of the force which causes them; and that the extension of the fractures—or, to speak more accurately, fissures—is influenced by so many intercurrent conditions peculiar to each skull that it can, at best, be only suspected from the intensity of the violence which causes them. As to the point at which fractures of this sort start, he holds that it does not always lie in the point of impact, nor always in the equatorial line, but at that point in which the proportion of the resistance to the disruptive force is at a minimum. This, he thinks, will be found most frequently at the equator or near it.

We commend these views to those of our readers who are interested in the study of the mechanism of fractures of the cranium, and feel that it is especially important to call attention to them, and to those of which they form the natural sequel, since it would appear, from what is taught in most surgical works in the English language, that these very recent investigations of the Germans have not yet been fully appreciated by our own workers and writers. There may be a flaw in them; but, as they now stand, they seem to furnish a very satisfactory explanation of indirect fractures of the skull, and to present the convincing spectacle of a theory which, while arrived at partly by deduction, has been abundantly established by the test of experimentation.

EXPLORATORY INCISIONS IN THE DIAGNOSIS OF ABDOMINAL TUMORS.

TERILLON in the *Revue Medico-Chirurgicale des Maladies des Femmes* for May, in a paper read before the Society of Surgery of Paris, considers the subject of exploratory incisions for the diagnosis of abdominal tumors. He has collected 179 cases in which such incision was made: of these 39 died, and 140 recovered; and he, therefore, regards the "cures" as 79 per cent. But it is hardly just to consider exploration as a curative agency—it can only be said that exploratory incision was not fatal in 79 per cent. One interesting fact shown by Terillon's statistics is that an exploratory incision in malignant disease is very much more liable to be followed by death than if the disease be non-malignant.

Terillon observes that an exploratory incision ought to have one end, to make the diagnosis clear for the performance of a radical operation. It is for the surgeon who undertakes it the first step in a laparotomy, that has behind it an unknown, which must be discovered before passing further.

The exploratory operations collected by Terillon have been followed by a far higher rate of mortality than have those in the hands of Tait, Knowsley Thornton, Keith, Billroth, and other experienced operators.

PRIMARY CANCER OF THE VAGINA.

As is well known, primary cancer of the vagina is a rare affection, while it is very common for cancer involving the vaginal portion of the neck of the womb to extend to the vagina. In this extension of the disease the anterior vaginal wall is usually first affected, while the primary disease in most cases attacks the posterior wall. In the last fact we have a remarkable contrast between primary cancer and

Digitized by Google

cysts of the vagina, the latter more frequently affecting the anterior wall.

The *Centralblatt für Gynäkologie* of April 18th, contains reports of two cases of primary cancer of the vagina, one by GRAMMATIKATI, the other by MENZEL. The first patient was 27 years old, and the cancer was of the anterior wall; the second patient was 55 years old, and the disease was seated in the posterior wall. Each case was operated on successfully.

According to Grammatikati, there have been but 38 cases of primary cancer of the vagina published, to wit, 6 by West, 24 by Küstner, 3 by Schrœder, 1 by Grünewald, and 4 by Bruckner. These 2 cases added make the entire number 40. McClintock has remarked, that he has seen several cases of cancer of the vagina; but in all these cases the disease seemed to have extended from the vulva, or from the uterus. Yet it is quite possible that some of the cases where the uterus and vagina were both affected by the disease, and where it was supposed to have extended from the former to the latter, the reverse was the fact, the affection of the vagina being primary, that of the uterus secondary.

THE MOVEMENTS OF THE STOMACH.

ROSSBACH, of Jena, has been making some experiments, with a view to a better understanding of the movements of the stomach, derangements of which he believes to be at the bottom of many digestive troubles. The experiments were made upon dogs under the influence of profound morphia narcosis, and the results presented to the recent Congress für innere Medicine at Wiesbaden, and published in the *Deutsche med. Wochenschrift* for April 30th.

He has ascertained that as soon as the stomach is filled with food the peristaltic movements begin, at first feebly, increase gradually, and continue from four to eight hours. They occur only in the parts adjacent to the pylorus. The empty stomach is either entirely without motion, or exhibits only occasional and very feeble movements. The pylorus is closed during the entire period of digestion, and the emptying of the stomach begins suddenly when gastric digestion is, for the most part, accomplished. The duodenum is quite at rest during the entire period of gastric digestion.

SOCIETY PROCEEDINGS.

AMERICAN NEUROLOGICAL ASSOCIATION.

Eleventh Annual Meeting, held in the Hall of the Academy of Medicine, New York, June 17, 18, and 19, 1885.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, JUNE 17TH.—FIRST DAY.

AFTERNOON SESSION.

BUT a slight attendance of members was present when the meeting was called to order at 3.10 P.M. by the retiring President, DR. ISAAC OTT, of Easton, Pa. Dr. Ott made a brief address, alluding to the rapid strides made by neurological science, and the increase of knowledge concerning the physiology of the nervous system. If he might be permitted to allude to a subject upon which he had done some work, he would refer to

THE RELATION BETWEEN THE NERVOUS SYSTEM AND THE TEMPERATURE OF THE BODY.

The researches of various observers lead to the conclusion that the body temperature is controlled by the nervous system. The location of the centres is a subject of interest not only to physiologists, but to practitioners. Tscheschichin believed that a moderating centre existed in the brain. Eulenberg discovered a centre at the *sulcus cruciatus* which can cause a great rise in temperature, though he has lately attributed this action to a vaso-motor disturbance. In 1884 Dr. Ott had published a paper showing that centres having a relation to heat are located near the *corpora striata*. Within recent months he has attempted to map out these centres more definitely, and he finds them at the anterior inner part of the *optic thalami*. They must act either by increasing the production or diminishing the dissipation of heat. From his experiments, briefly described, Dr. Ott showed that there was an increased production, that the increment of heat was not due to vaso-motor deflections, and that the cerebral cortex was not the seat of the action.

Dr. Ott then introduced the Vice-President, DR. LEONARD WEBER, of New York, who took the Chair.

In accordance with the recommendations of the Council, Dr. Mason was elected as an

ASSOCIATE MEMBER,

his resignation as an active member being accepted.

Dr. Philip Zenner, of Cincinnati, and Dr. M. Allen Starr, of New York, were elected

ACTIVE MEMBERS.

A letter was read from THE PRESIDENT, DR. BURT G. WILDER, of Ithaca, announcing his inability to be present at the first day's session, and nominating DR. MILLS, of Philadelphia, as President for 1886.

The following nominations were made for

OFFICERS FOR 1886:

President.—Dr. Charles K. Mills, of Philadelphia.

Vice-President.—Dr. V. P. Gibney, of New York.

Secretary and Treasurer.—Dr. R. W. Amidon, of New York.

Councillors.—Drs. George W. Jacoby and E. C. Seguin, of New York.

The nominees were unanimously elected.

A proposed amendment to the Constitution, changing the

DATE OF MEETING

to the first week of May, elicited considerable discussion, and its further consideration was postponed to the afternoon of the next day.

An amendment providing that all business not of a scientific nature should be transacted in executive session after the conclusion of the scientific work, was adopted.

In the absence of Dr. Mills, his paper on *The Brain of a Delusional Monomaniac who Killed Several Per-*

sons, was read by title, and ordered to be published in the *Transactions*.

DR. A. D. ROCKWELL, of New York, reported

A CASE OF CHRONIC MYELITIS; RECOVERY.

He said that recovery from chronic myelitis supervening upon acute myelitis presenting marked symptoms, was so rare that a case purporting to be of this nature should be thoroughly sifted. He read the history of a case seen in consultation with Dr. Farrington. The patient was a girl of sixteen years, and the symptoms developed on her return from an excursion to the seashore, during which she had felt very much depressed, and for a great part of the day had sat upon a rock near the water, possibly becoming wetted and chilled. She suffered great pain, the lower limbs were completely paralyzed, and there was incontinence of urine and of feces. After six weeks a severe and intractable bedsore developed over the last lumbar vertebræ. In the early days of the attack she was restless and sleepless, morphine only aggravating the distress. After two weeks of persistent insomnia natural sleep returned. For these two weeks she was nourished with milk and champagne, as the stomach rejected all other food.

Dr. Rockwell saw her about three months from the beginning of the disease, after the acute symptoms had subsided. Electro-muscular contractility in the lower limbs was completely abolished. There was diminished electro-cutaneous sensibility, and sensation to contact was perverted. The sphincters were completely paralyzed. A highly unfavorable prognosis was given, but the father demanded that an effort should be made to improve his child's condition. The faradic current had been used previous to Dr. Rockwell's connection with the case, but of course without result. He applied the galvanic current to the spine and to the paralyzed muscles, using 30 Volts, and making the applications every other day. At first the only evidence of good was the healing of the bedsore. At the end of the fourth week, faint muscular contractions were noted, and after two weeks these had increased sufficiently to permit accurate determination of the reactions, which were the characteristic reactions of degeneration. Anodal closing contraction was greater than cathodal closing contraction. Rapid interruptions of the galvanic current failed to elicit any response. After two months electrical reaction was normal, the bedsore healed, and the paralysis of the sphincters was overcome. At the end of the fourth month the only trouble remaining was weakness of the flexors of the right leg.

At first this was a case of acute myelitis, afterwards, whatever the exact conditions of inflammation, proliferation of connective tissue, etc., there was evidently a tendency to degeneration and softening. The whole transverse area was involved.

Pathologically the value of the case is negative rather than affirmative; the damage had not progressed beyond reparation. Therapeutically it encourages us to persist in treatment. Four physicians, including the reader of the paper had pronounced the case hopeless, but the father insisted on every effort possible being made to secure recovery. In this connection Dr. Rockwell alluded to a case of infantile paralysis in which some years ago he had given the same unfavorable prognosis, but the mother clung to the faint shadow of a hope, until after four months' treatment approximate recovery ensued.

Dr. Rockwell then exhibited the patient whose history formed the topic of his paper.

DR. E. C. SEGUIN had been much interested in the paper. He was, however, not satisfied that this had been a case of transverse myelitis. It appeared rather to have been an anterior polio-myelitis, extending perhaps into the gray matter. It reminded him of several cases he had seen, in which the symptoms of anterior polio-myelitis were blurred by sphincter-paralysis, and diminution of sensibility. He understood that there had never been absolute anæsthesia as would have been the case in transverse myelitis. Hence, he did not consider that this case modified the unfavorable prognosis of transverse myelitis, a true case of which he had never seen recover. He had seen a case with symptoms almost as severe as this, in which recovery ensued after three or four years. There were pain, atrophy of the extremities, with partial paralysis of the sphincters. While the electrical applications undoubtedly assisted recovery in Dr. Rockwell's case, we must not forget that the time over which they extended was sufficient to permit spontaneous recovery.

DR. STARR inquired whether galvanism had been the sole treatment? Had there been applied a continuous current to the cord or an interrupted current to the muscles?

DR. BIRDSALL asked for a more explicit statement of the distribution of the paresis; and inquired as to the limitation of the sensory symptoms, and the facts concerning the skin reflexes and tendon reflexes. These are important points in diagnosis. There are conditions in which central transverse myelitis may occur with slight involvement of the lateral columns, and the sensory tracts of the posterior columns. From the symptoms stated, this does not appear to be a case of transverse myelitis, as there is no decided evidence of involvement of the lateral columns.

DR. ROCKWELL replied that no other treatment had been employed, that the current had been continuously applied to the spine, but in addition sharp and strong interruptions had been resorted to, in order to reawaken irritability by mechanical action. Applications were also made to the muscles. He had seen a great many cases of anterior polio-myelitis, and considered this typically transverse myelitis, except that there was not complete anæsthesia. All groups of muscles were affected alike. There was absolute loss of contractility in every muscle and every fibre. The sensory disturbances were slight and confined to the extremities. The patellar reflex was abolished in the beginning, but had now returned. In regard to ankle clonus, there was great agitation of the foot when strongly flexed.

DR. GIBNEY asked whether it is possible for the ankle clonus to persist when the patellar reflex is abolished?

DR. LANDON CARTER GRAY, of Brooklyn, said that it depends very much on what you call chronic myelitis whether or not recovery is to be regarded as remarkable; whether or not a case is to be pronounced hopeless on account of the symptoms remaining long after the period for spontaneous recovery appears to have passed. We do not know much of spinal pathology after all. We can diagnosticate anterior polio-myelitis,

Digitized by Google

or lesion of the columns of Burdach (locomotor ataxia), or of the lateral pyramidal columns. But researches of various observers show us that there are other columns with probably as distinct sets of symptoms, though their semeiology has not yet been elaborated. When we speak of myelitis we mean only that the disease does not involve one of the three known tracts, and may thus include, under one name, half a dozen distinct lesions, making it impossible to fix a limit to the period of spontaneous recovery. Dr. Gray had seen many cases last a long while, and finally recover; one case after a year. A case of lesion of the anterior horns had been quiescent for years. He gave an unfavorable prognosis and ordered faradism more as a placebo, to keep the patient coming to his clinic for purposes of demonstration, than in the hope of producing any good result. To his surprise, an improvement took place, that might be roughly characterized at fifty per centum. Thus, recovery is not so rare as Dr. Rockwell's experience would appear to have made him believe.

DR. ROCKWELL, in closing the discussion, said that the exact pathology of this interesting case cannot be decided. There appears to be a direct connection between the therapeutic measures and the recovery. It seemed impossible to him that after so many months of apparently progressive disease, spontaneous recovery could take place. More can be accomplished by persistent effort in cases of chronic myelitis and of infantile paralysis than has been the generally received opinion.

On motion of DR. AMIDON, Dr. M. A. Starr was invited to read his inaugural thesis.

DR. M. ALLEN STARR, of New York, exhibited specimens and read a description of

SOME RECENT METHODS OF STAINING NERVE TISSUES.

1. Weigert's hæmotoxylon method. This is the best for differentiating tissues. Sclerosed tissues do not take the stain, making it available for class demonstrations.

2. Weigert's acid fuchsin. This possesses no advantage; a combination of this and the hæmatoxylon gives good results.

3. Seguin's modification of the aniline blue stain. This is simple, and easily carried out, while inferior to Weigert's, as not permitting differentiation of the nucleus from the body of the cell; it stains sclerotic tissues prominently.

4. Sahli's method with methyl blue and acid fuchsin. Sahli claimed that it was possible to differentiate sensory and motor fibres by their different colorations, but to Dr. Starr this appeared to be an accident of time. Sahli had also described (5) a single stain with methyl blue.

6. Adamkiewicz's saffronine stain. Dr. Starr's results had been unsatisfactory. This method by selective action of the medullated structures renders it possible to map out certain regions in the fœtal brain, and had led to important discoveries.

Dr. Seguin explained the reasons that had led to the adoption of the method associated with his name. It permitted large transections to be handled and left over night in the stain. The ganglion cells and their processes come out well under the microscope, but its principal advantage was for demonstrations of gray and white matter, which are clearly differentiated. The reactions with pathological tissues are very satisfactory.

EVENING SESSION.

DR. GEORGE W. JACOBY, of New York, read a paper on

THE USE OF OSMIC ACID IN PERIPHERAL NEURALGIA.

The treatment of neuralgia by injection of a solution of perosmic acid in the neighborhood of the affected nerve was introduced by Neuber in 1883. He reported two cases, one of sciatica and one of trigeminal neuralgia, both cured after ten and twenty injections respectively. Eulenburg reports and tabulates twelve cases; of which three were cured, four more or less improved, five unaffected. The same observer records seven additional cases, of which four were cured. Reference was also made to the observations of Wölffler and Mercies. Dr. Jacoby made use of osmium tetroxide, OsO_4, known in this country as osmic acid. Perosmic acid, as it is called in foreign reports, is probably the same drug. He employs a one per cent. solution, of which one-half gramme to one gramme (5 mgr. to 1 cgr. of the drug) is injected into the connective tissue around the affected nerve as near as possible to the seat of pain. If the solution be exposed to the light for any length of time it becomes decomposed and discolored. Eulenberg says the discolored preparation may be still used, but in the reader's experience it is inactive. The solution should be recently prepared and dispensed in a colored vial; a small quantity only being prescribed at a time. Following the injection a severe stinging pain is felt, which lasts but a few seconds. Occasionally there are swelling and puffiness over the seat of puncture. In many cases a hard swelling lasted several days. There is no discoloration except where the needle enters the skin. The experiments of Franklin show the action of osmic acid thus used upon the living animal. There is an inflammation of the connective tissue and muscular structure immediately surrounding the nerve, and the nerve itself is blackened, osmic acid having the same action upon living nerve tissues as upon histological preparations. Dr. Jacoby reported eighteen cases, three of them in detail. Eight cases were cured, two improved, and eight unaffected. Of the eight cures five were cases of sciatica, all old ones. Of the eight unaffected, three were fresh cases and two were old. In one case of cervico-brachial neuralgia, treated with gratifying success, so far as the relief from pain was concerned, by injections over the musculo-spiral nerve, radial paralysis suddenly ensued. While it is true that an element of doubt existed, Dr. Jacoby attributed this to the injections. Arnozan calls attention to neuritis following injections of ether. In some of Franklin's experiments complete motor and sensory paralysis occurred in the domain of the nerves subjected to the treatment. Summing his experience, sciatica seemed the most amenable to this plan of treatment, and old cases afforded a better chance than fresh ones, contrary to the experience of Eulenberg. The pain following injection was almost unbearable in one case. This was opposed to the experience of European observers, who noted the absence of pain. Dr. Jacoby concluded:

1. That in osmic acid we have an agent serviceable in some cases of peripheral neuralgia.

2. That it is not an antineuralgic, and that its action is localized.

3. That it frequently fails where other agents succeed.

Digitized by Google

4. That it is dangerous to implicate a motor nerve in the injection.

On invitation, DR. SACHS, of New York, who had been in Berlin during the progress of Eulenberg's experiments, said that the latter's experience had been only partially satisfactory. He had gained the impression that the treatment is unreliable in most cases. The only good results he had seen were in old cases, principally of sciatica. In Berlin no pain followed the injections. In New York they were very painful. This might be due to the difference in the preparation employed. The injection of osmic acid is worth a trial in obstinate neuralgias after other methods have failed.

DR. SEGUIN said that he had not used osmic acid, but had had some experience in other methods coming under the same general plan of treatment, namely, that of deep-seated irritation by hypodermatic injections. This method was first published by Louton in 1864. Louton used various agents, principally recommending silver nitrate. Dr. Seguin treated one case in 1865, and in one in 1873 or 1874 by Louton's method, both successfully. In both abscesses occurred, one being very troublesome. Some years ago he published an account of some cases of malarial neuralgias treated by deep injections of quinine. There may have been some antimalarial virtue in the drug employed, but he believed the local irritation the principal factor in the result. Quite a variety of substances may be employed, and possibly less irritating agents may give good results. Numbness and paralysis may ensue from deep injections over nerve trunks, as in the case related by Dr. Jacoby. Two cases of damage to sensation, were known to Dr. Seguin, one occurring in his own practice and one in that of a friend. Both were trigeminal neuralgia, and were treated by deep injections of chloroform, as recommended by Bartholow. The injection was made too near the infraorbital foramen and persistent anæsthesia of the upper lip resulted. He had never seen motor impairment, but no doubt it could occur.

DR. JACOBY, in reply, said that he did not believe that counter-irritation was the sole factor in the cure by osmic acid. Eulenberg claimed that the drug was unirritating. Some change in the nerve took place, as demonstrated by the discoloration. Abscess had not occurred in any of his cases, nor in those of others. He would not recommend the indiscriminate employment of osmic acid, but he thought it well to know of the method, and to resort to it in cases similar to those reported to have been benefited.

DR. SEGUIN called the attention of members to the fact that Ranvier has successfully used osmic acid on living animals to demonstrate nerve filaments and fat cells.

DR. STARR exhibited some large sections stained by Weigert's method.

THURSDAY, JUNE 11TH.—SECOND DAY.

AFTERNOON SESSION.

THE PRESIDENT, DR. B. G. WILDER, of Ithaca, occupied the Chair.

DR. V. B. GIBNEY, of New York, reported

TWO CASES OF SPINA BIFIDA, CURED, ONE FOLLOWED BY HYDROCEPHALUS.

Excision of the sac is limited to a small number of cases. In ninety-five per cent. the sac contains portion of the cord and some portion of the spinal nerves as well. The method he recommended was aspiration followed by the injection of iodo-glycerine, also called Morton's fluid, which consists of potassium iodide half a drachm, iodine ten grains, glycerine one ounce. Both of his cases were successful. In one which died subsequently of hydrocephalus, the autopsy showed obliteration of the tumor. In the other, death occurred subsequently from cholera infantum, and he was unable to obtain an autopsy.

DR. L. C. GRAY, of Brooklyn, read a paper on

THE USE OF STRYCHNINE IN NERVOUS DISEASES.

Dr. Jewell in 1880 recommended the use of large doses of strychnine, in some cases up to one-tenth of a grain, in the treatment of myelitis. Dr. Gray referred to the uncertainty of diagnosis and ignorance of pathology in any affection of the spinal cord, outside of the three known lesions, of anterior polio-myelitis, disease of the columns of Burdach (locomotor ataxia), or of the lateral pyramidal columns. Other equally well-defined columns exist, with probably equally distinct symptoms. Dr. Jewell had overlooked these distinctions. Dr. Gray had made trial of strychnine for several years, though he had always been afraid to use the large doses advocated by Dr. Jewell. In two acute cases it was so badly borne, that he had not used it again in acute cases. In two subacute cases there had been sudden onset of alarming symptoms, in one apparently from cumulative effects, and for three days the case had continued to be a cause of great trouble and anxiety. In some more chronic forms of disease he had had greater success.

A case of general myelitis of traumatic origin had been treated at first with ergot and galvanism, afterwards with belladonna without result. Strychnine was given in doses of gr. $\frac{1}{50}$, increased to $\frac{1}{40}$, three times a day, galvanism being continued. The patient, who had paralysis of the lower limbs, soon walked with the aid of two canes, then with one cane, finally without a cane. Vesical paralysis also was overcome. Great improvement ensued in another case in which the paralytic symptoms followed miscarriage. In five cases of progressive muscular atrophy strychnine was given in doses gradually increased to gr. $\frac{1}{25}$ three times a day. The drug had a remarkable stimulating effect, promoting the sense of well-being, so that the patient felt the need of it when it was discontinued. One case took $\frac{1}{80}$ gr. to $\frac{1}{2}$ gr. thrice daily for a year. They all felt much better, but there was no real improvement. Weir Mitchell recommends strychnine in cases of neurasthenia, when about to get up from bed after undergoing the rest-cure. Dr. Gray had seen good results in such cases. In summing up, while the cases had been too few for dogmatic assertions, he had found great benefit in functional disorders, great improvement in some chronic cases, slight improvement in others, in two acute and two subacute cases alarming results. He had never felt safe in exceeding one-twentieth of a grain, and usually began with one-fortieth. He had not been able to dispossess himself of a scepticism as to the benefit to be derived from toxic doses. The paper was presented merely as a memorandum.

DR. DANA, of New York, said that he had had some interesting experience with strychnine in functional

Digitized by Google

nervous troubles. Three patients had taken very large doses. The case in which the drug had been best borne was one of depressing spinal irritation in a young man, compelled to abandon business by reason of physical and mental disability. Beginning with one-fifteenth of a grain thrice daily, the dose had been increased until one day over one grain had been taken in twenty-four hours. This produced slight effects, such as transient incoördination. This patient has now been taking over three-quarters of a grain in the twenty-four hours (four-fifteenths of a grain thrice daily) for more than four weeks, with great benefit. It is given in solution, and there is no doubt of the purity of the drug and the accuracy of the druggist. Two other patients are taking up to one-eighth of a grain and one-sixteenth grain, thrice daily, respectively. He finds these doses well borne in many cases, and has never seen cumulative or explosive effects. He finds that large doses of strychnine quickly relieve the pain and weariness in the back and neck, which is so early a symptom of nervous exhaustion; give tone to the sexual system; and are often efficient in the relief of insomnia where bromides and other sedatives have failed.

THE PRESIDENT, as a non-practitioner, would like to be enlightened as to the cause of the great difference in results obtained by two careful practitioners.

DR. SEGUIN did not see that our knowledge of the proper dosage of strychnine had been much advanced by the discussion. He had been taught, years ago, by Brown-Séquard that in functional nervous diseases large doses of strychnine were well borne. He has repeatedly given $\frac{1}{15}$ grain thrice daily; and after the first week or two does not hesitate to push it. Here he entirely agreed with Dr. Dana. In reference to the plan of Dr. Jewell, he agreed with Dr. Gray that it is risky and dangerous, especially in cases of uncertain diagnosis. He had suggested at the time of the discussion in 1880, that the absence of tetanic symptoms in Dr. Jewell's cases might be explained by the fact that there was no motor gray matter left. In transverse and central myelitis, strychnine is ill-supported, even in moderate doses. In chronic cases he has never dared to give heroic doses; he has used moderate doses, with not over-satisfactory results. He thinks the best means to avoid error is by giving the drug hypodermatically, and closely watching its effects. In a nervo-mimetic case, diagnosticated as locomotor ataxia by an eminent *confrère*, he had given $\frac{1}{15}$ grain thrice daily without toxic symptoms and with rapid improvement.

In reply to the President, Dr. Seguin said that he had never seen cumulative effects. He had been told of one case in a hysterical male subject, and he had to credit the alarming dyspnœa in that case to hysteria.

Dr. DANA suggested that the explosive effects in the case alluded to by Dr. Gray might be explained by the fact that in this case the Doctor had given the drug in pill form, while in the others it was administered in solution.

THE PRESIDENT, DR. BURT G. WILDER, of Ithaca, then delivered his *address* upon

PARONYMY VERSUS HETERONYMY AS NEURONYMIC PRINCIPLES.

The paper, which was quite lengthy and full of elaborate philological details, set forth the existing imperfections in neurological language, and advocated that plan of revision, which, with the minimum of disturbance of existing terms, might introduce accuracy and simplicity in the accepted terminology. He proposed to discard all vernacular names, and select the shorter classical technical ones; abbreviating some by dropping non-essential words, and others by substituting prefixes for adjectives, as medicommissura for commissura media. The great hindrance to anatomical study is the large number of existing terms. A recent collection of those of five languages gives more than 9000 names for less than 500 parts of the brain. The first principle of the new system is the use of mononyms instead of polynyms. It is then proposed to associate conventional or anatomical groups by the use of similar terms. indicating locality by prefixes such as *pre*, *post*, and *medi*. To obviate the objections fairly taken against an exclusively Latin terminology, the system of paronymy is applied—that is, instead of a more or less literal translation into the vernacular of a Latin or other technical term (heteronymy), an English dress is to be given the Latin or Latinic term, as commissure for commissura, peduncle for peduncula, etc. From the selection of the best technical terms, and their modification in this manner, while an English form is given to them they are still readily recognizable by scholars of all nationalities, and the objections against heteronymy, namely, ambiguity, length, literal inaccuracy, and lack of dignity, are obviated.

FRIDAY, JUNE 19TH.—THIRD DAY.

AFTERNOON SESSION.

DR. E. C. SPITZKA read a paper on

THE RELATIONS BETWEEN THE SYMPTOMS AND THE LESIONS OF POSTERIOR SPINAL SCLEROSIS.

An elaborate analysis of the symptoms associated with lesions of various portions of the cord, was presented and illustrated by microscopical sections. Dr. Spitzka was inclined to look upon many lesions as secondary, and the disease in many cases as local rather than systemic.

DR. SEGUIN, in response to an invitation from the President, remarked that nothing can be added to a paper that so admirably presents a comprehensive summary of our present knowledge. He had made some physiological observations, and he would like to ask Dr. Spitzka what bearing they had upon the question of the location of the initial lesion in spinal sclerosis. The point he had noticed was the insusceptibility of tabetic patients to the sensory disturbances of aconitine. Out of some nineteen patients there was but one who had experienced any tingling, and that patient took $\frac{6}{100}$th of a grain of aconitine in twenty-four hours, inducing serious symptoms of poisoning. The general systemic effects were very severe, but the tingling was absent, while in other patients it is usually the first effect noticed. He believes that this subjective tingling originates in the gray matter, and is referred to the periphery. It is said that aconitine acts on the peripheral nerve-endings. If that is the case, he does not understand how we can account for this absence of effect in tabetic patients, as we usually consider these sensations independent of conduction, as in the cases of subjective pain referred to amputated limbs. His

Digitized by Google

observations are as yet incomplete, but he inclined to the belief that they indicate an early change in the gray matter.

DR. SPITZKA replied that one aspect of Dr. Seguin's observations puzzled him. He could not account for the absence of tingling in the face. Dr. Seguin's explanation of early lesion of the gray matter would hold good so far as concerned the affected extremities. He did not believe that a single drug of this class acted upon the periphery, but this question might easily be settled by an amplification of Dr. Seguin's experiments, that is, the administration of aconitine to patients with peripheral disease. He was of the opinion that the primary lesion is in the gray substance.

DR. B. G. WILDER called attention to

A SELDOM DESCRIBED ARTERY OF THE BRAIN,

A. termatica, which he said was always present. According to Gray and other anatomists, the two anterior cerebral arteries have a connecting link, the anterior communicating, whereas, according to Dr. Wilder, this is usually absent, the anterior cerebrals joining one another directly. It is from the point of juncture of these two vessels that the arteria termatica is given off. It is the only azygos artery in the brain. In regard to nomenclature, he proposed to substitute the names precerebral, medicerebral, and postcerebral for the anterior, middle, and posterior cerebral respectively.

DR. WHARTON SINKLER, of Philadelphia, contributed a paper on

TWO CASES OF FRIEDREICH'S DISEASE.

(See page 3.)

DR. SEGUIN has published five cases in *The Medical Record*. In this disease there is distinct paresis, and a tendency to contracture of the muscles of the leg. One of his cases has equinovarus, the tendo Achillis being strongly contracted. There is no anæsthesia and no pain, and yet there is degeneration of the whole of the posterior columns of the cord. As to the differential diagnosis, there is but little difficulty in distinguishing this disease from disseminated sclerosis. There is none of the peculiar tremor that belongs to the latter disease. It is distinguished from tabes dorsalis by the absence of pain and by the age, Friedreich's disease occurring in children. The ataxia of the lower limbs is very imperfect and not characteristic as in tabes. No treatment has any effect.

DR. AMIDON said that he had a case of this disease under treatment, the patient being a girl aged eleven years. She commenced to walk at eight months, had an attack of whooping cough followed by paraplegia. This disappeared at the end of three months. At the present time the patient is bright, not hysterical, and has no bad habits. She is of normal size. The skin is thick and bound down to the subcutaneous connective tissue. Her gait is ataxic; there are no ocular symptoms, and no pain. The reactions to electricity are normal; the patellar reflex is absent.

DR. STARR: Dr. Friedreich considered this disease due to a congenital deformity of the cord. There is no cerebral degeneration.

DR. G. W. JACOBY exhibited two new instruments: 1. An improved galvanometer. 2. A graphite instrument.

Much discussion followed as to their usefulness, resulting in the appointment of a committee to secure some absolute standard for the measurement of electricity.

EVENING SESSION.

DR. SPITZKA gave a demonstration of a *Brain Monstrosity*.

DR. SEGUIN read a paper entitled

A CONTRIBUTION TO THE PATHOLOGY OF THE CEREBELLUM.

The patient, an army officer, was first affected in 1867. He came under Dr. Seguin's treatment in 1877. The disease began with very severe headaches and one or more epileptiform or apoplectiform attacks. These were characterized by an impending loss of consciousness, but he never fell. He had no vertigo. In 1868 he consulted Dr. Agnew for failing sight. There was no diplopia. There were optic neurosis and partial atrophy.

After this the headache continued as the chief symptom. He had no return of the attacks and no symptoms in the legs. A seton was placed in the back of the neck, and in the course of a year (1868) the headache disappeared. In 1869–1870, the patient began to notice a gradual loss of power in the legs. There were no peripheral pains. From 1871 to 1874 the patient was in Europe. Legs and head were troublesome; no anæsthesia, no distinct paralysis; sight impaired but not getting worse. The patient had an appearance of hebetude. Returned to the United States in 1874 and since then has been in *statu quo*. Has lately had diplopia for distant objects; is pale and thin, but has had less headache. He has no ataxia, and walks with his feet apart. There was no vibration during rest. No marked change occurred until a few months before the fatal result, a few months ago. Then some difficulty with articulation and deglutition, stupor and death with cerebral and bulbar symptoms. Patient died comatose.

Post-mortem examination. The vertex of brain was pale and flabby. Base: Olfactory bulbs normal, optic nerve smaller and dull yellow. Carotids stiff, gaping, and the seat of marked arteritis. Other arteries at base in same condition, the basilar being the most diseased. No thrombi anywhere. Posterior aspect of cerebellum revealed a large cyst, two inches in diameter, occupying the sight of the vermiform process. Fourth ventricle was not diseased. Cyst lay mostly in the right hemisphere; it was monolocular and contained a clear fluid. The lateral ventricles were dilated. Spinal cord: The veins were much injected, varicose, and more numerous than normal. The cervical and dorsal enlargements were normal except a doubtful grayish appearance in the right postero-lateral columns. The cord seemed small for the size of the subject. The heart was hypertrophied and its walls much thickened. The aorta was atheromatous but not calcareous. The patient was of a peculiarly frank disposition, and there was absolutely *no history of syphilis*.

DR. AMIDON gave the history of a case of cerebellar tumor in a child of six. The mother had been the subject of sarcomatous glands of the neck, which had been removed by operation. One year after, the child, then five years of age, had an attack which resembled tubercular meningitis except that there were no convul-

Digitized by Google

sions. There had been the regular prodromata of this disease. There were moderate ptosis and moderate strabismus. The child was under the influence of potassium bromide, but was tossing violently. Speech was almost abolished. The optic nerves were probably not much affected, as the child recognized his mother across the room. The patient remained free from fever. At the end of a week the diagnosis of tubercular meningitis was given up. The patient developed great muscular weakness, progressive stupor, incontinence, and finally died comatose. The head was rather hydrocephalic.

Post-mortem examination showed a sarcomatous tumor in the cerebellum involving the front ventricle.

After some general discussion the Association adjourned to meet next year at the same time, the place of meeting to be hereafter announced.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, June 15, 1885.

THE PRESIDENT, CHARLES A. LEALE, M.D., IN THE CHAIR.

DR. FRANK H. HAMILTON presented a paper entitled

A FEW PRACTICAL REMARKS ON RUPTURE OF THE PERINEUM.

It is unjust, he thought, to say that this accident can always, or even generally, be prevented by the skill of the accoucheur, since its occurrence is often due to conditions and circumstances over which he has no control. Having enumerated some of the causes which may determine this result which are wholly beyond the power of the accoucheur to remove, he referred to the advice given by various authorities in regard to the management of the perineum. As to the usual direction to "support the perineum," he stated that he would venture to say that the idea cannot be sustained by any sound mechanical theory or by experience.

If the purpose of making pressure upon the perineum, however, is to carry the head forward towards the pubes, the suggestion has a meaning, and can be understood; and he thought this is advisable whenever, from lack of curve in the sacrum and coccyx, or from any other cause, the vortex does not take this direction. Still, these examples are rare and exceptional. A lacerated perineum is sometimes caused, he continued, by the improper haste of the accoucheur, who seeks to expedite labor by the use of ergot or some other similar agent, or by unnecessarily resorting to the use of instruments. Some modern gynecologists do not think the danger of rupture of the perineum is increased by the use of the forceps, if only they be used skilfully; but he thought it certainly must increase the danger if the instruments are used unskilfully, and where, in the hands of even the most skilful, the instrument is retained in position until the head has entirely escaped from the vulva. Nor did it appear to him that the argument in their defence is conclusive, even when they are only employed to bring the head into the lower strait and then withdrawn. It is claimed, he said, that by this simple manœuvre the process of natural labor may often be greatly expedited; but this is the very thing which it is generally most desirable to avoid, so that, as Meigs says, the perineum may not be taken by surprise.

In this connection, Dr. Hamilton remarked that since the time when he commenced the practice of medicine, the question of instrumental labor has undergone a complete revolution. "I was a pupil of Dewees," he said, "and was taught that the forceps were seldom required; but to-day the teaching is altogether different, and there are now many gynecologists who count their instrumental labors by the thousands. A young man who was urging me to apply the forceps to his patient, but in which case the result proved that it was unnecessary, told me that a friend of his, a recent graduate of one of our city schools, and who was doing a large obstetrical practice in a neighboring town, assured him that that he never put a woman to bed without forceps. I do not hold this young man's teachers responsible for his practice, but the fact illustrates what is now the drift of professional opinion."

He next spoke in condemnation of the general use of anæsthetics in parturition at the present day, remarking that their effects are by no means in all cases limited to the alleviation or abolition of pain when employed in this class of cases. Not infrequently they increase the frequency and strength of the uterine contractions, and this is especially apt to happen when they are given in small quantities and in the first period of their exhibition; so that they may thus contribute to the production of a hernial rupture. In other cases under their influence he has seen the uterine contractions temporarily suspended, and long-continued inertia with resulting delay in the expulsion of the placenta and hemorrhage ensue. Dr. Hamilton concluded this portion of his subject in the following language: "While there can be no doubt that the forceps and anæsthetics have been of incalculable service to parturient women, I have a strong conviction that, since they have come into such common and almost universal use, they have done a great deal of harm. I believe the time is not distant in the future when it will become apparent to all that we have in these matters progressed too rapidly, and possibly that our progress has been altogether in the wrong direction."

Having referred to the various degrees of rupture of the perineum, he said that the concurrence of a deficient perineum and of prolapsus uteri does not always stand in the relation of cause and effect. The perineum in its most perfect condition does, and when the uterus occupies its normal position, gives no direct support to the latter, and the uterus may be made to descend from many causes, whether the perineum is sound or not, while if in its descent it has been brought into actual contact with the perineum, the presence of the latter is an important obstacle to its further protrusion. The absence of the perineum, when the vagina and uterus are in their normal condition, can only influence the descent of the uterus by first inducing atony of the muscular fibres of the vagina, with congestion and prolapse of the vaginal walls, by which not only the full and indirect support which the perineum gives to the uterus is removed, but the vaginal walls become actually a dead weight to drag the uterus downwards. These consequences to the vaginal walls and to the uterus, however, by no means always ensue upon the total destruction of the perineum.

Dr. Hamilton said he could not agree with some modern gynecologists that it is better in such cases to

Digitized by Google

proceed at once to close the rent by sutures. The parts have suffered such a degree of stretching and contusion as to render the occurrence of inflammatory reaction, if not of sloughing, almost inevitable, while the lochial discharges will make it impossible to keep the parts clean. In addition, the operation itself inflicts a severe injury when the condition of the patient is already critical from other causes; and, finally, under judicious management, the rent frequently becomes partially and sufficiently closed spontaneously. If spontaneous closure of any portion of the rent takes place under these circumstances, it is probably not usually effected by the direct contact and immediate adhesion of the lacerated surfaces. The surgeon encounters sufficient difficulty in securing this result, even when, at a later day and under much more favorable circumstances, and after an extensive denudation of the surfaces, he attempts the closure by the aid of sutures. It is much more probable, he thinks, that the union occurs in these cases by the secondary process of granulation. The parts need not be unnecessarily or forcibly drawn asunder, but they may be carefully exposed to view each day, and made clean by gentle ablution; while the urine should be drawn by a flexible catheter as often as required. In further support of the opinion that an immediate operation is not in most cases, if any, advisable, he thought it should be explained more fully that, if it were possible to secure union by adhesion at this early period, the operation must be made within a few hours at most. Hewitt had expressed the opinion that the primary operation should be performed within one hour from birth; believing that it is of little use to insert sutures when the labor has been on some hours. "But," said Dr. Hamilton, "one may ask Mr. Hewitt what is to be done with that very considerable number of cases in which the expulsion of the placenta is delayed beyond an hour? Shall the rent be closed before it is expelled, at the risk of the sutures being torn by its subsequent passage? Or is the accoucheur again to interfere with the course of nature, and, with more or less violence, as may become necessary, remove the placenta without reference to the present general condition of the patient or of the uterine contractions?" Since it is proposed to make the operation under every surgical disadvantage, and when the patient, prostrated and trembling from the results of a severe labor, is in the worst possible condition, both mentally and physically, to endure the shock of an operation, or even its announcement, he believes that nothing but the most urgent imperative necessity can justify the operation under these circumstances, while this necessity has not been shown to exist. At this early period, also, it is often difficult for an expert even to form anything like a definite opinion as to the actual extent of the lesion. A rent, which at first seems to be an inch or two in length, on account of the distended condition of the perineum, will, after contraction a few hours later, be found to be not more than a quarter or half an inch.

He then passed on to speak of the secondary operation, and having referred in passing to the preparatory treatment, gave the details of the operation as follows: The patient being anæsthetized and placed in the usual position for lithotomy, while an assistant displaces the upper wall of the vagina with a Sims or Bozeman speculum, the surgeon will proceed with mouse-tooth forceps and scissors to divide the surfaces which are to be brought into contact. These surfaces should be extensive, rarely less than one inch in the antero-posterior direction; and they should extend inward along the vaginal wall nearly as far. The denudation must also be complete, the interposition of the smallest portion of the mucous membrane or integuments between the lips of the wound being sufficient partially or wholly to defeat the operation. All bleeding having ceased, three well-waxed sutures, of the largest size of harness-makers' silk, are to be introduced, the first being placed at the angle of the wound close to the sphincter. The needle, armed with a double ligature, must be inserted at a distance of from three-fourths of an inch to one inch from the margin of the wound, carried to a sufficient depth to include the entire surface which has been made raw, and brought out at a corresponding point upon the opposite side. Each suture will be introduced in the same manner. Sections of a large-sized flexible bougie, one inch longer than the fissure, are laid upon either side, and the double sutures drawn upon until the lips of the wound are brought together with moderate firmness, when the sutures are tied. In most cases, in order to secure accurate apposition of the margins of the wound, it is well to insert two or three very delicate superficial sutures. The knees of the patient should then be tied together lightly, and with a small pillow interposed between the knees.

Having spoken of the after-treatment, he said that in case the rent involves more or less of the recto-vaginal wall, the difficulties of the operation will be greatly increased, and it will be advisable always to paralyze the sphincter by two lateral incisions, extending backward and outward on each side, as first recommended by Baker Brown. He said, in conclusion, that he had made no reference to the use of the wire suture in this operation, because he preferred to employ the so-called "quilled" suture, because he did not find the wire so easy to introduce or to remove, while he had not found it to possess advantages in any other respect. If, however, the rent or loss of structure involved any considerable portion of the recto-vaginal septum, he would recommend, so far at least as the rectal fissure is concerned, the wire suture, either with or without Bozeman's clamp.

After the reading of his paper was completed, Dr. Hamilton made a few supplementary remarks. Dr. Fordyce Barker said that he employed chloroform for the purpose of preventing perineal rupture; explaining its agency in this connection in two ways. The first explanation was that it relaxes the muscular fibres of the sphincter vaginæ. Dr. Hamilton, however, regarded this as a physiological error, not to say absurdity. When the sphincter is distended to such an enormous degree as is the case when the head is pressing upon the perineum, it is impossible for any constitutional measure, such as the administration of chloroform, to have any effect in relaxing the tension. The second explanation was that the uterine action was somewhat suspended by the chloroform, and to that extent relieved the perineum. Dr. Hamilton said that this was satisfactory as far as it went; but when the head advanced, this influence would have no effect. On the whole, therefore, he regarded the use of chloroform as an unnatural interference with labor.

Digitized by Google

As to the frequency of a perineal rent of a serious character, Meigs, in the fifth edition of his work, page 54, says: "I defy any one to show me from my own practice, a case of durable rent of the perineum." The expression *durable* Dr. Hamilton understood to refer to such a rupture of the perineum as would require surgical interference. It would not do to ignore this and say that Prof. Meigs was an old practitioner; for here was not a theoretical idea, but a *fact*. Yet he was a practitioner who very seldom employed instruments, and who, like his predecessor, Dewees, very seldom, if ever, resorted to anæsthetics.

Finally, Dr. Hamilton referred to a letter which had recently appeared in the *Medical Record*, describing the Vienna obstetrical service. In the Vienna Lying-in Hospital are confined every year about nine thousand patients, and yet the mortality is less than one-half of one per cent. "The entire absence of medicine," says the writer, "to hasten the labor when too slow, or relieve severe pains, or to induce them when wanting or feeble, is noticeable. Avoidance of every kind of interference in labor is carried to the greatest extreme. Even for forceps operation, or a version, unless extremely difficult, no anæsthetic is administered. Great care is taken also to prevent the least injury to the os uteri. The utmost respect is paid during labor to this part. It must dilate normally, and in its own time. Artificial dilatation is not permitted even with the finger, and all mechanical appliances for dilatation are 'inventions of the devil.'"

DR. AUSTIN FLINT read a paper on

PERSISTENT FLATNESS OVER THE LIVER AS PROOF THAT ACUTE DIFFUSE PERITONITIS IN NOT ASSOCIATED WITH INTESTINAL OR GASTRIC PERFORATION.

(See page 1.)

DR. CHARLES S. WARD read a paper on

INTUSSUSCEPTION OF THE INTESTINES, WITH THE REPORT OF A CASE.

The case was that of a child eight years of age, in which general peritonitis and excessive tympanitis supervened. The following was the course of treatment adopted: Large enemata of warm water, with the position of the body nearly reversed, repeated every three hours, and sometimes with a few drops of turpentine or of essence of peppermint in the water; one granule every hour containing one-tenth of a grain of calomel; about one-eighth of a grain of morphia every three hours, or, at all events, enough to relieve the pain and procure some rest; ice *ad libitum;* milk and beef-tea in small but frequent doses; hot water stupes constantly applied and frequently changed. Recovery ensued, but convalescence proceeded very slowly, and it was not until four weeks from the time of the attack that the child was able to sit up in bed and take sparingly of solid food. Pain and vomiting, followed by great prostration, were easily excited, and the greatest care had to be taken. During the latter part of the illness ipecac, with spiced syrup of rhubarb, was given three times a a day.

Having related a case in an infant eighteen months old, successfully treated without operation, as reported by Dr. Collier in the *Lancet*, Dr. Wood made some general remarks on the affection and its treatment. In regard to laparotomy, he said, after having briefly reviewed the literature of the subject: "I have thus presented a few of the many statistics scattered through our works and medical journals, for the purpose of showing how extremely uncertain in its results is the operation of laparotomy for the relief of this distressing malady, especially in children, who easily succumb from so serious an operation by shock at the time of its performance, or inflammation, which usually follows. The surgical interference in the case of adults, for impediments other than the one under consideration, gives better hopes of success, and should be adopted, as so eloquently advocated by the late lamented Sims, in a paper read before the Academy of Medicine a short time before his death, in which he urged the importance of the operation in all cases that were not promptly relieved by other means, owing to the great advantages we have at the present day, as compared with even a decade since, by virtue of the power of antiseptics carried out to its logical sequences.

THE PRESIDENT made some remarks on

A METHOD OF DIRECT LOCAL TREATMENT FOR DISEASES IN THE REGION OF THE ILEO-CÆCAL VALVE, AND ALSO FOR THE SAFE REMOVAL OF IMPACTIONS OF THE INTESTINES.

On many occasions during the past twenty years, he said, while observing the intense pain and great danger to life arising from accumulating flatus in the intestines in cases of idiopathic and traumatic peritonitis, obstructions at the ileo-cæcal valve, hypertrophy and retroversion of the uterus, causing obstruction at the rectum, also where there were tumors and the lodgement of foreign bodies, the contraction of adhesions, etc., he had longed for a means of giving exit to the imprisoned air. Fifteen years ago he resorted to colocentesis in these cases, by introducing a long capillary needle—twice the thickness of the usual hypodermic needle and six inches long—quickly through the walls of the abdomen into the inflated bowel. By this means the gas escaped, but it gave, as a rule, only temporary relief, and as the intestinal obstruction still remained reaccumulation of the flatus nearly always followed.

Dr. Leale then exhibited a long flexible rubber tube, which could be readily attached to an ordinary fountain syringe, and said that early in June he had been able to relieve by means of it a lady who was dying from the pressure upon the heart and lungs of a large accumulation of intestinal gas. There was an impaction of the intestines which was gradually removed by the injections. The tube passed fifty-nine and a half inches into the bowels, and he had reason to believe that its extremity actually went through the ileo-cæcal orifice. Before inserting the tube it was advisable to introduce a large rectal speculum, which would prevent a retroverted uterus or other obstruction from interfering with the passage of the tube. When it is desirable to apply a remedy, such as bismuth, for instance, to any part of the intestinal tract, it can be added to the water to be injected through the tube.

DR. H. M. BRIGGS presented some interesting pathological specimens. The first of these was

A HEART WITH ABUNDANT VEGETATIONS IN ALL FOUR OF ITS VALVES.

This, he said, is exceedingly rare, and he had never heard of another case. In the two hundred cases tabu-

Digitized by Google

lated by Dr. Osler, in his recent Gulstonian lectures, there was no instance of this kind. The other specimen was a female bladder, containing a large calculus (apparently of oxalate of lime), and exhibiting old cystitis and trabecular hypertrophy. The ureters were dilated, and the kidneys were the seat of well-marked pyelonephritis and other disease.

DR. ISAAC E. TAYLOR spoke on the subject of Dr. Hamilton's paper, and said in commencing that the views expressed in it were to a large extent in consonance with his own. The whole subject of the management of the perineum, he thought, is one of great simplicity. His practice is not to touch the perineum, but to prevent its rupture by the judicious management of the head of the child whether in the cavity of the pelvis or emerging. The shoulders, he believed, are much more apt to produce laceration of the perineum than the head. The forceps are not as frequently the cause of rupture as Dr. Hamilton seemed to think; but, at all events, the manner in which they are used has a good deal to do with it. A great variety of methods have been proposed for the management of the perineum during parturition, but, as a rule, they are neither cleanly, philosophical, nor physiological. The correct plan is, he thought, to place the fingers entirely back of the perineum, on the part between the rectum and the coccyx. In this way direct pressure can be made upon the child's forehead, and the perineum saved by delivering the head between the pains. Placing the fingers in this situation also enables the accoucheur to prevent rupture of the perineum in occipito-posterior positions by changing them to face presentations. As he had remarked, great care should always be taken in the delivery of the shoulders on account of their liability to cause a rupture. In regard to the use of anæsthetics, he said that he always went to his obstetric cases provided with both chloroform and ether. He had long since noticed that in a certain proportion of cases, chloroform had the effect of putting a stop to uterine contractions, and in these instances he had found that ether almost always had a very happy effect in bringing on the pains again. If one of the anæsthetics did not answer, therefore, he would try the other, and its action generally proved satisfactory. Like Dr. Hamilton, he did not approve of the immediate operation in ruptured perineum; believing that, as a rule, it is much better to wait for three or four weeks after the birth of the child. It is a fact that the severe effects of labor not infrequently produce a paresis of the perineum which gives it an appearance closely resembling a laceration; but which in a few hours, or in some cases a longer period, entirely passes away.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 18, 1885.

THE PRESIDENT, A. JACOBI, M.D., IN THE CHAIR.

DR. H. W. MITCHELL read a paper entitled

OBSERVATIONS ON THE OPERATION FOR LACERATED PERINEUM, WITH DEMONSTRATIONS AND CASES.

His opening remarks were devoted to the anatomy of the part and to the effects of laceration, such as rectocele and cystocele, and that annoying dragging sensation so often complained of, which tends constantly to grow worse. Some have claimed a spontaneous cure of the lesion by tying the patient's legs together; but he had never seen any except a very partial union under these circumstances. When the parts are torn, the proper thing to do is to restore them to their original integrity; and this is possible by means of a simple operation which can be performed by any physician of ordinary skill. Having spoken of the preparatory treatment, he described the common operation of denuding the surfaces of the lacerated tissues and uniting them by means of deep silver wire sutures. Formerly he had been in the habit, according to the general custom among surgeons, of drawing the wires through by means of a silk loop; but more recently he had adopted the plan of threading the needle directly with the silver wire, and he considered this in every way preferable. He made it a point always to insert the finger into the rectum as a guide when passing the sutures. He thought it well to employ as few sutures as would answer the purpose desired. He employed a curved needle, and inserted and brought out the sutures through the skin at some little distance from the edges of the wound. Having secured the deep wire sutures by twisting them together with moderate tightness, he passed one or more superficial silk sutures to approximate the edges of the skin. The urine was drawn with a catheter before the patient left the table.

In five out of forty cases in which he had operated during the last fifteen months, he had used carbolized water as an antiseptic dressing, but in the other thirty-five he had employed no antiseptic whatever. He said that all the operations had been attended with complete success, and that union by first intention had resulted in every instance. The after-treatment consisted in keeping the parts scrupulously clean and the bowels confined for the first six days; the patient in the meanwhile living upon a light diet. On the sixth or seventh day the sutures were removed.

In case there was also a laceration of the cervix requiring treatment, he operated on that at the same time as the perineum, the cervical sutures being allowed to remain until the eighth or ninth day. When the sutures are removed, the patient is permitted to get up, and when she first does this it is sometimes found that there is a slight paresis of the lower extremities resulting from the want of action on the part of the muscles during the time that she was confined to bed. This usually lasts but a few hours, but in exceptional cases may remain for several days.

In all the forty cases it was the secondary operation that was performed, and in nearly one-half of the entire number there was laceration of the cervix, upon which he operated also. It is his practice to sew up the cervix with the patient in Sims's position, and then to turn her on her back for the perineal operation. In two of the cases the rupture of the perineum was associated with complete procidentia uteri; one of the patients being 76 years of age, and the other 65. In the case of the older of the two, before operating on the perineum, he amputated the whole neck of the uterus, according to the method of Dr. Isaac E. Taylor; and in both instances a perfect result was obtained. One of the other cases operated on was that of a lady six months pregnant, who insisted on having the operation per-

Digitized by Google

formed on account of the great discomfort from which she suffered in consequence of the ruptured perineum; and when the ether was given her, the fœtus in utero was also anæsthetized, the effect of the drug remaining for several hours. This patient then went on to full time, and the new perineum stood the strain of the labor perfectly well. After narrating the forty cases seriatim, Dr. Mitchell announced a number of conclusions derived from his study of them. The most common cause of laceration of the perineum he found to be the incompetence and carelessness of midwives, who attend so many women of the lower classes in their confinements.

DR. ALFRED C. POST thought it wiser to keep the bowels open regularly after the operation. By doing this the patient is rendered more comfortable, and the functions of the body generally are more satisfactorily performed. He thought it decidedly objectionable to have an accumulation in the bowels, such as results from keeping them confined for six or seven days, and he believed it is now the practice of the best gynecologists to see that after the operation the bowels are opened every day. As to the operation which Dr. Mitchell had employed, it certainly seemed to have been very successful in his hands, but for himself he preferred the plan which he had described before the Academy a short time before, of simple incisions (without denuding the mucous membrane), and then bringing the parts together by means of two flaps, one looking upwards and the other down toward the perineum.

DR. MALCOLM MCLEAN said that he was surprised to hear the author of the paper say that he had discarded the silk loop and threaded his needle directly with the silver wire. He believed it much preferable to use the silk loop, and this procedure is almost universally adopted among gynecologists. At the present day the curved needle is decidedly antiquated. It is impossible to guide it with accuracy, and the short straight needle is used almost altogether in place of it. By elevating the parts it can always be inserted with perfect precision. Another point: where the sutures are inserted through skin as well as mucous membrane, a very serious amount of pain is almost invariably caused. Yet Dr. Mitchell had expressly stated in almost every instance in narrating his cases that the patient was free from pain after the operation; and he would like to know how he explained this.

DR. SIMON BARUCH said that he fully agreed with Dr. Post as to the advisability of keeping the bowels open. The old method of keeping them confined had now to a great extent been given up, and for this step in advance the profession was indebted to a gentleman of this city, Dr. Hanks. He also had the same objection to the curved needle that Dr. McLean had, viz., that it is impossible to guide it accurately. The author of the paper, however, certainly deserved credit for his attempt to simplify the operation as he had done, since it is highly desirable that every practitioner should feel himself capable of performing it whenever the occasion may arise. He was also glad to see that he condemned the doctrine that the perineum is in any source a support to the uterus. On this subject he believed that Emmet's views are entirely correct. As to having the sutures through the skin, he thought this must necessarily give rise to more or less pain. It was like the operation for hemorrhoids, before Allingham's method was adopted, when it was always requisite to use opium freely in the after-treatment. In Emmet's new operation all the sutures are within the line of the muco-cutaneous fold of the vulva, and it is followed by no pain whatever. While, however, Emmet's operation is, he believed, the best in many respects that has yet been devised, it is a difficult one to describe satisfactorily, and he feared, therefore, that it will not be as widely understood and become as popular as it deserves to be. In the operation employed by Dr. Mitchell very little of the rectocele seemed to be taken in, and while it is no doubt an excellent operation in comparatively recent cases, this, he thought, is a serious objection to it in many older ones. Still, the results in his hands, according to the reports which had been made, are certainly very creditable to him. As to discarding the use of the silk loop, he could see no satisfactory reasons for doing this.

DR. MITCHELL said, in reply, that with the plan which he had adopted, no inconvenience whatever is experienced from keeping the bowels confined. The night before operating he always orders some efficient laxative, and in the morning this is followed by an enema. As the food taken during the days succeeding the operation is always of a very light character, there is consequently little accumulation of fecal matter in the bowels. As to the reason why there was so little pain after his operations, he could not say, but such was the fact, and he thought it a mistake to suppose that the passage of the sutures through the integument necessarily gives rise to pain. In surgical procedures in other parts of the body, it is very common to pass sutures through the skin, and yet in many of them this is not followed by any special pain. In regard to the curved needle, he said that with the finger in the rectum he had found that its direction could be guided perfectly and without any difficulty, and he thought it decidedly preferable to the straight needle. There is no necessity whatever for lifting up the parts with the tenaculum. When the silk loop is used in connection with the wire suture, a larger needle is required, and altogether he thought this procedure complicated the operation and made it seem difficult. One great objection to Emmet's operation is, that it is not sufficiently simple, and his experience had shown that, by this simpler one, described in the paper, a torn perineum can be perfectly restored, which is the particular object in view.

DR. JOSEPH A. ANDREWS read a paper on

CONTAGIOUS CONJUNCTIVITIS: ITS CAUSE, PREVENTION, AND TREATMENT.

In the earlier part of it he gave the results of practical investigations made by himself in the report of a case of successful inoculation of the conjunctiva with a pure gonococcus culture of the seventh generation. It was not, however, in a healthy eye, the patient suffering from pannus and other trouble. Three weeks previously he had inoculated the conjunctiva of the same individual with a pure culture of a coccus found in healthy saliva, but with an entirely negative result. After the gonococcus inoculation, however, the eye presented a perfect picture of gonorrhœal conjunctivitis. Having given a *résumé* of the results obtained by other obser-

Digitized by Google

vers in similar experiments, he went on to eak of oph ia neonatorum. While the infection is often received directly from the vagina of the mother at the time of birth, he believed that more frequently it is contracted somewhat later and through other channels. It has been ascertained that normal lochial discharge does not produce blenorrhœa. When a child is the subject of the disease, there is danger of its infecting the whole household, and it is necessary that great care should be observed to avoid this.

In speaking of granular conjunctivitis, he said that Sattler claimed to have produced this affection by inoculation; but in this he believed that he was probably mistaken. Personally, he had not been able to find cocci of any kind in over fifteen hundred cases in which he had made careful examinations. The secretion is apparently the carrier of the contagion; but it requires special conditions, such as are liable to result from overcrowding, improper diet, and bad hygienic surroundings generally, for its development.

As ophthalmia neonatorum is sometimes contracted directly from the vaginal secretions, it is advisable that the parts of the mother should be very thoroughly cleansed before the birth of the child. When there is reason to fear infection, the eyes of the infant should be washed with a saturated solution of boracic acid, and a two per cent. solution of nitrate of silver also applied. Credé's method of prophylactic instillation has been followed with excellent results. In addition to the two per cent. nitrate of silver solution he uses a solution of salicylic acid. Up to 1880, when he first began the practice, the disease attacked no less than ten per cent. of all the infants at the Leipsic Lying-in Hospital; but since this plan has been adopted there has been only about one case a year, out of from three to four hundred children born.

DR GARRIGUES for several months had had a two per cent. nitrate of silver solution applied to the eyes of all new-born infants in the Maternity Hospital on Blackwell's Island, and out of 351 children, had not a single case of the disease. He did not state in his report, however, whether any of the mothers were infected. In Dr. Mundé's service at the same institution, the two per cent. solution was used upon 80 children without a single case of the disease; while in Dr. Murray's service, in which a one per cent. solution of nitrate of silver was employed, ten or twelve out of fifty infants were attacked. It is claimed by Credé and others that the one per cent. solution is not sufficiently strong to prevent the affection.

Post-natal infection, as he had said, is, in his opinion, more common than infection at birth, and it is derived from the mother through the agency of sponges, towels, etc. In any case, therefore, when there is danger of infection it is best to keep the child entirely away from the mother except at the time of nursing. Ophthalmia neonatorum is a disease which prevails principally among the poorer classes, and he believed it the duty of physicians to warn dispensary patients and others of its danger, as they had the opportunity. In regard to the statistics of contagious ophthalmia in some of the asylums of New York, as presented by Dr. Daily, at the last meeting of the Academy, he thought that the percentage would have been still larger if he had included public school children in his figures.

The conclusion of the paper was devoted to the treatment of purulent conjunctivitis. The first thing to do is to wash away any infecting material, and the second to render the conjunctival surface as nearly as possible antiseptic. Injections should be used for several minutes at a time, after which a two or four per cent. solution of nitrate of silver should be applied. If the latter strength is employed, it is advisable to follow it with a solution of chloride of sodium to neutralize it. Boracic acid and vaseline make an excellent dressing, and iced cloths should be kept applied to the eyes. If there is much swelling of the eyes, the outer canthus should be cut. Dr. Andrews exhibited an eye speculum he had devised, which was made hollow, so that by attaching to it a fountain syringe irrigation could be practised in a very satisfactory way by means of it. A three per cent. solution of carbolic acid could be used in the case of adults. From four to twelve per cent. solutions of nitrate of silver may be required according to the urgency of the case.

CHICAGO MEDICAL SOCIETY.

Stated Meeting, June 1, 1885.

THE PRESIDENT, C. T. PARKES, M.D., IN THE CHAIR.

DR. E. FLETCHER INGALS read a paper on

HAY FEVER, ITS CAUSES AND CURE,

in which he said this disease had been the subject of investigation since it was discovered by Bostick, in 1819, but only recently has the profession arrived at satisfactory conclusions as to its etiology and treatment. The disease is met with commonly in southern England and the United States, rarely in Europe, and never among the natives of Asia and Africa. It is an aristocratic affection, being found more commonly among the residents of villages and cities, and the opulent, rather than farmers and the poor, notwithstanding the theory that it is caused by the pollen of grains.

Hay fever usually makes its appearance about the middle of August, and lasts until the first frosts of autumn. During an attack the mucous membrane covering the turbinated bones is greatly swollen, usually congested, the congestion often extending to the palate, fauces, pharynx, and conjunctiva. Microscopic examinations of the secretions have revealed numerous vibrios, which were formerly thought to be the cause of the affection, but it is more probable that their presence is accidental, as they may usually be found in the nasal secretions at other times. The pollen of plants acts as causes, not *per se*, but as exciting causes, being irritants to an exhausted nervous system. This nervous exhaustion renders the nasal nerves peculiarly susceptible to irritant substances. The theory of the nervous origin of hay fever has been generally accepted by the profession, although it has been only recently established that the tract involved is limited in the majority of cases to the lower turbinated bones and the lower and back part of the septum. In a considerable number of cases the sensitive areas are even more limited, though in some cases the middle turbinated bodies are involved. The sensitive areas are not uniform in different cases.

After referring to the symptoms and diagnosis of the affection the treatment was discussed. Weak solutions of quinine had been applied to the diseased regions, on

Digitized by Google

the theory that this drug would destroy the minute organisms which were formerly supposed to be the cause of the affection. While this remedy had proven efficacious in some instances, it was found that weak solutions of soda, or other non-irritating drugs, had proven as efficacious. Many remedies have been vaunted as specifics in the treatment of this as in that of other intractable, self-limited diseases, and they have been found sadly wanting in curative properties.

Internal remedies that are of value are tonics and antispasmodics, and local remedies which sometimes give relief in the onset of the disease, are weak solutions of quinine, carbolic acid, tincture of opium, powders of morphia, bismuth, iodoform, etc., but they are not curative. For the asthmatic symptoms we can use the remedies appropriate to spasmodic asthma. However, it is only recently that we have found a method of treatment which promises to cure nine cases out of ten, and a remedy which promises to relieve the distressing symptoms in a fully developed case of hay fever. The latter is cocaine. Its action is such that it promises to be very valuable in the palliative treatment of the dis ease. A case of idiosyncratic catarrh, which closely resembles hay fever, came under Dr. Ingals's observation recently. A two per cent. mixture of cocaine and starch was blown into the nose as soon as the paroxysms came on. It gave immediate relief, and was repeated as the attacks recurred. About two weeks after another attack supervened, and the same treatment gave relief. Cocaine will doubtless prove to be a remedy of great palliative power in this affection.

Successful treatment by the galvanocautery, which was first thoroughly tried by Dr. Roe, had, previous to last May, been applied by Drs. Roe, Allen, and Sajous, to about thirty cases, about eighty per cent. of which were reported cured. As the disease is caused by a peculiar sensitiveness of the terminal branches of the sphenopalatine ganglion and nasal nerve, which are distributed over the septum and turbinated bodies, the treatment to be effectual must remedy this hyperæsthetic condition. The means adopted for accomplishing this purpose consist in applications of glacial acetic acid, carbolic acid, and other escharotics, and searing the membrane with the galvanocautery. The chemical agents often fail, but the galvanocautery, properly used, seldom fails. Successful treatment with the galvanocautery requires from ten to twenty sittings, and should be completed before the attack comes on. The method used is first to examine the nasal cavity with a slender, flat probe, by which the sensitive spots are located, and then the cold electrode is passed into the parts, and having reached the point to cauterize, the electricity is turned on whereby the wire is heated. It is applied for the fraction of a second to the diseased tissue, causing a small superficial burn. This operation is repeated at intervals until all sensitive spots have been relieved, care being taken not to burn too large a surface, else severe inflammatory action may ensue. When skilfully performed the operation causes little pain, and if cocaine is applied previously, no pain will follow. If no anæsthetic is used, the pain may be relieved by spraying the parts with Dobell's solution. In conclusion, nearly all cases may be cured by systematic, thorough, superficial cauterization with the galvanocautery of the hyperæsthetic portion of the nasal mucous membrane, providing the treatment is carried out between the attacks. Care must be taken to cauterize every sensitive spot, and not too much at once. The operation may be made painless by cocaine, and this drug may give relief during the attacks. General treatment must not be neglected.

Dr. Ingals then exhibited the battery which he uses, which is a large one of the ordinary pattern. He said it was necessary to have a good battery with a large amount of reserve force, so it can be used without the necessity of frequently agitating the fluid. The fluid must be often renewed.

DR. F. O. STOCKTON thought more prominence might have been given to the causal relation of hypertrophied turbinated tissue to hay fever. In all cases of hay fever he had met he had found hypertrophic nasal catarrh. If we treat hay fever, why not also treat the hypertrophic catarrh which is a causal factor in the disease? He always removes the hypertrophied tissue on this account. In all other points he agreed with the writer, especially in the use of cocaine. Since this drug came into use, he has used it in several cases which resembled hay fever with good results. It gave more relief than quinine, belladonna, or any other drug.

DR. ROBERT TILLEY protested against the use of the term hay fever when it is shown it does not depend on the pollen of hay exclusively as a cause. He thought a better term to be idiosyncratic coryza, as it is caused by a multiplicity of circumstances. That morning a patient had visited him in whom the symptoms were almost identical with hay fever, and if they had arisen at the proper season it would have been so diagnosticated. He is a grocer, and the attacks occur whenever he has to handle coffee. Dr. Tilley used cocaine in a four per cent. mixture with bismuth, and it gave immediate relief. He has often in cases of hay fever performed scarification of the inferior turbinated bones and mucous membrane of the septum with good results. He applies first a little cocaine, and very little bleeding follows. With reference to the locality of the sensitive areas in the nose, he thought that certain indefinable pathological conditions of the mucous membrane gave rise to the sensitiveness which may be found in any region where the mucous membrane is in a pathological condition.

DR. G. F. HAWLEY remarked that in passing the Eustachian catheter when it reached the posterior part of the turbinated body, it often produced a reflex cough even in healthy persons. He had one patient in whom asthmatic symptoms occurred the moment this region was touched, and after the removal of hypertrophied tissue by the Jarvis snare the asthma disappeared. Hay fever may be a neurosis or the result by reflex action of disease existing elsewhere. Mackenzie, of Baltimore, relates a case of a young woman who had ovarian disease and had attacks of hay fever during each menstrual period. On examination of the nose there was found a small piece of hypertrophied tissue at the posterior extremity of the inferior turbinated bone, not large enough to obstruct the naris or give rise to any troublesome symptoms of itself, yet when it was removed the hay asthma disappeared forever. It would be hard to define the relation between this tumor and the diseased ovaries which caused monthly attacks of hay asthma, but it seemed to exist.

DR. INGALS stated that he is of the opinion that a

Digitized by Google

careful examination of every case of hay fever will disclose the presence of a sensitive area. In the case quoted in which the hay fever occurred during the menstrual periods, it was stated that there was a sensitive spot which when irritated gave rise to the asthmatic symptoms. After cauterization the mucous membrane heals in about ten days. A small spot the size of a dime or nickel should be cauterized and then allowed to heal perfectly before another cauterization.

MONTREAL MEDICO-CHIRURGICAL SOCIETY.

Stated Meeting, June 12, 1885.

VICE-PRESIDENT, EDW. H. TRENHOLME, M.D., IN THE CHAIR.

CANCER OF RECTUM WITH SECONDARY AFFECTION OF STOMACH.

DR. R. J. B. HOWARD exhibited the stomach and intestines of a patient who had recently died at the Montreal General Hospital. The history of the case is as follows: James W., aged 63, had for some time had pain referred to bladder, and was sent into the hospital under Dr. Fenwick, on suspicion of having stone in the bladder. In December, 1884, he began to suffer pain over pubes, slight and limited in area, increased on lying down. This pain increased steadily in intensity, and in April last patient gave up work on this account. At this time there was frequent micturition, both day and night, but urine presented nothing unusual. He now began to lose flesh rapidly. Some three weeks before admission he had some retching and on three occasions vomited. On admission into the hospital June 2, 1885, the above symptoms were present. It was found that the stream during micturition was sometimes arrested, and that the act was attended by pain. No stone was detected in the bladder, and as urine contained some pus, and his prostate was enlarged, he was put on treatment for cystitis. Nothing was discovered when examining prostate per rectum, except the enlargement of that gland. Two days later he had an alarming attack of collapse, and recovering from this, symptoms of pneumonia appeared, of which disease he died on June 9th. Before this a hard tumor was detected in the epigastrium, which was believed to be malignant disease of the pylorus, or possibly the liver. The man was much emaciated, and had a very cachectic appearance.

Necropsy.—Pnemonia of left lung and œdema. In abdomen all the glands in omentum were enlarged, some the size of a walnut, hard and firm. The gastro-colic omentum was puckered up and contained a large nodular mass. Ascending colon bent on itself, and held down by a large mass of new growth, which appeared to originate in the glands of the meso-colon. Sigmoid flexure turned up and fixed to transverse colon by another nodule of cancerous tissue, and lower down, opposite the third lumbar vertebra, adhered to a large mass formed between the layers of the mesentery. The abdominal viscera were removed *en masse*, and on further dissection an ulcerated surface the size of a man's palm, was found occupying the posterior aspect of the lesser curvature of the stomach, and its wall was slightly infiltrated; the pancreas was also involved in this growth. In several other places the walls of the bowel were the seat of similar new growths, usually attacking them from without, and starting from between the layers of the mesentery. All the mesenteric and retro-peritoneal glands were enlarged, firm, and evidently the seat of the same new growth. On the anterior wall of the rectum, corresponding to a mass the size of a bantam's egg, seated in wall of rectum and adherent to the bladder just above the prostate, was an ulcer the size of a ten-cent piece, having raised, rolled ridges, and a somewhat depressed base. The ulcer was about four inches from anus, and no enlarged glands were found below this. Veins of prostatic plexus filled with old clot. Arteries normal. Bladder, with exception of enlarged prostate, normal.

Dr. Howard remarked that this was another of those cases where there was extensive disease of stomach without symptoms. The original disease, without doubt, commenced in the rectum, and extended upwards to the stomach through the glands. He also said that it is most unusual for malignant disease of the rectum to spread so rapidly, and from so slight a local affection to become general carcinoma. The symptoms caused by moderate enlargement of the prostate were more prominent than those caused by the extensive malignant disease.

NEWS ITEMS.

CHICAGO.

(From our Special Correspondent.)

THE MEETING OF THE NEW COMMITTEE ON THE ORGANIZATION OF THE INTERNATIONAL MEDICAL CONGRESS.—The New Committee appointed by the American Medical Association, at its recent session at New Orleans, met at the Palmer House, Chicago, at noon on Wednesday, June 24th. There were present Drs. R. Beverly Cole, of California; J. V. Shoemaker, of Philadelphia; W. H. Wathen, of Louisville; John B. Hamilton, of the Marine-Hospital Service; George F. French, of Minneapolis; F. L. Sim, of Memphis; X. C. Scott, of Cleveland; Robert Battey, of Rome, Ga.; J. S. Billings, of Washington; E. F. Upham, of West Randolph, Vt.; I. Minis Hays, of Philadelphia; Ellsworth Eliot, of New York; E. P. Cook, of Mendota, Ill.; D. A. Linthicum, of Helena, Ark.; D. W. Stormont, of Topeka, Kan.: J. S. Lynch, of Baltimore; George A. Ketchum, of Mobile; A. Y. P. Garnett, of Washington; F. W. Beard, of Vincennes, Ind.; A. H. Wilson, of South Boston, Mass.; A. R. Smart, of Hudson, Mich.; N. F. Essig, of Plattsburg, Mo.; William Pierson, of Orange, N. J.; J. W. McLaughlin, of Austin, Texas; G. Baird, of Wheeling, West Va.; Nicholas Senn, of Milwaukee; and W. E. Duncan, of Ellendale, Dakota.

Dr. Cole, as temporary Chairman of the new committee, called the meeting to order, and, on motion, Dr. William Brodie, of Detroit, President of the American Medical Association, and Dr. N. S. Davis, editor of the *Association Journal*, were invited to join in the deliberations of the Committee.

The resignation of Dr. Austin Flint, of New York, as a member of the Committee, was presented and accepted, and Dr. J. W. S. Gouley, of New York, was elected to fill the vacancy, and he took his seat with the Committee.

Digitized by Google

The Committee then proceeded to effect a permanent organization, and Dr. Cole of California, was elected Chairman, Dr. J. S. Lynch, of Baltimore, Vice-Chairman, and Dr. Shoemaker, of Philadelphia, Secretary.

Dr. X. C. Scott, of Cleveland, moved that the Chairman appoint a subcommittee of nine to prepare a revision of the rules and preliminary organization of the Ninth International Medical Congress, as published at Washington in 1885, and that this subcommittee report their revision to the Committee at its evening session on the 24th of June. Adopted.

The Chair appointed the subcommittee as follows: Dr. X. C. Scott, of Ohio; Dr. Wathen, of Kentucky; Dr. Billings, of U. S. A.; Dr. Shoemaker of Philadelphia; Dr. Hamilton, of U. S. Marine-Hospital Service; Dr. Upham, of West Randolph, Vermont; Dr. Gouley, of New York; Dr. McLaughlin, of Austin, Texas, and Dr. Linthicum, of Helena, Arkansas.

At the evening session the subcommittee asked for further time, which was granted, and the Committee adjourned to meet the next morning at 9 o'clock.

On Thursday morning Dr. X. C. Scott, presented the report of the subcommittee, which was adopted.

The principal change in the Rules was in that regarding membership. It was modified so as to read, "The American Members shall consist of delegates from the American Medical Association, and from Medical Societies in affiliation with the American Medical Association, each of said societies being entitled to one delegate for every ten members." This alteration reducing the membership of the Congress to the constituency of the American Medical Association, and excluding the large majority of the profession from admission to the Congress, was opposed by Dr. Billings, on behalf of the original committee, but without avail.

Rule 12, making presidents of the Sections *ex officio* members of the General Committee, was stricken out.

The organization of the Congress was then elected as follows:

Dr. Austin Flint was retained as *President*. Dr. Henry I. Bowditch, of Boston, was stricken from the list of *Vice-Presidents*, and there were added Drs. John L. Atlee, of Lancaster, Pa.; O. W. Holmes, of Boston; W. O. Baldwin, of Montgomery, Ala.; J. M. Toner, of Washington; Wm. Brodie, of Detroit; L. A. Sayre, of New York; W. W. Dawson, of Cincinnati; and H. H. Skillman, of Lexington, Ky.

Dr. John H. Packard, of Philadelphia, was elected *Secretary-General*, and Dr. F. S. Dennis, Chairman of the *Finance Committee*.

The Executive Committee was constituted as follows: Drs. Beverly Cole, of Cal., Chairman; J. V. Shoemaker, of Philadelphia; A. Y. P. Garnett, of Washington; J. H. Packard, of Philadelphia; F. S. Dennis, of New York; J. S. Lynch, of Baltimore; J. W. S. Gouley, of New York; William Pierson, of Orange, N. J.; Christopher Johnston, of Baltimore; and J. C. Tucker, of Alameda, Cal.

A *Local Committee of Arrangements* was also appointed, consisting of Dr. A. Y. P. Garnett, of Washington, Chairman, and all of the Washington members of the Committee and of the Councils of the Sections.

In the Section of *Medical Education, Legislation, and Registration*, Dr. S. E. Chaillé, of New Orleans, displaced Dr. H. P. Bowditch, of Boston, as President, and Drs. George Cupples, of Texas, and R. J. Dunglison, of Philadelphia, were substituted as Vice-Presidents or Drs. Chaillé and Stillé, of Philadelphia.

In the Section of *Anatomy* Dr. C. W. Kelly, of Louisville, and Dr. W. H. Pancoast, of Philadelphia, were added as Vice-Presidents.

In the Section of *Physiology* Dr. H. P. Bowditch, of Boston, was added as a Vice-President.

In the Section of *Medicine*, to which that of *Nervous and Mental Disease* was added, Drs. Alonzo Clark, of New York, S. Weir Mitchell, of Philadelphia, and P. G. Robinson, of St. Louis, were added as Vice-Presidents.

In the Section of *Surgery*, Dr. Moses Gunn, of Chicago, was added as a Vice-President.

The Sections of *Obstetrics* and *Gynecology* were united, and Dr. Battey, of Rome, Ga., made President, and Drs. T. A. Reamy, of Cincinnati, John Goodman, of Louisville, Thomas Opie, of Baltimore, and T. Gaillard Thomas, were added to, and Dr. Thomas Addis Emmet, of New York, was stricken from the list of Vice-Presidents.

In the Section of *Ophthalmology* Dr. E. Williams, of Cincinnati, was substituted for Dr. Henry D. Noyes, of New York, as President, and Dr. Noyes and Dr. E. L. Holmes, of Chicago, were made Vice-Presidents.

In the Section on *Otology*, Dr. C. H. Burnett, of Philadelphia, was stricken from the list of Vice-Presidents and placed on the Council, and Drs. A. M. Wilder, of San Francisco, and D. S. Reynolds, of Louisville, were made Vice-Presidents.

In the Section of *Dermatology and Syphilis*, Dr. J. M. Keller, of Hot Springs, Ark., was made Vice-President.

In the Section of *Laryngology*, Dr. Lefferts was displaced as President, and Dr. J. N. Mackenzie, of Baltimore, substituted, and Dr. M. F. Coomes, of Kentucky, was made a Vice-President.

In the Section of *Public and International Hygiene*, Dr. Ezra M. Hunt, of Trenton, N. J., was stricken from, and Drs. J. L. Cabell, of Virginia, A. L. Carroll, of New York, and J. N. McCormick, of Bowling Green, Ky., were added to, the list of Vice-Presidents.

In the Section of *Military and Naval Surgery and Medicine*, Drs. Donald MacLean, of Ann Arbor, P. A. Hooper, of Arkansas, and E. H. Gregory, of St. Louis, were made Vice-Presidents.

In the Section of *Practical and Experimental Therapeutics*, Dr. E. R. Squibb, of Brooklyn, was added as Vice-President.

In the Section of *Diseases of Children*, Dr. Abraham Jacobi, of New York, was stricken out as President, and Dr. J. Lewis Smith, of New York, substituted, and Dr. DeLaskie Miller, of Chicago, was added as a Vice-President.

Numerous changes and additions were also made in the Councils of the various Sections.

THE INTERNATIONAL MEDICAL CONGRESS AND THE MEDICAL PROFESSION OF PHILADELPHIA.—A meeting of the members of the medical profession of Philadelphia concerned in the organization of the International Medical Congress of 1887, was held at the Hall of the College of Physicians, on Monday, June 29th, Dr. Alfred Stillé in the Chair. Dr. David W. Yandell, of Louisville, was present by invitation.

Digitized by Google

After hearing a report of the proceedings of the new Committee, at its meeting held in Chicago last week, and after considering the changes in the organization which were made, including the restriction of the scope of the membership by which a large proportion of the profession of the country would be excluded from the Congress, the following preamble and resolution were unanimously adopted:

Whereas, Certain serious changes have been recently effected in the preliminary organization and rules for the International Medical Congress of 1887, it has seemed desirable for the members of the General Committee and the officers of the Sections resident in Philadelphia to meet for consultation; and

Whereas, It has appeared that these changes are inconsistent with the original plan, and detrimental to the interests of the medical profession in America, and of the International Medical Congress; therefore, be it

Resolved, That we, the undersigned, consider that our duty to the profession and to ourselves requires us to decline to hold any office whatsoever in connection with the said Congress as now proposed to be organized:

D. Hayes Agnew,	S. Weir Mitchell,
Roberts Bartholow,	William F. Norris,
John H. Brinton,	William Osler,
Charles H. Burnett,	John H. Packard,
R. A. Cleemann,	Theophilus Parvin,

I. Minis Hays,	William Thomson,
William W. Keen,	James Tyson,
Joseph Leidy,	Horatio C. Wood,

David W. Yandell.

PROFESSIONAL OPINION ON THE INTERNATIONAL CONGRESS ORGANIZATION.—The second day of the meeting was ushered in by a somewhat verbose discussion regarding the action of the committee relative to the International Medical Congress. From our best information regarding the gentlemen who were instrumental in initiating this uncalled-for windstorm, we fancy the trouble originated from disappointment. They are sore-heads of the "rule or ruin" type. Some of these men have for years endeavored to supply the wind-power for the American Medical Association meetings. The International Medical Congress requires a more reliable power—a steadier power; hence these dress-parade sort of fellows were, of necessity to the welfare of the Congress, relegated to the rear.

In order to conceal the true character of the charges, they hid behind the New Code prejudices, charging that New Code men were put on the committees. However objectionable the New Code men may be, we hope they are governed by purer principles than men whom we know to be ostensibly sticklers for Old Code theories, but are practically no-code practitioners, except such as will give them personal aggrandizement.

We have carefully looked over the "rules and preliminary organization," and can see no reason to find fault with the action of the committee. We feel entirely satisfied that they have acted in the best interest of the American profession in general. Nearly all the States, the District of Columbia, and Canada, have been represented by the appointment of prominent and distinguished physicians on the committees and sections. New York, having the largest number of widely known men, is justly entitled to a larger number of representatives. A few States are left out, which can be the only tangible objection to the appointments. It must not be forgotten that the States so largely represented are those in which most of the medical teachers and authors reside, without whom, be they Old or New Code men, the American profession could not be represented in its best light, which, above everything of a technical nature, should be sought after.

Judging the whole matter from an unprejudiced standpoint—although some features may savor of suspicion—we think the committee acted in the best interests of the medical profession, and we are pretty certain that the auxiliary committee of thirty-five, appointed at the New Orleans meeting, will not undo any of the work of the original committee, but will lend their good counsel towards perfecting the work already begun, of making the Congress highly creditable to the medical profession of the United States. To this end we hope they will work in perfect peace and harmony.—*Kansas City Medical Record*, June, 1885.

The question of spelling Nation with a big N, came up at New Orleans, at the meeting of the American Medical Association, and appears to have been decided in the negative.

It seems that last year a committee was appointed to invite the International Medical Congress to hold its next meeting here. This committee was instructed, in case the invitation was accepted, "to act as an Executive Committee, *with full power* to fix the time and to *make all necessary and suitable arrangements* for the meeting of such Congress." The words which we have italicized would seem to indicate beyond a peradventure that the Association intended to give the Committee *carte blanche* in relation to the whole affair. The Committee was successful in getting the Congress, and accordingly proceeded to carry out its instructions, as given above, by appointing the officers of the different sections and the various necessary subcommittees. We received the list of appointees some time ago, and failed to find anything to criticise. We thought the names had been selected with great care, to secure men of, as far as possible, National, if not International, reputation.

But not so with all. The Committee had made no provision for the eloquent champion of the pap-chewing mothers of Texas; they had ignored the oleates; they had not tested all their appointees by the *shibboleth* of the Code; they had not given the "rural deestricts" their *numerical* ratio of the offices; whole States and Territories were entirely ignored; even Ohio had but fourteen, and of these her metropolis had all but one, while New York, Philadelphia, and Boston were liberally remembered. And so there was a kick. And so it was decided to increase the size of the Committee, and otherwise so arrange matters that the ranches of Texas, the prairies of Kansas, the mines of Colorado, and the forests and wheat fields of the great Northwest should all be "represented" among the officers of this Congress.

Verily, we trust the original Committee, and their rustic accessories, may duly exercise, the former pa-

Digitized by Google

tience, the latter humility, and both moderation, to the end that the Congress may be a success; for unless they do this we greatly apprehend the "kick" will overturn "the fat into the fire."—*Columbus Medical Journal*, June, 1885.

We were as strongly opposed as any to the sectionalism which appeared in the appointments by the original Committee, but that this Committee were vested with all power to do just as it did, seems very clear under the resolution which created it. That being the case, the wisdom of the Association, to say nothing of its right, in nullifying the work already done in the way of organizing the Congress, does not seem clear. An authority on parliamentary law to whom we have submitted the whole question, declares that the Association has clearly committed an error in its meddling with the original committee. But whether it was justified or not in thus seeking to undo what was done in good faith, is a comparatively trivial matter. The great injury it has done the profession of this country, of which the American Medical Association is but a fraction, by making it appear in the eyes of our European brethren as a quarrelling, querulous agglomeration, will make any victory which the Association may gain over the original committee, too dearly bought. Whether the original committee will succumb remains to be seen. If it should not, the confusion will be worse confounded. —*Medical Age* (Detroit), June 25, 1885.

THE PLYMOUTH EPIDEMIC.—The regular monthly meeting of the American Society of Public Analysts was held at the rooms of the Health Department, Brooklyn, on June 22, 1885, the President, E. H. Bartley, M.D., in the chair.

Dr. Cyrus Edson, of the New York Health Department, who recently visited Plymouth with Dr. Taylor and Mr. Martin, as a Committee from the New York Board of Health, read a paper on the "Plymouth Epidemic of Typhoid Fever; its Origin and Results." The paper was illustrated with lantern views, from photographs taken by Mr. Martin, and these views gave a very accurate idea of the condition of affairs in the town.

Dr. Edson's paper, although written independently of the essays of Dr. L. H. Taylor, which have recently been printed in THE MEDICAL NEWS, endorses the opinions stated by the latter gentleman, which is, that the origin of the epidemic could be traced to the case of typhoid fever in the Davis family, living near the reservoir.

In the discussion which followed, and which was carried on by many prominent physicians and health officers, the unanimous opinion expressed was to the effect that the constant spread of the disease during the past month was due to carelessness. When the character and origin of the disease were known there was no excuse for the neglect of disinfection, especially of the discharges. It was found that the wells, which previously had not been polluted, would soon become contaminated with the excrement, which is often thrown into shallow privy-vaults. The prevalent opinion was that, if rigid sanitary laws were not enforced immediately, the epidemic would continue to spread.

Mr. E. W. Martin, chemist to the Board of Health of New York, presented a table of analyses of the reservoir water; that from the Susquehanna River taken at the intake to the pumps, and the water from one of the wells. It will be seen by the table that the reservoir water presents the least evidence of organic pollution; river water next; while the well water is shown to be grossly contaminated. Amounts are given in grains in U. S. gallon.

NOTES AND QUERIES.

DIAGNOSIS OF VAGINITIS.

To the Editor of THE MEDICAL NEWS.

SIR: In your issue of June 13, of the present year, it is stated that at a recent meeting of the Paris Obstetrical and Gynecological Society, Martineau stated a most important fact by which specific could be distinguished from simple vaginitis. "It depends upon this that in the specific form of the disease the pus is always acid, while in the simple it is alkaline." Since the mucus of the vagina is normally acid, would not this fact detract from the value of Martineau's statement? Respectfully,

F. A. BURRALL, M.D.

48 WEST SEVENTEENTH STREET, NEW YORK.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 16 TO JUNE 29, 1885.

PORTER, J. Y., *Captain and Assistant Surgeon.*—Having been found incapacitated for active service by an army retiring board, ordered to proceed to his home and report by letter to the Adjutant-General of the Army.—*S. O. 136, A. G. O.*, June 15, 1885.

HARTSUFF, ALBERT, *Major and Surgeon.*—Assigned to duty at Fort Hamilton, N. Y. H.—*S. O. 133, Department of the East*, June 24, 1885.

MIDDLETON, J. V. D., *Major and Surgeon.*—Granted one month's leave with permission to apply for fifteen days' extension, to take effect about 15th proximo.—*S. O. 88, Department of Missouri*, June 19, 1885.

BROWN, H. E, *Major and Surgeon.*—Assigned to duty as Post Surgeon, Fort Reno, Indian Territory.—*S. O. 91, Department of Missouri*, June 24, 1885.

TAYLOR, BLAIR D, *Captain and Assistant Surgeon.*—Ordered from Department of Texas to Department of the East.—*S. O. 141, A. G. O.*, June 20, 1885.

CARTER, WILLIAM F., *Captain and Assistant Surgeon.*—Ordered from Department of the East to Department of Texas.—*S. O. 141, A. G. O.*, June 20, 1885.

DAVIS, WILLIAM B., *Captain and Assistant Surgeon.*—Leave of absence extended three months.—*S. O. 142, A. G. O.*, June 23, 1885.

EBERT, R. G., *First Lieutenant and Assistant Surgeon.*—Granted leave of absence for one month, to take effect about July 5.—*S. O. 97, Department of Colorado*, June 17, 1885.

ROBERTSON, R. L., *First Lieutenant and Assistant Surgeon.*—Now on leave of absence, directed to report in person by July 7, 1885, to Commanding Officer at Columbus Barracks, Ohio, to accompany detachment of recruits to Department of Texas. On completion of this duty to rejoin his proper station.—*S. O. 143, A. G. O.*, June 24, 1885.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING JUNE 27, 1885.

LONG, W. H., *Surgeon.*—Granted leave of absence for three days, June 18, 1885.

FESSENDEN, C. S. D., *Surgeon.*—Leave of absence extended seven days on account of sickness, June 24, 1885.

WHITE, J. H., *Assistant Surgeon.*—Granted leave of absence for twenty-one days, June 23, 1885.

FOUR CASES OF EXTRAUTERINE PREGNANCY.[1]

BY MATTHEW D. MANN, A.M., M.D.,
PROFESSOR OF OBSTETRICS AND GYNECOLOGY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF BUFFALO; FELLOW OF THE AMERICAN GYNECOLOGICAL SOCIETY.

UNTIL quite recent times extrauterine pregnancy has been considered a very rare and almost irremediable condition.

Parry, by collecting the histories of five hundred cases, first showed how comparatively common it is; but he showed more than that, for by carefully studying the natural history of the disease, if we may call it such, and by comparing this with its pathological anatomy, he pointed out when to suspect its existence, and how to diagnose it. As a natural result, came improved methods of treatment, which, if nôt altogether settled, have done much to make the management of at least a certain class of cases both safe and easy. As regards the treatment of other cases, more experience is needed before definite rules can be formulated.

Let me first place clearly before you the signs and symptoms which experience has shown to be connected with this condition, and on which we can rely in making a diagnosis. In doing this I quote from the writings of others, especially from Thomas, Garrigues, and Parry.

The accident of an extrauterine gestation is met with most commonly in women who have been long sterile, those with a history of previous uterine disease, and in widows and others illegitimately pregnant. As a rule, we have the ordinary symptoms of pregnancy, gastric, mammary, and others. In the diagnosis of the pregnant condition I would attach peculiar importance to the mammary signs, as being, in the majority of cases, among the most reliable, if the pregnancy has advanced far enough. Besides the symptoms of pregnancy we have, as Thomas says: 1. Irregular gushes of blood, sometimes accompanied by portions of membrane—or, as I have myself seen, a complete cast of the uterine decidua, much hypertrophied and thickened. These shreds can generally be distinguished by the aid of the microscope from the decidua of a non-pregnant uterus.

2. Pain, either a fixed, grinding pain in the iliac fossa, or sudden paroxysmal pains of the severest kind, and often accompanied by symptoms of shock, lasting a few hours, and recurring at irregular intervals. These forms of pain are well illustrated in the cases which I shall relate.

3. Symptoms of abortion, without any fœtus; quite rare.

4. In a small proportion of cases there are no premonitory symptoms. The first indication of anything wrong being shock-collapse, and sudden death from rupture of the sac and hemorrhage. Such a case was well illustrated in a report made to the Society a year or more ago by Dr. Clark.

The *physical signs* are commonly, 1. Increased size of the uterus, but not in proportion to the supposed stage of the pregnancy. This increase is held by some to be proportionate to the nearness of the sac to the uterus; in a tubal pregnancy the increase being greater than in the abdominal variety.

2. Evidence of the emptiness of the uterus by the passage of the sound or finger.

3. The presence on either side or behind the uterus of a cystic tumor, generally smooth in outline, somewhat tender and obscurely fluctuating. Ballottement is present in a small proportion of cases.

With these signs and symptoms clearly in mind, we should not find the diagnosis of the condition nearly as difficult as it was formerly thought to be.

I am far from wishing to make light of the difficulties, but I would like to see the profession outside of the specialists more generally recognize the possibility of arriving at a correct conclusion in a majority of such cases,—a conclusion which must give to the woman many more chances for her life.

That the dangers are great is generally recognized, and may be shown from Parry's figures, who found the ratio of mortality to be upwards of 67 per cent. But with the methods now at our command, provided there is an accurate and early diagnosis, these dangers can be almost certainly avoided. In this connection let me quote from Dr. Garrigues's admirable paper.[1] I think, he says: "It is not amiss to point out, if there are difficult cases, there are others in which the diagnosis is very easy, and that certain symptoms are so common in extrauterine pregnancy that they ought to arouse a strong suspicion of its existence, and call for the most careful examination and careful watching of the case. It is painful to read the (by no means rare) histories of cases in which no physical examination was made. The first time the patient is sent home with a prescription for an anodyne for her colic, the next time she is found dying, and the last act in the tragedy is the autopsy revealing a small ruptured fœtal cyst, with internal hemorrhage. It is no less painful to read of an autopsy revealing a cyst measuring from seven to nine inches in diameter, which had not been found, although a vaginal examination had been made."

If you ask for the points of difference between the varieties—tubal, ovarian, and abdominal—I can only say that such a diagnosis is impossible, so far as my limited experience goes. I am inclined to side with Lawson Tait, who believes that all ectopic gestations are in the tubes.

Before discussing the different plans of treatment, I will read to you the histories of four cases which have come under my observation, as they illustrate well both the natural history of the disease and the plans of treatment which are generally advocated, at least, in this country.

CASE I.—September 30, 1882, I was called to a neighboring town to see a patient, of whom I at that time learned the following history: She had been married twelve years, and had had four children. Her first labor was premature, and her last child was born eight years before. She had always enjoyed good health up to the time of her present illness; menstruation had been normal, bowels regular, and all the bodily functions carried on in a perfectly healthy way; was of good constitution. She had last menstruated twelve weeks before, or about the first of June. On the 29th of July, two months before I saw her, she ate a hearty dinner at 12 o'clock; at 1.30 she had a severe paroxysm of pain, so severe that she fainted—to use her own term—"at every relaxation." When consciousness returned she would vomit and purge; a new paroxysm of pain would follow, with fainting, and so on. This condition lasted all the afternoon. Towards evening the intervals between the pains were longer, and during the night the pains, though still severer at every recurrence, were not attended by the other symptoms.

The next day she suffered greatly from nausea ("perhaps caused by the morphine used"), and was unable to move herself in bed in the least because of the lameness in her back and soreness of the bowels. This attack was characterized by a very weak pulse, and all the other symptoms of shock. There was very little elevation of temperature. The pain she defined as being exactly like childbirth pains, only in the bowels. After one terrible pain she declared that something had given way. The next day she was better, but there were great tenderness and soreness just above the symphysis pubis, and a little to the left; and her back felt as if it were "entirely broken in two," so that she could not sit up for five minutes on account of this feeling, when otherwise she would have been very comfortable. She gradually recovered, and was able to get up and move about the house. In two weeks there was another attack, somewhat less severe, but it left her very weak, and she was thenceforth confined to her bed.

She had several attacks at intervals of from six to fourteen days, varying in intensity; but, as she grew weaker, she was unable to recuperate between them. During this time she described, as a peculiarity of her condition, that she would have a natural, healthy appetite, when she felt able to eat anything. Again, for a week she would not be able to retain anything, not even water, on her stomach, and this without any visible change in her condition. She also suffered severely from sleeplessness and restlessness even when there was no pain, and she had never been at all a nervous woman. An examination during this interval—the exact time of which I cannot learn—revealed a tumor to the left of the uterus, rounded, firm, and somewhat tender. This gradually enlarged, and finally became visible above the symphysis. It grew steadily until the 20th of September, when she had a very severe attack of pain, accompanied by severe shock, so that her life was despaired of. The tumor at this time enlarged rapidly, and within a few hours became three or four times its former size. When I saw her the pain had subsided, but she was still very weak, with a feeble, rapid pulse.

There was a firm, circumscribed tumor in the left ovarian region, extending upwards, and nearly to the umbilicus. This was quite firm, though not hard, and did not convey any sense of fluctuation. The tumor could be felt, per vaginam, to the left and behind the uterus. A sound passed into this organ showed it to measure about three inches in length. It seemed to be thickened and somewhat enlarged, but not much softened. The breasts were not much enlarged, though the nipples were somewhat prominent, and the areola darkened; no fluid in them that I remember of. Without much hesitation, from the history and from the result of my examination, I diagnosed the case to be one of extrauterine pregnancy. My idea was that the attacks of pain from which she had suffered had been those usual in extrauterine pregnancy, the cause of which has not yet been satisfactorily explained, and that the last attack had been accompanied by rupture of the cyst. This rupture being probably subperitoneal, and the blood being thus enclosed, the hemorrhage had ceased.

I gave a favorable prognosis, thinking that the child was dead, and that the effused blood would be gradually absorbed, and recovery take place. In order to make sure of the death of the child, I advised that a current of electricity should be passed through the swelling every day for a week. This treatment was carried out, and the prognosis fully justified.

About October 1st there was a slight, bloody discharge from the uterus, the first since June 1st. Four weeks after this she menstruated regularly.

For the first two weeks of her convalescence there was a considerable discharge of whitish mucus from the rectum, not offensive in odor. Her recovery was perfect; though to this present time there is a hard bunch situated above the pelvis, as large, she thinks, as an egg. This she says is somewhat tender and sore around it. She is able to walk two or three miles, and can endure physically as much as she ever could. The diagnosis in a case like this can of course never be fully established; but the physical condition, together with the history of the case, leave little doubt as to its true nature. If not an extrauterine gestation, what was it? Nothing else that I know of would have given these severe recurring attacks of pain with shock. There were also cessation of the menstruation, and enlargement of the uterus; also a gradually enlarging tumor to one side of the uterus. The first attack and the last, which are described as the worst, each occurred, it will be noticed, about the time of a menstrual epoch. One symptom was wanting—the discharge of the decidua—but this is not invariable. The uterus was somewhat enlarged.

The sudden enlargement of the tumor at the last attack can only be accounted for by a hemorrhage confined within some limiting membrane, and this could only have been the peritoneum.

Digitized by Google

Supposing it to have been a tubal pregnancy, rupture of the tube may have taken place between the folds of the broad ligament, and the hemorrhage being thus enclosed within its walls a fatal result from bleeding was prevented. Tubal pregnancy, it is claimed, can go to term though early rupture is certainly the rule. If this be so, it is not too much to suppose that it can go to the fourth month, and as the tube is really thinnest when at the junction of the ligaments, rupture at that spot is not improbable.

CASE II.—This case was seen in consultation with Dr. Briggs, of this city, who has kindly furnished me with the notes.

He was called to see Mrs. R., widow, mother of child, on the 30th of April, 1883. "I found her suffering from more or less severe pain of colicky character, which she said had troubled her very much for some weeks. She stated that she thought she was about three months pregnant, her last menses having been about the first of February. During this time, she had had some irregular slight bloody discharge, and at one time thought there was something like a fleshy membrane in the flow. Her breasts have increased very much in size, and the areola and nipples had darkened. There was no nausea or vomiting, the same having been the case with her previous pregnancy.

"On the fourth of May she again called me (Dr. Briggs), and I found her suffering from very severe pain in the hypogastric region. It was allayed by opium suppositories, etc. During the whole of the following week she had more or less severe pain, and on the 11th, just one week from the previous attack, she had another, even more severe attack. From this time until the 19th she was visited daily; her pain being severe and nearly continuous. The character of the pregnancy being now suspected, Dr. Mann was asked to see the case, but without any intimation being given to him as to its possible character.

"The consultation was held May 19th. Dr. Mann, after a careful examination, emphatically confirmed my idea as to the nature of the difficulty. The examination of the patient at this time showed the breasts much enlarged, tender, and containing a little fluid; nipples protuberant and areola darkened. By bimanual palpation a round smooth tumor could be felt behind and on the left side of the uterus, a sense of obscure fluctuation was discernible but no results were obtained by ballottement. Uterus was pushed a little forward and to the left, and was somewhat enlarged, though not markedly so. The treatment recommended by Dr. Mann was the faradic current.

"On Monday, May 21st, the electric treatment was begun. One pole, the negative, was placed in the vagina, and the other on the tumor on the outside of the abdomen. The current was gradually increased up to the limit of endurance and several times reversed. On the 22d, fœtal motion was distinctly felt by the patient during the treatment. On the 23d this motion, which had been felt at previous examination, had disappeared. On the 26th soreness was gone and pain on direct pressure over the tumor was very much less. On the 28th soreness and pain on pressure were all gone and the patient was dressed and remained up and about her room all day for the first time in weeks. At this time the tumor had diminished very perceptibly in size, and the breasts had become shrunken and flabby. These changes having begun after the first application of the current. On the 2d of June the current was used for the thirteenth and last time. The tumor could now be felt only with great difficulty externally; while an examination per vaginam showed it to be very much smaller and closely attached to the left horn of the uterus. Through the rectum it could be easily mapped out and its relations to the uterus distinctly recognized. The patient now declared herself free from pain and said she felt as well as she ever did. On the 16th she left the city for a western State."

This case, through the courtesy of Dr. Briggs, I saw twice, once before treatment, and once after. When I first saw her, the tumor was as large as a medium sized orange, the last time it was as small as a small hen's egg. From the relations which the tumor held to the uterus at the final examination, I am inclined to consider this also a tubal or a tubo-ovarian pregnancy. That the diagnosis was correct scarce admits of doubt, it was as plain as anything could be. The natural history and the physical conditions were quite classical, and could be explained in no other way. That the treatment was the direct cause of the happy result seems to me to be equally certain.

CASE III.—In September, 1884, Dr. E.V. Stoddard, of Rochester, N. Y., asked my opinion as to the value of electricity in the early stages of extrauterine pregnancy. He stated that he had a case under observation, and was considering the question of treatment. I urged very strongly the advantages of electricity over any other plan, and he promised to use it and report the result. This he has kindly done, and with his permission I add his case to my series. I was, unfortunately, prevented by the state of my health, from going to Rochester to examine her. It will be noticed that it is in many respects a counterpart of my second case.

"Mrs. L., æt 27, general health good, first came under observation about September 20, 1884. She complained of severe attacks of pain in the lower abdomen, and a slight discharge of blood from the vagina, slight tenderness exists over the left ovarian region. Menstruation had been absent during the past two months, but previously was quite regular. Attacks of pain in the uterine region began about three weeks before coming under observation and have been steadily increasing in severity.

"A vaginal examination reveals the uterus apparently normal in size but pushed over to the right side of the pelvis, Occupying the site of the left broad ligament appears an ill-defined tumor as large as a small orange, not firm to the touch, and extending backwards into the pelvis. By bimanual examination the tumor can be very readily recognized, and is clearly the enlarged left Fallopian tube. The patient had never been pregnant. The last coitus occurred early in July, the last menstruation having occurred June 23d.

Digitized by Google

"A careful consideration of the case led to a diagnosis of tubal pregnancy. This opinion was shared by two medical friends with whom the case was seen in consultation. So severe and frequent were the attacks of pain becoming, and slight discharge of blood so constant, that it was feared that rupture of the sac might occur at any time. All preparations were made to do laparotomy at any moment if necessary, but as a previous expedient it was determined to try electricity. By means of an electrode passed into the vagina and carried up to the junction of the enlarged Fallopian tube with the uterus, and a sponge electrode placed externally over the ovary, a rapidly interrupted current from five cells, with a long coil of fine copper wire, was passed through the tumor and continued for ten minutes.

"During the succeeding two days no attack of pain occurred, and the slight hemorrhage also ceased. Two days after the first application, the electricity was repeated, and a third time after an interval of two days from the first application all symptoms ceased. Menstruation came on naturally, the last of October, no pain or unusual symptoms occurring. An examination after this period showed the tumor much reduced in size. Menstruation recurred in four weeks and was normal. The tumor was then found very greatly reduced in size, the only trace being thickening of the Fallopian tube. The pregnancy was evidently terminated by the blighting of the ovum by the first application of the interrupted current."

CASE IV.—This case I saw in consultation with Dr. Deihl, of this city: it differs entirely in its history and results from the other cases. Dr. Diehl has kindly furnished me with the earlier portion of the history.

"Mrs. H., æt 42, one child 18 years of age, no miscarriage. I was first called to see her October 7, on account of excessive bleeding, supposed to be caused by the shock of a serious illness of her husband. This was checked by ergot after two days. I next saw her January 4, 1884, on account of retention of urine. I was obliged to use the catheter until the 12th. In March she was visited at various times, as she was suffering from severe pains in her limbs and bowels accompanied by vomiting. During all this time she menstruated irregularly.

"About April 1st, I saw her again and found a tumor in the left lower portion of the abdominal cavity, which I took to be a cancerous growth; made no vaginal examination as she was so very weak, and I feared hemorrhage. A short time after this I was satisfied I could detect fœtal movements in the tumor, and then considered it a case of extrauterine pregnancy."

About April 10th called Dr. Mann in consultation. He found the tumor extending nearly as high as the umbilicus and entirely to the left of the median line. He easily detected fœtal life and agreed in the diagnosis of extrauterine pregnancy, but as the woman insisted most strongly that she had carried her first child in the same situation, we were in doubt whether it might not be a pregnancy in the left horn of a uterus unicornus or bicornus. For this reason we did not explore the uterine cavity. The woman, then, we calculated, was about five months pregnant. From this time on, she seemed to feel well, having only occasional pain, and was visited about once a week.

On August 1st, Dr. Mann saw her again, as the end of pregnancy was so near that no harm would result if labor should come on, and as the nature of the case was so doubtful we determined to explore the uterine cavity. This we did with the finger and sound, and found it enlarged but empty and normal in development.

As this case was now to far gone to allow of any attempt to kill the child by electricity we determined to await the false labor which usually occurs in such cases, and the subsequent death of the child before operating; my reason for this will be stated later. In August, during my absence from town, Dr. Diehl reports that she had somthing like a labor, and when I saw her in September, there were no signs of fœtal life; we determined, however, to wait a little longer as she was doing moderately well and there seemed to be no pressing need of an operation. In the second week of Semptember, however, she seemed not quite as well and it was evident that the time for action was approaching; but as there were no urgent symptoms we put it off, thinking that the longer we could defer it the better would be her chances, that is, as long as she was doing moderately well. In this we were mistaken.

On the night of the 24th of September, while straining at stool she felt something give way. She had severe pains, and when Dr. Diehl saw her early in the morning she was in a state of collapse. He summoned me at once and I operated at 10 o'clock, A. M., September 25th, assisted by Drs. Diehl, Phelps, Rochester, Bartow, and a number of other gentlemen.

Before the operation the patient was entirely conscious and hopeful, but with a good deal of pain and tenderness in the abdomen, and a very small, weak, and rapid pulse. On getting through the abdominal walls I found the peritoneal cavity filled with a thin purulent fluid, which flowed out in great quantities. As soon as this had in a measure ceased, I opened the cavity freely and sponged out what remained, I then found the fœtal cord extending from a rent in the tumor in front and to the right side. Rapidly enlarging the opening I removed the fœtus, thoroughly washed out the abdominal cavity and sac with hot boracic acid solution, and then stitched the edges of the sac to the abdominal wound. During the operation the patient grew rapidly worse and died just as it was completed.

A post-mortem examination was made the next day by Dr. Peterson, and the whole of the pelvic viscera together with the sac was removed and are now presented for your examination. You see in front the uterus much enlarged, measuring five inches in length, and behind it and closely attached to it a large sac with thick walls (apparently muscular in structure, though no microscopic examination has been made), as large as the uterus at term; attached to the base of this sac is the placenta, this is divided into three separate portions or cotyledon, one much larger than the others. The sac is smooth on the outside and only attached to the in-

Digitized by Google

testine at one point, viz., when it comes in contact with the rectum. Examining the uterus more closely, we see that the decidua is present and thicker than normal. The right Fallopian tube is also to be traced, but the left tube is wanting, and from the thickening of the tissues around the left horn of the uterus, we may certainly suppose that the left tube was the original seat of the impregnated ovum. That the sac is the enlarged and hypertrophied tube is perhaps not susceptible of proof, but appearances certainly point strongly in that direction.

Consideration of Treatment.—The treatment of extrauterine pregnancy must be adapted to the peculiar conditions and circumstances of each case. Unfortunately many of the cases are not seen, or even the existence of the complications suspected, until the alarming symptoms due to rupture of the cyst are developed. When this happens in a patient in whom ectopic gestation was not previously suspected, the difficulties which surround the case are very great. There is little time to think and consider, and to arrive at a carefully made diagnosis. But, if this can be accomplished, the brilliant results achieved by Mr. Lawson Tait in opening the abdomen—four successes out of five cases, must encourage us to follow his example. If the diagnosis is made before rupture takes place and in the first four months, the indications are very plainly to stop the growth of the fœtus by killing it, and thus trust to nature for its removal by absorption. The plans which have been proposed and adopted for accomplishing this result must all be laid aside in view of the safe and easy method offered in the use of a strong current of electricity. The satisfactory results which have followed its adoption in every case must convince even the most sceptical that its trial at least is certainly warranted. Without making any attempt to collect all the reported cases treated in this way I will only mention, besides the three here related, those of Allen, 1; Landis, 3; McBurney, 1; Billington, 1; Reeve, 1: Lusk, 1; B. Emmett, 2; Thomas, 9; Garrigues, 1; Wilson, 1; Haines, 1; Mundé, 1; a total of 25.

There have been no fatal cases in which this treatment alone has been used. Braxton Hicks reported a fatal case, but he combined puncture, and the patient died of hemorrhage.

As to the character of the electricity to be used, both the galvanic, and interrupted and the faradic, have been used with success, but the latter seems to be the favorite. It should be as strong as the patient can bear, and kept up daily until some evidences are obtained that the child is dead.

As to the treatment of those cases which have passed the fourth month, and where the child is still living, opinions still differ. Shall the woman be allowed to go to term, or at least until the twenty-eighth week, when the child becomes viable, and then be operated on? Or shall the child be killed at once and left *in situ*, to be removed as soon as there is an indication? Or shall it be left to die after the completion of the full term of gestation, and then removed?

Attempts to save the life of the child, by removing it after it becomes viable, have generally resulted disastrously to the mother, and almost equally so to the child. Parry reported twenty cases of operation with the child living, with eight children and six mothers saved; but, as Lusk shows, five of these successful cases should be stricken out altogether. Litzmann furnishes nine other cases, all fatal but one; to these we must add one case by Lawson Tait, and one by Netzel, both fatal to the mother. Thus out of twenty-six cases there is only one certain recovery of the mother, and but a small percentage of children saved. Evidently this is not very encouraging. The reason for the bad results is to be found in the difficulty in managing the placenta. Nature's apparatus for stopping up the sinuses, a contracting womb, is wanting. If any attempt be made to disturb the placenta uncontrollable hemorrhage will follow, and this occurs often as well if the placenta is left intact during its elimination. With the death of the fœtus the sinus becomes obliterated, and this danger is removed; so that, when the operation is deferred until the child is dead, the results, as might be expected, are much better. For instance, Litzmann has collected thirty-three cases of operations after the child was dead with only sixteen deaths, or more than 50 per cent. of recoveries.

It was with these figures in my mind that I advocated delay in Dr. Diehl's case. Whether there is not a better way than this remains to be seen. Dr. Garrigues has proposed that the child be killed as soon as the diagnosis is made, no matter what the stage of pregnancy, and the same idea occurred to me after this case and before reading that part of his paper. That it could be done, I have no doubt.[1] I have killed a kitten several months old, by the current from an ordinary faradic battery, in a very few minutes, and I have no doubt a seven or eight months fœtus could be killed in the same way. That the life of the child is not worth considering I have already shown. If we try to save it, the life of the mother will be almost certainly sacrificed and the chances of saving the child are very small.

If we let pregnancy go on and await the death of the fœtus from natural causes we certainly expose the woman to many risks, rupture of the sac may happen at any time and has been observed a number of times at the spurious labor which commonly occurs. Even with the death of the fœtus at term the dangers are not over, suppuration of the cyst and rupture are still to be apprehended and absorption is very little to be expected. In the fifth or sixth months, however, the dangers just mentioned are less and the chances of a favorable termination by natural means are much greater, and, as Garrigues says, "even if the worst should come to the worst and the fœtal sac suppurate, causing septicæmia, there would still be a fair chance of recovery by laparotomy, and at all events an infinitely better chance than by laparotomy performed during the lifetime of the fœtus. The chances will even be better than in those cases in which suppuration (and he might have added rupture) sets in after the

[1] The case of Drs. Duncan and Mason in St. Bartholomew's Hospital Reports 1883, must be thrown out as evidence. The exact time and cause of the death of the fœtus, were evidently unknown.

Digitized by Google

end of gestation, for the smaller the fœtus and its envelopes the less trouble is to be anticipated."

The rule of treatment then which I would deduce, would be—if the fœtus is alive, destroy it at once by electricity, no matter at what stage the pregnancy be. If it is dead and in the earlier months, leave it alone until some clear indications for operation show themselves. In the later months after its death wait four or five weeks and then remove it by laparotomy. The advisability of the latter recommendation might be questioned, but certainly the risks which a woman runs who carries in her abdomen a seven, eight, or nine months extrauterine fœtus are so great that a skilfully performed laparotomy is preferable. The absorption or encysting of a large fœtus, while it may occur, is so unlikely, and the danger of rupture or of septicæmia is so great, that it hardly seems justifiable to allow her to run such a risk. Perhaps my single experience leads me to take too decided a view, but I should directly prefer an early operation to putting it off too long. Unfortunately, we have nothing on which to base a rule as to the exact length of time that we should wait, and the necessary data are obviously very difficult to get.

More experience is necessary before deciding this point, but, as I have already said, my experience and the opinion I now hold would lead me to an early operation rather than to indefinite postponement and the expectant plan.

COCAINE IN THE AVULSION OF INGROWING TOENAILS.

BY F. PEYRE PORCHER, M.D.,
OF CHARLESTON, S. C.

A LADY came to me after undergoing very great suffering all winter from the ingrowing of both toenails. She had been incapacitated for taking exercise; there was loss of sleep, and her health was being undermined.

As it was a condition precedent that there was to be *no pain*, chloroform was promised if required, and I proceeded as follows:

A four per cent. solution of hydrochlorate of cocaine was instilled, drop by drop, from the point of a hypodermatic needle upon the slightly raw surfaces in the furrows on each side of the ingrowing nail of the big toe. A rag, wet with the same, was kept pressed against the upper surface of the toe, and three injections of this strength were made hypodermatically in the flesh at the base of the nail, just above the matrix. The tissues here being thin, and not very cellular in structure, probably ten to fifteen drops may have been received and absorbed.

After the lapse of fifteen minutes the narrow blade of a fine pointed pair of scissors was passed under the nail, which was divided to the matrix, when the two portions of nail were forcibly extracted with strong forceps, and any shreds of nail remaining at the roots were cleared out.

Having remarked that the operation was finished, the lady, who had not winced, expressed great surprise. After three days she was well enough, wearing a light slipper, to visit friends some miles in the country, and three days later returned to her home in one of the upper counties.

I had witnessed a similar operation performed by a gentleman in this city, which was successful.

MEDICAL PROGRESS.

CONCUSSION OF THE SPINAL CORD.—DRS. DUMÉNIL and PETEL, in a clinical and critical study of concussion of the spinal cord, arrived at the following conclusions:

1. The existence of concussions of the spinal cord may be maintained as an established fact.

2. It may be the origin of consecutive inflammatory lesions.

3. Such lesions may present the form of systematic myelitis.

4. Concussion may exist in a latent condition and be only revealed by secondary manifestations, varying from simple transitory congestion to incurable sclerosis. —*Archives de Neurologie*, May, 1885.

FIXATION OF A FLOATING KIDNEY.—PROFESSOR F. FRANZALINI, on May 4, 1885, operated upon a young woman for the fixation of a floating kidney. An exploratory abdominal incision was made, a tumor of the mesentery being suspected. The true nature of the tumor being thus disclosed, Professor Franzalini operated on the displaced kidney according to the method proposed by Rose, namely, by fixing it to the lumbar wall by two catgut sutures passing through both capsule and parenchyma of the organ. The exploratory incision united by first intention, and the woman recovered without an unfavorable symptom.

The two operations—laparotomy and fixation of the kidney—occupied only one hour and a half.—*Gazzetta Medica di Torino*, May 15 and 25, 1885.

TREATMENT OF NERVO-PULMONARY AND CARDIAC ASTHMA BY PYRIDINE.—M. GERMAIN SÉE, at a meeting of the Académie des Sciences, held June 2, 1885, summarized his treatment of nervo-pulmonary and cardiac asthma, as follows:

1. Whatever the form of the asthma, whether it be nervous, emphysematous, or catarrhal, or of gouty origin, the treatment by iodine constitutes the truly curative method. When iodism occurs the employment of pyridine will be found useful, and may be considered a certain means of curing the attack. This remedy is the best palliative, though iodine is the efficacious remedy, in the treatment of the disease.

2. Pyridine is superior in the effects produced to the hypodermatic injection of morphine; its action more permanent and less offensive.

3. In simple nervo-pulmonary asthma the attacks may be altogether suspended. In asthma complicated with serious pulmonary lesions, the treatment should exceed eight or ten days in order to obtain permanent amelioration.

In cardiac asthma, with or without renal and dropsical complications, pyridine is of great service in combating the continual or paroxysmal oppression which accompanies the disease.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, June 5, 1885.

PORRO'S OPERATION.—DR. FIBBI ANTONIO, on the 15th of April, 1885, performed Porro's operation successfully on a primipara. The patient was a woman aged 32 years, and the operation was not necessitated by the existence of any pelvic deformity, but on account of the presence of a large tumor which absolutely prevented the passage of the child. The patient had been in labor four days, and the water had broken three days previous to the operation, which was performed in a little more than one hour. The peduncle was treated by the extraperitoneal method. The patient survived one day only, and died in collapse.—*Gazzetta Medica di Torino*, May 15, 1885.

REMOVAL OF A FIBRO-ENCHONDROMA OF THE RIGHT TONSIL.—PROF. BOTTINI reports the removal of a fibro-enchondroma from the right tonsil. The patient, a woman, aged thirty-three years, during the last three years noticed a progressive enlargement of a growth upon the right tonsil. This at last attained such dimensions that it produced deafness and tinnitus in the right ear, and also seriously interfered with deglutition and respiration.

The patient had sought in vain to obtain relief, and finally came under the notice of Dr. Bottini, who diagnosticated the tumor as above, and undertook to relieve her by operation. The tumor was removed in fragments, partly with the bistoury and partly by the fingers, after an incision had been made in the right anterior palatine arch without serious hemorrhage, though the operator held himself in readiness to ligate the carotid artery in case of necessity. The patient was at once relieved of the symptoms referred to and recovered without interruption. Microscopic examination confirmed the diagnosis previously made.—*Gazzetta degli Ospitali*, No. 12, 1885.

EXPERIMENTAL STUDY UPON ENGRAFTED BONE.—DR. EDUARDO SALVIA, in the *Gazzetta degli Ospitali*, of May 13, 1885, gives the following *résumé* of his experiments upon the engrafting of bone:

1. The engrafting of a small fragment of bone between the two fragments of a long bone, in which a portion of the shaft is lost, is possible *even in individuals of different species*. This fact is demonstrated in an experiment in which one of a number of engrafted portions of bone contracted adhesions with the adjoining tissues and continued to live, notwithstanding the displacement to which it was subject on account of muscular action.

Their diminution could not be attributed to a tendency to disappear by gradual reabsorption, because if the great abundance of young cells in the osteoid tissue were insufficient to establish the evolutionary condition of the engrafted bone, the extended zone of cartilaginous tissue which surrounded the osseous nucleus, which united with it, and which on the periphery was in relation with a connective tissue rich in cells, excludes every doubt that the disappearance of the fragments of the engrafted bone was the effect of its gradual absorption, and that after some days it would entirely have disappeared.

2. It is not necessary that the portion of bone engrafted be supplied with periosteum; as likewise it is not absolutely required that the fragment be transplanted immediately after having been removed from the living body; because the vitality of the osseous tissue is preserved through several hours after it has been removed from the ordinary conditions of life (blood supply and innervation), and notwithstanding it is subject to the mechanical interference and to conditions little favorable to life.

3. The stage of evolution of the fragments of engrafted bone is preceded by a phase of involution, in which the osseous tissue loses its calcareous constituents, and returns to the state of osteoid tissue; and as such, after its organic relations with the surrounding tissues are well established, proliferates and develops, and then commences anew the deposit of the calcareous salts in the centre of its growth.

4. The growth and formation of the new bone take place by a process the same as is observed in the epiphysial cartilage of the long bones.

THE ABORTIVE TREATMENT OF TYPHOID FEVER WITH NAPHTHALIN.—L. GÖTZE, in *Zeitschr. für Klin. Med.*, 1885, No. 1, reports the use of naphthalin in a local epidemic of typhoid fever. Thirty-five cases in all were treated with the following results. With the exception of three cases treated with the drug, enlargement of the spleen was not noticed. The remedy was administered in doses of 15 grains, and 75, 90, and even 105 grains daily were received by the patients. Other remedies were substantially not administered.

The naphthalin employed was that directed by Rossback, the purest resublimated with the oil of bergamot. During the course of the disease all the patients received over 1050 grains, and many of them 2100 grains.

Untoward effects (with one exception, in which naphthalin intoxication was exhibited chiefly in the form of brain depression, which was readily relieved by soda sulphurata, were not observed.

The course of the disease, on the whole, was exceptionally favorable, and the intestinal symptoms—diarrhœa, pain in the cœcal region—was favorably influenced. In three cases the disease appeared to be generally shortened by the drug.

Other cases through its use became abortive in from six to ten days; in some others the fever did not continue more than sixteen days. In a final series of cases the process of the disease was not shortened, but the period during which marked elevation of temperature was maintained was curtailed. Three cases died from serious complications.

In cases in which antipyrin in apyretic doses failed to reduce the temperature, naphthalin produced such effect, as was proven by several trials always with the same result.—*Centralblatt für Klin. Med.*, May 30, 1885.

THE VITALITY OF THE CHOLERA BACILLUS AND THE MEANS FOR ITS DESTRUCTION.—The majority of physicians at the present time believing, as they do, that cholera owes its existence to some minute organism, and that of Koch being the one to which the probabilities most strongly point as the cause of the disease, it is important to know as much as possible of its life history.

Dr. Koch has himself shown that moisture is a prime necessity for the life of the germ, and that it soon

Digitized by Google

perishes in its absence. By the use of well-known disinfectants he has been able to carry out an extensive series of cultures without producing the disease in any of them, with perhaps a single exception.

Drs. Nicati and Rietsch in their investigations have found that in some cases of cholera that the bacillus disappeared four days after the attack, and in the majority of cases they had disappeared on the sixth day; in two cases only were the bacilli found on the eleventh day. When cholera stools or portions of the intestine are placed in a warm, moist chamber, the disappearance of the cholera bacillus follows soon after the development of well-marked putrefaction. In moist earth the cholera bacillus retained its vitality from fourteen to sixteen days. These observers have never seen anything that looked like spores, nor have they been able to confirm the observations of Dr. Ferrán.

The cholera bacillus can be destroyed by many substances, as hydrochloric, nitric, and sulphuric acids, in the proportion of 1 to 2000 of water.

They suggest as one of the best means of insuring the destruction of the germs in drinking water, where boiling is undesirable, to add tartaric acid in the proportion of thirty grains to the quart, and after an interval of an hour to neutralize the acid by a corresponding quantity of bicarbonate of soda, which will make an effervescing drink. Drying the germs kills them rapidly. Simple exposure to dry, warm air for a few hours destroys their vitality. Heating the fluid in which they are contained to a temperature of 140° F. kills them as it does almost all bacteria, and simple boiling is, therefore, the most effectual means of disinfecting soiled clothing or bedding, or of insuring the harmlessness of drinking water.

The practical conclusions to be drawn from these experiments are numerous and important, if we admit the probability that the bacillus upon which Drs. Nicati and Rietsch experimented is the cause of cholera.

The danger of earth moistened with cholera excreta, or of water contaminated with them, is very evident, and the simplicity of the means of destroying the vitality of the germ—*i. e.*, by drying, boiling, or acids—is very satisfactory.—*The Sanitary Engineer*, June 25, 1885.

INOCULATION EXPERIMENTS IN CHOLERA.—MM. NICATI and RIETSCH conclude the detailed account of experimental inoculation with the fluids of cholera patients with the following remarks and conclusions:

We have undeniably obtained in our experimental inoculations symptoms and lesions similar to those of cholera. That is, after a period of incubation, which sometimes occupied three days, and which was sometimes accompanied by cyanosis, there were manifested prostration, algidity, spasmodic muscular contraction, and death, after some hours. Post-mortem examination showed an enteritis, epithelial and rich in rod bacteria, vacuity of the urinary bladder, and repletion of the gall-bladder.

The experimenters conclude, in reference to their inoculation experiments:

1. That the Indian pig is susceptible of inoculation, *per stomachum*, and more certainly by injection into the duodenal ampulla.

2. That the dog may be inoculated by injection into the biliary duct.

3. That the matter capable of producing inoculation is only such as contain the rod bacilli, whether it be the intestinal discharges or bile.

4. The blood of choleraic patients injected beneath the skin and into the veins rapidly produces the effects of a poison. In one instance of intravenous injection an animal was seen to die three days after the experiment. The question whether the blood may be a carrier of the infection is still held under consideration.—*Revue de Médecine*, July, 1885.

ABSCESS OF THE ABDOMINAL WALL CONTAINING THE RIB OF A RABBIT. CURE WITHOUT STERCORACEOUS FISTULA.—DR. JAGOT reports the case of a man aged forty-one years, who consulted him April, 1885, for an inflammatory swelling above the fold of the groin, situated transversely, and open at either extremity with a fungoid fistula. On the same side was an inguinal hernia, and at first sight the abscess seemed to be the result of improper support to this.

The patient related that two years previously he was suddenly, while working, seized with violent pain in the abdomen. Vomiting followed, and for several months he was confined to bed until the formation of the present abscess, which was opened by his attending physician. Since that time the abscess had never healed and was always painful when any unusual effort was made. Examination was made with a probe and a foreign body discovered, whose presence was further confirmed by the introduction of a channelled sound. Manual examination was then made and a body felt, firm in outline, long, and whose centre seemed to coincide with the superior and external fistula. Forceps were introduced at this point and a bone in two fragments was removed. It was slender and smooth and the ends very pointed, proving to be the rib of a rabbit, and was two and a half inches in length. The case is extremely interesting from the fact that after perforation, the bowel spontaneously healed without the formation of an intestinal fistula, nothing but pus having ever discharged from the abdominal opening.—*Le Progrès Médical*, June 13, 1885.

A SPECIES OF ARTIFICIAL ANÆSTHESIA WITHOUT SLEEP AND WITH PERFECT CONSERVATION OF INTELLIGENCE, OF VOLUNTARY MOVEMENT, OF SENSE, AND OF SENSIBILITY.—At a recent meeting of the Académie des Sciences, DR. BROWN-SÉQUARD confirmed the announcement made by him in 1882, of the possibility of producing anæsthesia by irritation of the mucous membrane of the larynx. By this means sensibility to pain more or less completely disappeared in all parts of the body. He then showed that this phenomenon is the result of the inhibitory influence of the superior laryngeal nerves upon the nerve centres, and that it is possible at will to limit the effect so produced, entirely, or nearly so, to one side of the body.

At the meeting referred to, results of new experiments were communicated, and the report confirmed that, by irritation of the laryngeal mucous membrane, sensibility to pain disappears through a number of hours, in man as in animals, while the intelligence, sense, and voluntary movements are in no wise interfered with.—*Gazette Hebdomadaire de Méd. et de Chirurgie*, June 5, 1885.

PHILADELPHIA.

SATURDAY, JULY 11, 1885.

THE MEDICAL CONGRESS MUDDLE.

THE *Journal of the American Medical Association* of last week contains a copy of an opinion by Hon. Samuel J. Randall, late Speaker of the House of Representatives, and a recognized authority on Parliamentary law, as to the power of the American Medical Association to set aside the action of the Original Committee of Organization of the International Medical Congress. It was in deference to this opinion that the Original Committee of eight decided that such of its members as could do so should meet with the new Committee organized by the Association at New Orleans, and present the reasons for the plan of organization which had been published.

In reference to this opinion of Mr. Randall, it may be well to bear in mind that there are many things which a parliamentary body may have the power to do which it is by no means right or proper that it should do. A State may have the power to repudiate its just debts, but the possession of such power is no excuse for exercising it. The American Medical Association may have the power to refuse to abide by the terms of the invitation which it had agreed should be given in the name of the medical profession of the country—it may have the power to repudiate the obligations which its duly authorized Committee publicly incurred, but such power will not excuse it for the unjust and discourteous action which it has taken.

There can be no question that the Committee of eight had full and specific authority to add to its membership, and that the original Committee thus enlarged was authorized to make all arrangements for the Congress, so far as the American Medical Association could give such authority. The International Medical Congress accepted the invitation with this understanding, and thereby practically accepted the original Committee of eight as its Committee of Organization.

The arrangements made by this Committee have been pronounced satisfactory by the leading members of the Executive Committee of the Congress in Europe. Under these circumstances it becomes the duty of the leading members of the profession in this country to signify their disapproval of the changes which have been made, and to refuse to become parties to offering such grave discourtesy to the Congress and to the prominent physicians of this country, who have been thus improperly, and in an offensive manner, set aside.

Already the profession of Philadelphia, Boston, and Baltimore, have declined to be a party to the work of the new Committee. In taking this grave stand they believe that they are acting not against the American Medical Association, but, on the contrary, that they are really stepping in and using their influence to protect it from the results of the damaging action of a small minority, who, for the advancement of their own ends, captured the New Orleans meeting —which was small in number, and not representative of the entire profession, and was easily manipulated— and turned aside the Association from its legitimate work, to array it not only against its own best interests, but also against the vast majority of the profession of America, which, by the action of its new Committee, have been excluded from the Congress.

The injection of the Code controversy into the organization is a flagrant discourtesy to the Congress, because one of its cardinal rules is not to have anything to do with matters relating to medical politics, and it was adroitly introduced at New Orleans as an attractive rallying cry with which to capture the Association. That the Code controversy has nothing to do with the Congress is clearly shown by the unanimous action of the profession in Philadelphia, where the old Code was originally framed, and by the fact that the names of its consistent and strongest supporters are to be found in the list of men who decline to coöperate with the new Committee. In taking this action, they felt that local differences must not be intruded upon an International Congress where they have no place.

A cardinal source of dissatisfaction with the new organization is that it is under the control of a handful of discontented men, who were not included in the preliminary organization, and who stirred up this trouble for what they could make out of it. They

Digitized by Google

used the American Medical Association to this end, regardless of the injury thereby inflicted upon it, and now that they find that the profession has risen in its indignation and repudiates them, they are expressing a willingness to compromise and to make concessions to save their own official heads. But the profession is more than disgusted at the manner in which they have juggled themselves into office, and it realizes the discredit which their doings have brought upon it, and no change of front now can save them from just condemnation. They have committed a great wrong not only against the American Medical Association, but against the profession at large, and the action just taken means, in plain language, that the profession has no confidence in them, and will give no support to any organization of which they are the head.

SYPHILIS AS A CAUSE OF ABORTION AND OF PREMATURE LABOR.

IN a discussion, at the Paris Academy of Medicine, upon the diminution of increase of population in France, some very important statements were made by FOURNIER, which are reported in a recent number of the *Annales de Dermatologie et de Syphiligraphie.*

In the healthy wives of two hundred men who had been treated for syphilis, and in whom the disease had been apparently cured, but was really latent, there were four hundred and three pregnancies, two hundred and eighty-eight living children were born, and one hundred and fifteen dead. This shows that children of a syphilitic father and of a sound mother die in the proportion of one in four. But the pernicious influence is much greater when it comes from the mother, or from both parents. Thus a syphilitic woman married to a syphilitic or to a healthy man, is liable to repeated abortions—in one case eleven were observed, and then a syphilitic child was born. If syphilis be recent in a pregnant woman, her child is almost inevitably doomed to death; she miscarries, or is delivered either prematurely or at term, and the infant soon dies. Fournier states that in forty-four married women who were private patients, and who conceived while affected with recent syphilis—some of them received simultaneously from their husband both child and syphilis—forty-three dead children were born, and only one living one.

But in general the mortality is not so great, though still frightful. Thus one hundred syphilitic wives, almost all infected by their husbands, had two hundred and eight pregnancies, and sixty children survived, while in one hundred and forty-eight cases miscarriage occurred, or premature labor, the children being stillborn, or dying shortly after birth from causes which could be rationally imputed to syphilis. These figures show a mortality of seventy-one per cent., which is to be attributed to syphilis. These statistics are from private practice, while those from hospital observations make this mortality eighty-six per cent.

Syphilis is thus justly regarded by Fournier as one of the most important factors in the depopulation of France. Among the means which he urges to lessen the activity of this cause is the prevention of the early marriage of a syphilitic, and he lays down the rule, that such a person should not marry for a period of from three to four years, during which appropriate therapeutic treatment is pursued.

When Dr. Noeggerath, a few years ago, read, before the American Gynecological Society, his paper upon latent gonorrhœa, especially as a cause of sterility in the female, Dr. Barker stated that, if the views expressed in it were true, a modification of the paper ought to be in every Sunday school library in the land. While a similar suggestion is not made in regard to Fournier's facts, it certainly is a question whether society ought not take some steps to prevent the too early marriage of syphilitics—whether, indeed, the law might not wisely and justly interfere to protect the health of innocent women, and to guard against fœticide and child murder.

Even if legal enactments are impossible, it may be a question for wise and thoughtful parents to consider whether the young man who seeks the hand of their daughter in marriage is free from venereal disease. The majority of parents probably think more of his social position and his wealth than of his freedom from physical taint, and in some cases learn their error too late.

Certainly the physician can do much to prevent the marriage of a syphilitic man until he has been quarantined at least for the period which Fournier suggests. But whether he should make any communication directly or indirectly to the other party concerned is an open question; ought he not, knowing the condition of the intended groom, and being the family physician to the intended bride, in some way let her know the peril she incurs? But, then, the moral question recurs as to his right to make known that which he may have learned mediately or immediately as a professional secret. In most instances, however, love is blind, and his words of warning, if uttered, would be as idle wind.

A PLEA FOR NOISELESS STREET-PAVEMENTS.

MUCH has been written upon the subject of street-pavements from a sanitary standpoint. Invention has been busy, and costly experiments have been tried to determine the best substitute for the ordinary cobble pavement, which is an abomination of American cities, and it would appear that we are coming nearer to a solution of the problem than ever before.

Digitized by Google

The principal qualities which a city pavement should possess are durability, impermeability, smoothness of surface, and noiselessness. When the kyanized-wood pavement was first introduced, it was supposed that a desideratum for a long time contemplated had been supplied, but its speedy decay soon demonstrated its unfitness, and it has been almost entirely discarded in this country. The "composition" pavement was at one time popular, but the material in its construction proved to be unsuitable to resist the wear and tear of even ordinary traffic. MacAdamized roadways are objectionable on account of dust and mud, and the expense of constant repairs. Asphalt blocks have been tried, but they do not appear to be sufficiently durable to withstand heavy traffic, though excellent in small streets, or where the travel is light. The pavements which experience has proved to be most suitable, and which meet the varied requirements of a city, are the granite-block pavements, with even surface and pitched joints, laid on a solid foundation, and the true asphalt pavement laid on a firm bed of concrete; the former being best adapted for the great thoroughfares; the latter for those portions of the city where residences are found and where traffic is light.

The asphalt pavement, by reason of its durability, imperviousness, seamlessness, and smoothness of surface, commends itself to popular favor. Not only is it a pleasure to ride over such a pavement, but it affords an immense saving in wear and tear to both vehicles and animals.

There is one feature of the asphalt pavement, however, to which we desire to call particular attention, and that is its noiselessness, and on this account it is to be preferred where traffic is not too heavy and severe. The incessant clatter and din of horses and vehicles passing over streets, as ordinarily paved, are very trying to many persons. To those nervously constituted or of delicate sensibilities, this form of noise causes great annoyance and is wearing upon the health. To the sick, it is painful in the extreme. The tan-covered street is too frequently the evidence that endurance has been overstepped, and that relief must be purchased at whatever expense. The incessant rattling of vehicles over the rough stony surfaces is bad enough in the daytime, but, when prolonged into the hours commonly allotted to rest it interferes with healthful sleep. The constant noise by day and the interruption of sleep by night annoy the nervous system and tend to render it morbid. Habit goes a great way in obtunding sensibilities, but the effort required to accustom one's self to submit calmly to annoyances often costs dearly. According to an old proverb, we are to endure willingly what we cannot avoid. But there is no sufficient reason why we should submit to a nuisance which has no right to exist and which could be entirely avoided by a little good management.

Now that it has been demonstrated that street surfaces can be paved in such a manner as to be nearly noiseless, and that other qualities of essential importance need not be sacrificed to this prominent idea, let us demand such improved pavements for the sake of comfort and health. The quiet of the Sabbath, in contrast with the never-ceasing din of the week-day, is welcomed for the respite it affords from the incessant noises which tease and exhaust the nervous system. Such quiet, or an approach thereto, it is possible to enjoy upon every day in the week, and it would be of inestimable advantage to the comfort and health of the people. Let us then, by all means, have noiseless pavements.

THE RADICAL CURE OF HERNIA.

IN the modern, or direct, operation for the radical cure of hernia, which consists of ligation of the neck of the sac, with excision of its fundus, and suturing the pillars of the ring, the proportion of failures to the cures amounts, if we mistake not, to about 23.5 per cent., the relapses being due to the weakness of the cicatrix in the serous membrane, which is unable to resist the wave-like impulse of the intestines. As ordinarily performed, the defective point in the operation appears to be the ineffectual sealing up of the entrance of the sac, and MR. BALL, of Dublin, in a paper published in the *British Medical Journal* for September 6, 1884, suggests that a more complete closure could be secured by twisting the sac, tying its neck with an antiseptic ligature, and preventing untwisting by carrying the intercolumnar sutures through the sac. As we have seen no further report of the progress of his cases, we are unable to say what amount of permanent success he has attained.

In the *Medical Chronicle* for June, 1885, MR. JAMES HARDIE, of Manchester, describes a modification of the usual procedure, through which a more abundant inflammatory exudation, with a correspondingly firm cicatrix, and a more effective barrier to the future descent of the hernia are obtained. The sac having been opened, the ligature is carried not only around its neck, but around the transversalis fascia as well, thereby including in the thread a considerable thickness of tissue. The sac itself is not dissected out, but in suturing the pillars of the ring the needle is carried through the subjacent portion of the sac, by which manœuvre the sutures have a better hold, and all of the parts become incorporated into a firmer cicatrix. Unfortunately, a sufficient time had not elapsed in the seventeen cases in which it had been practised to determine the real value of the operation as a curative measure.

In a paper contributed to the same issue of the Journal mentioned in the preceding paragraph, MR.

Digitized by Google

SOUTHAM, of Manchester, calls attention to utilizing the omentum in the radical cure of scrotal hernia. After reducing the bowel in the usual way, the sac, still containing the omentum, is separated from the surrounding tissues as far up as its neck. The neck of the sac and omentum are then transfixed together by a needle armed with a strong double catgut ligature, and tied in two halves, after which the sac and omentum beyond the point of ligature are cut away. In this way the crural canal is left plugged with a mass of omentum, which acts as a barrier to redescent of the gut.

As in the operation of Hardie, sufficient time had not elapsed to test the real merits of Southam's method; but as both procedures would appear to be great improvements over the ordinary direct method, we trust that they will be subjected to an extended trial.

POLLUTION OF OUR RIVERS.

BEFORE the adjournment of the Legislature of Pennsylvania, an act was passed creating a State Board of Health, which has since become a law by the signature of the Governor. The appointments have already been made, and the Board has just organized. We would suggest as a subject demanding the early consideration of the Board, the pollution of the rivers of the State, in order that the necessary data may be obtained upon which to base a recommendation for future legislation. It is a well-known fact that a number of rivers and streams from which potable water is obtained for supplying cities and towns are grossly contaminated by sewage. These places are without the power to suppress the nuisance for want of jurisdiction, and they are not in a position to remonstrate against the act of pollution, since they are, in most cases, guilty of the same objectionable practice. A report upon the subject furnishing the results of a careful investigation and the progress of legislation in other States, and in other countries, with such suggestions as are applicable to our own State, will go far toward establishing an enlightened understanding of the question, and toward preparing the way for subsequent legislation.

SOCIETY PROCEEDINGS.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Seventh Annual Congress held at Detroit, Michigan, June 24, 25, and 26, 1885.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, JUNE 24TH.—FIRST DAY.

THE seventh annual meeting of the American Laryngological Association was opened on Wednesday morning, June 24th, by an *Address of Welcome* from DR. INGLIS, President of the Medical Library and Journal Association of Detroit. An address of welcome was also delivered by DR. SHURLY, of Detroit, President of the Association.

The first paper of the Congress, also by DR. SHURLY, was on

THE USE OF GALVANISM IN CHRONIC DISEASES OF THE PHARYNX.

In this he stated that at the congress of 1880 he had called attention to the use of galvanism in pharyngitis sicca, since when he had used galvanism in a number of cases with good results. The difficulties attending the use of electrodes in the pharynx could be reduced through the use of cocaine, making this plan of treatment of general practicability. He believed that certain conditions of the pharynx, such as chronic engorgement, hypersecretion, etc., are often only local expressions of a derangement of the stomach, the intestinal canal, or possibly some more remote organ. Certain neuroses of the pharynx, such as hyperæsthesia, spasm, also paræsthesia, are dependent upon derangement either of these same organs or of the genito-urinary or mental apparatus, all of which require little or no local treatment. There are certain organic lesions also, of the pharyngeal mucous membrane, which are characterized by glandular hypertrophy, general hyperplasia, hypersecretion, atrophy with diminished secretion, etc. To these he wished to call special attention. They constitute changes which are trophic, and are distinct local disorders.

He believed that glandular hypertrophy and atrophy, with or without persistent extra secretion, and with little organic change in the membrane, were due to a perversion of function of the nervous apparatus distributed through the pharyngeal region. Mere mechanical effect of infiltration or interstitial deposit could not account altogether for the waste of the membrane. It seemed impossible too that the symptoms of typical pharyngeal disease could be fairly attributed to ordinary inflammation and its consequences. Some of these conditions were probably distinct local diseases having for their origin some nutritive abnormality antecedent to the inflammatory changes; perhaps due to metabolic derangement through a disordered trophic function of the hypoglossal, pneumogastric, or sympathetic nerve. Acting upon this theory, he had employed different agents for local use, and of these had gained more lasting effect from galvanism. The mucous membrane having remained in many cases of a vivid color and bathed in a fluid secretion several hours after the application, and in case of atrophy leaving an exhilarating sensation of heat and pliability.

In the severer forms of chronic nasal catarrh, in cases of engorgement with hypersecretion, and also in distinctly neurotic conditions, such as paræsthesia, he had had good effects from galvanism. The following method was advised: First, cleanse the membrane with some appropriate solution, then apply a four per cent. solution of cocaine, and in about five minutes apply the electrodes (which were then exhibited), one through the nasal passage and the other to the posterior and lateral wall of the pharynx, moving them rapidly but gently over the surface and keeping them closely applied. He generally began with two cells, increasing to four or five, of a battery composed of the improved Leclanché

Digitized by Google

cells. The electrodes are naked, unless one is to be applied to the side of the neck, when that is covered. The application should be repeated two or three times a week, although in some cases one thorough treatment a week is enough. This method will not restore already destroyed tissue, but it will arrest those metamorphoses which finally result in either the loss of glandular as well as other elements of the membrane, or the substitution of adventitious for the normal tissues. The time required for permanent results will vary with the case and the state of chronicity presented. The only therapeutic theory was the restoration of the nutrition and normal secretion of the parts by the direct application of the electric fluid to the terminal nerve filaments.

DR. F. H. HOOPER, of Boston, next read a paper entitled

THE RESPIRATORY FUNCTION OF THE HUMAN LARYNX

from experimental studies in the Physiciological Laboratory of Harvard University. He doubted the accuracy of the theory which been advanced by many writers that there is a proclivity of the abductor fibres of the recurrent laryngeal nerve to become affected by disease earlier than the adductor fibres, and his paper was an inquiry into the truth of this problem solely from an anatomical, physiological, and experimental standpoint. The sources from which nervous impulses for the larynx could be received and the channels through which they might be transmitted were minutely reviewed, and the conclusion was reached that the respiratory or abductor nerve filaments contained in the recurrent laryngeal are derived from a greater variety of sources than the phonatory or adductor fibres. The respiratory muscles of the larynx are physiologically more important than the other intrinsic laryngeal muscles, and their extensive nerve supply, the reader claimed, is to protect them from disease, not to open up new channels by which harm may come to them. The experiments were performed on dogs and on one occasion a horse. The dogs were so arranged that the vocal bands could be watched through the mouth while the recurrent nerves were stimulated. It is a familiar fact that under normal conditions any irritation applied to one or both of the recurrent nerves produces a sudden closure of the glottis. The experiments were made on dogs, first, in a state of profound narcosis; second, by irritating the recurrent nerve while it was being slowly destroyed by crystals of chromic acid placed upon it; third, after a thread had been passed through the nerve and retained there many days in order to excite inflammatory changes.

He found that when a dog is profoundly etherized, the action of the constrictor muscles of the glottis is completely abolished. Under these circumstances any stimulation applied to the recurrent nerves produces a forcible dilatation of the glottis instead of the familiar closure. The experiment with chromic acid did not show that there is a proclivity of the abductor fibres to succumb earlier than any others. In one experiment in which a thread had been inserted in the recurrent nerve and kept there a week, it produced some alteration of the nerve fibres, so that when a nerve was irritated below this point the vocal band was abducted, showing that the abductor fibres had lost their power to respond to stimulation. The conclusions were as follows: The principal fact demonstrated is the power and endurance of the posterior cricoarytenoid muscles and of the nerves which supply them. The theoretical reasons are, first, the physiological importance of these muscles; second, their belonging to organic life; third, their extensive nerve supply, all of which tend to preserve their functional integrity. Moreover, if it be true that there is a "proclivity" of the abductor fibres to become diseased, and that unilateral paralysis of the abductor muscle is such a common and harmless lesion, can we not expect theoretically that bilateral paralysis of this muscle will occur more frequently? Yet there can be no dispute whatever that bilateral paralysis of the posterior cricoarytenoids is a disease as rare as it is grave.

Now, with regard to these muscles being *extensors* and like the extensors in other parts of the body, the forearm for instance, more liable to succumb to disease than the flexors, he would ask this simple question: Why should the terms extension and flexion be applied to the rotation of the arytenoid cartilages? The principal office of the posterior arytenoids is to maintain the respiratory patency of the glottis. From the beginning to the end of life they are in a state of semicontraction. They come, therefore, just as near being flexors as extensors, but as a matter of fact are neither the one nor the other in the ordinary acceptation of these terms as applied to the muscles of the general system. They are *respiratory* muscles carrying on a special function. One may as well speak of the movement of the pupil as extension and flexion, or compare the diastole of the heart to the extensors of the forearm or its systole to the bending of the toe. Muscles are analogous, as they discharge analogous function. We recognize no more analogy between the posterior crico-arytenoid muscles of the larynx and the extensor communis digitorum of the forearm than there is between respiration and prehension. If it is desired to seek muscles that are analogous, other respiratory muscles should be examined and the influence of disease upon them noted. In diffused progressive diseases of the nervo-muscular system it is known that of all muscles except the heart itself those belonging to the respiratory system are always the last to be attacked, and there is no valid reason why the respiratory muscles of the larynx, either one or both, should offer an exception to the rule, especially as they are the most important of all. The writer proposed to investigate this subject from a clinical aspect at some future date when perhaps the positions which immobile vocal bands assume may be sufficiently explained without attributing to a wise and conservative nature a proclivity to attack one of the most vital muscles of the human system.

DR. J. SOLIS-COHEN, of Philadelphia, considered it a great honor to the American Laryngological Association to have had this valuable paper brought before it, and believed it would be historical. These experiments would be subjected to criticism, and their verification would become a matter of history in the controversy now existing as to the peculiarity of these abductor fibres to become diseased sooner than the adductors. The dogmatism with which the assertion had been made seemed to have almost paralyzed laryngolicists. For, with the exception of himself, he hardly knew anyone who had ventured a word against it. Even when he had presented a clinical case opposing the theory,

Digitized by Google

and had shown a picture of a larynx, it had been simply in deference to himself that much had not been said against it. The only word of commendation he had received was from Dr. Krause, of Berlin, who had stated that he believed the observation was correct, but attributed the lesion to a different cause. He had had no experience in the physiological experiments made by Dr. Hooper, but there was a point which the latter mentioned which had received clinical support. It was with reference to the facial nerve in sending the respiratory forces to the pharyngeal. In the case of a child suffering from diphtheria with great dyspnœa, he declined to perform tracheotomy because the child was under two years of age. Knowing the great effect of cold on the facial nerve in stimulating the facial centres he placed iced cloths all over the lower part of the neck and jaw. Whenever the iced cloth was applied an inspiration took place. By repeating this frequently the child's life was saved. The phenomena in stimulating one recurrent so that its vocal band passes beyond the median line as in phonation, was confirmatory of some of Krause's experiments.

DR. HARRISON ALLEN, of Philadelphia, said the analogy between constriction and adduction and between dilatation and abduction was, in his judgment, tenable.

DR. E. FLETCHER INGALS, of Chicago, said that in support of the paper in a clinical way he had recently had a case similar to the one related by Dr. Cohen, excepting as to the origin.

DR. DELAVAN, of New York, desired to unite his congratulations with those of Dr. Cohen upon Dr. Hooper's paper. Reference had been made in the paper to a motor centre for the human larynx. Since publishing his own paper on this subject several important contributions had appeared which tended still further to establish the fact of the existence of such a centre, and he hoped that sufficient clinical evidence would soon be accumulated to place the matter beyond a doubt.

DR. HOOPER, in closing, stated that he had only attempted in his paper to study the subject on general physiological and experimental grounds. Clinically it seems a difficult question, and one in which there are many sources of error. We are dealing with one of the most complicated organs in the body and in using the laryngeal mirror are looking at things in perspective which are in almost constant motion. It is often important to say whether a vocal band stands motionless in the median line, or a few millimetres off from it. If we call every paralyzed vocal band we see a paralysis of the posterior crico-arytenoid muscle, we can multiply such cases very rapidly. The theory that there is a "proclivity" of the posterior crico-arytenoid fibres to become diseased is not only contrary to nature, but the dogmatic manner in which it has by some been advanced ought of itself to cause us to doubt its accuracy. He should feel sorry to have an association like our own subscribe to this notion on the very shallow evidence at present presented. The speaker desired to express his indebtedness to Dr. Bowditch, Professor of Physiology in the Harvard Medical School, and others connected with the department, whose assistance had been of value to him in the preparation of his paper.

DR. H. A. JOHNSON, of Chicago, next read a paper on

SOME OF THE MOTOR DERANGEMENTS OF THE LARYNX, WITH CAUSES,

in which he related the histories of over twenty cases, of unusual interest and value.

DR. WILLIAM C. GLASGOW, of St. Louis, next presented a paper on

CERTAIN VASO-MOTOR DISTURBANCES OF THE NASAL MEMBRANE.

He stated that for some time his attention had been attracted by a series of cases which were not explained by the well-known factors of inflammatory process. Resembling them somewhat, there were still differences which necessitated an additional and independent influence for their production. The laws of vaso-motor action, although still imperfectly developed, would seem to explain them, and the success attending the use of therapeutic agents verifies it. The observations of the writer had led him to arrive at somewhat different views than those developed by several members of this Society, especially by Drs. Mackenzie, of Baltimore, Roe and Daly, and by our colaborer Hack, of Freiburg. He had noticed a series of cases characterized by great swelling, especially of the cavernous tissue, and a profuse discharge of limpid fluid, and abnormal paleness of the mucous membrane. Formerly, when they occurred during the summer months, he had been content to consider them as modified types of so-called hay fever; occurring during the year, irrespective of seasons, he had become convinced that there was a different agency from that then recognized as the essential factor in hay fever. He believed that the chief part of the disturbance is neurotic, considering the so-called hay fever to be a functional disorder of the nervous system in which hypersensitiveness of the nasal mucus membrane occurs, producing there the well-known reflex symptoms and disturbances of the normal vaso-motor action. He still considers these cases as closely allied both in etiology and mechanism with the so-called cases of hay fever. He had selected three cases which showed the distinct and different types of nasal disturbance. The writer concluded that the condition is due to contraction of the arterioles due to an increased tone of the vessels caused by an augmented action of the constrictors. In short, the minute vessels supplying the arteries are in a state of spasm and dilatation. The general arterial tension is increased, the outward flow of the more solid portions of the blood is prevented, and the cavernous bodies of the mucous membrane become infiltrated with escaping white corpuscles and the liquor sanguinis. To these must be added the liquefaction and increase of the glandular secretions as the result of gland stimulation. The theory of spasm of the arterioles is supported by the favorable action of remedies which favor arterial dilatation, such as atropine.

The discussion was participated in by Drs. Roe, Robertson, Mackenzie, and Allen.

DR. JOHN N. MACKENZIE, of Baltimore, next read a paper on

REFLECTIONS ON THE ETIOLOGY OF THE SIMPLE INFLAMMATORY AFFECTIONS OF THE UPPER AIR-PASSAGES.

His conclusions were as follows: First. Inflammation of the upper respiratory tract, either in its entirety, or

Digitized by Google

localized in its individual parts, is a disease of the human race which has existed from the remotest period of historic times. Second. As the chief predisposing and exciting causes of the affection have been in operation for all ages, its origin is, therefore, coeval with the birth of man. Third. The evolution of nasal, pharyngeal, and laryngeal disease in a given locality is, in all probability, a part of its geological history, and goes on *pari passu* with its varying meteorological conditions. Hence, the geographical limits of the disease have varied with different epochs of the earth's formation.

The first portion of Dr. Mackenzie's paper was devoted to the elaboration of the above propositions. He next discussed in detail the chief predisposing and exciting causes proceeding from affections of the system as a whole, or disease of individual organs remote from the nasal passages, and the relations of syphilis, tuberculosis, gout, rheumatism, etc., to the affection in question. Having shown that nasal and laryngeal disease may proceed from a direct or indirect irritation, from a host of substances derived from the outer world, from an almost indefinite number of pathological conditions of the body as a whole, or from irritation or disease of organs distant from the seat of local inflammation, the reader proceeded to the discussion of the part which structural peculiarities play in the etiology of these affections, and to the consideration of the so-called catarrhal diathesis, which latter may be looked upon simply as a generic term for a multitude of varied physical peculiarities. Setting aside the inflammation which results from purely local irritation, it may be laid down as a law that the vast majority of catarrhal, pharyngeal, and laryngeal disease originates primarily in inflammation of the nasal cavities. He next quoted a number of causes efficient in the production of catarrh, and closed his paper with a proposition that in a large proportion of cases the existence of chronic inflammation in the nasal, pharyngeal, or laryngeal cavities is not due to any one particular cause, but is the resultant of a number of internal and external forces.

DR. COHEN then asked whether the climatic conditions referred to in the paper could not often be altered. The patient, however, could be protected by suitable hygienic and dietetic supervision. The functions of digestion and excretion must be attended to, the skin be kept in good order, and revulsive measures be adopted to withdraw morbid influences from the upper respiratory tract. Local measures without due consideration of constitutional conditions did not fulfil the requirements. Acute laryngitis occurred frequently in those not suffering with chronic catarrhal diseases and subsided without such a sequel. On the other hand, subacute inflammations had occurred most frequently in his experience in the subjects of chronic disease as exacerbations due to some special exposure. The spasmodic affections of infants alluded to in the paper as occurring in the subject of chronic naso-pharyngeal catarrh, were similar in origin to the night cough of infants, being due to trickling of mucus in the larynx. The indication, then, is to place the sleeping infant in a position which will not allow the entrance of secretion into the larynx and of course to treat the catarrhal disease.

DR. H. A. JOHNSON, of Chicago, remarked that naso-pharyngeal catarrh is common around our great lakes, and is frequently benefited by a change of climate to the western plains, up to an altitude of five or six thousand feet. In high mountains the disease is aggravated. General tonics are of great value.

DR. INGALS, of Chicago, also emphasized the necessity of attention to the constitutional condition, but said on the other hand we should not lose sight of the constitutional manifestations due to the nasal disease. In many cases great impairment of general health is dependent upon nasal obstruction, and remarkable improvement would immediately succeed removal of the nasal obstruction.

DR. GLASGOW, of St. Louis, believed that dust held a most important place in the production of catarrhal symptoms.

DR. ALLEN considered that local treatment in these was of great importance,

DR. MACKENZIE closed the discussion by stating that his position was, that the localization of catarrhal processes in the retronasal space, or the geographical limits of the disease, have little to do with the presence of dust in the atmosphere. While true that dust accidentally lodged in the nasal passages may give rise to inflammation, he believed that few cases originate in this way, for reasons which he had explained in his paper.

DR. D. BRYSON DELAVAN next read a paper on

ERYSIPELAS OF THE LARYNX AND PHARYNX.

The reader referred to the classic thesis upon this subject published by Cornil, in 1862, and stated that although well known to Hippocrates the subject had of late received so little attention, particularly in this country, that but one case had been reported; while Morrell Mackenzie stated in his *résumé* of it, that he had seen but four. Having given a short review of the subject, the writer proceeded to relate two original cases. In case first the disease originated in one tonsil. It spread over the pharynx and thence extended through the nasal cavities to the lips, face, and head. The patient suffered from marked cerebral symptoms of an acute form and two weeks after convalescence developed a condition of insanity which remained chronic. The next case occurred in an aged patient of rheumatic habit and broken-down constitution. She was attacked with what at first seemed acute laryngitis. The disease, however, spread in both directions involving both the lungs and the pharynx, producing in the former distinct and widespread broncho-pneumonia, and in the latter an intense congestion. Laryngoscopic examination showed the larynx to be tumefied and of a dark purplish color. There was no necessity for tracheotomy, however. The constitutional symptoms were comparatively slight. The patient recovered. The cerebral symptoms in "case first" were evidently due to an acute meningitis due to the influence of the systemic poisoning. This having become chronic, was the cause of the resultant insanity. The writer believed that erysipelas of the pharynx and larynx was not an uncommon affection, and urged that greater interest be taken in the recognition and recording of cases.

DR. DE BLOIS, of Boston, called attention to a case of this kind which he reported about a year ago.

DR. RICE, of New York, agreed with the writer in believing the disease of occasional occurrence among

Digitized by Google

the broken-down subjects met with in general hospital practice.

DR. ROE, of Rochester, had in a similar case applied a spray of alcohol with good success.

DR. COHEN suggested that from the well-known efficacy of the hydrochlorate of pilocarpin in facial erysipelas it might prove a valuable remedy in this special manifestation.

DR. DELAVAN, in closing the discussion, suggested that in the use of pilocarpin the dose commonly recommended was excessive. He had made an extended series of observations upon the effect of this drug, and believed that the dose of one-twentieth of a grain hypodermically should, as a rule, be the maximum when administered to the patient for the first time.

THURSDAY, JUNE 25TH.—SECOND DAY.

In the course of the business meeting

THE REPORT OF THE LIBRARIAN

excited much interest. During the last six months the library had been more than doubled, and the catalogue presented by the librarian showed a list of 25 bound volumes and 364 pamphlets. The support of the Association and of its friends was earnestly solicited.

The regular session of the morning was opened by the reading by title of a *Case of Submucous Laryngeal Hemorrhage Complicated by Cyst*, by DR. FRANK L. IVES, of New York.

DR. HARRISON ALLEN, of Philadelphia, then read a paper on

THE GALVANOCAUTERY IN LARYNGOLOGICAL PRACTICE,

with which he presented a new and original cautery snare. The snare was based upon the principle of the Jarvis instrument, excepting that a platinum wire was used and arrangements for attachment with the battery so that the snare might be used either cold or with the galvanocautery. Some interesting principles in the use of the instrument were explained.

A short and interesting paper upon *The Principles Involved in the Construction of Spray-tubes*, by DR. ANDREW H. SMITH, of New York, was then read by the Secretary.

A number of

NEW INSTRUMENTS

were next presented. The exhibition of improved electric lights and galvanocauteries was by far the most important ever presented to the Association, and the advances made in this department during the past year of extraordinary significance.

DR. COHEN presented an excellent accumulator, manufactured in Philadelphia, together with an electrical laryngoscope and other attachments.

DR. DEBLOIS presented a new powder-blower combined with a laryngeal mirror.

DR. ASCH presented two instruments—an osteotome for the removal of exostoses in the nasal passages, and a modification of the Jarvis snare, in which the wire was secured by a clamp instead of being wound around a pin.

DR. HOOPER showed the electric lamp and pocket-accumulator as perfected by Dr. Felix Semon and Mr. Arthur Vesey; manufactured by J. Weiss & Son, London.

DR. SEILER and DR. JARVIS also presented instruments.

The session of the afternoon was opened by the reading of an elaborate and highly interesting paper, by DR. E. FLETCHER INGALS, of Chicago, entitled

LEUCOPLAKIA BUCCALIS ET LINGUÆ, OR ICHTHYOSIS LINGUÆ: SUCCESSFUL TREATMENT BY THE GALVANO-CAUTERY.

During the past year it had been the author's good fortune to cure a case of the rare and intractable disease which formed the subject of this paper. The disease had been recognized but a short time, very little had been written upon it, and that little was involved in what at first seemed inextricable confusion. This because several different affections had been confounded and described under the same name. Thus, "smokers' patches," the condition found in old glass-blowers termed "professional patches," psoriasis linguæ, and various manifestations of syphilis, having been considered by different authors as true leucoplakia or as one of its phases. Prof. Ingals defined leucoplakia buccalis as a chronic affection of the buccal mucous membrane, characterized by thickening of the epithelium, and the formation of white, opaline, elevated patches, which usually become fissured and painful, and, after continuing for a long time are likely to terminate in epithelioma. A full history of the disease was given with copious references. The anatomical characters, causation, clinical history, and diagnosis were thoroughly considered. As to prognosis, the duration of the disease is uncertain. Two cases were referred to in which cancer supervened in less than six months. Among the indications that leucoplakia is passing into epithelioma were non-inflammatory enlargements of the lymphatic glands with exfoliation of the thicker portion of the patch, the formation of an ulcer, the supervention of sharp pain, salivation, and at length induration of the subjacent tissue; finally great swelling in the region of the jaw is likely to occur, and death takes place from exhaustion.

Treatment. In cases of leucoplakia all sources of irritation, particularly those resulting from the use of alcohol, should be at once removed, and if the digestive organs are deranged, as is frequently the case, they should receive proper attention. Aside from these measures, most authorities believe treatment of little or no avail. In the case reported in the paper, internal remedies were useless and local applications of tincture of iodine, nitrate of silver, and the acid nitrate of murcury greatly increased the patient's suffering, and would doubtless have aggravated the disease had they been persisted in. As soon, however, as the actual galvanocautery was applied, relief from all pain was obtained, and by a persistent and careful use of it the disease was eradicated. From a study of the literature of the subject and from his own experience, the author had arrived at the following conclusions: First, leucoplakia buccalis is an idiopathic disease distinct from psoriasis, "smoker's patches," and syphilis. It is largely confined to men past middle life, but occasionally occurs in women. Second, the disease is so commonly found in inveterate smokers that the abuse of tobacco may be fairly claimed as an exciting cause, though cases occur where tobacco has never been used. Third, the affec-

Digitized by Google

tion is chronic, and finally terminates, in a majority of cases, in epithelioma. Fourth, internal treatment and the local application of sedative, stimulant, or caustic drugs is in nearly all cases either useless or injurious, and the latter are sometimes disastrous by hastening the development of epithelioma. Fifth, the actual cautery or the galvanocautery will probably enable us to cure many cases, if they are treated sufficiently early, provided it is applied to only a small spot at each sitting and carefully, so as not to destroy the healthy tissue beneath the changed epithelium.

The author's case was then recited in detail and a complete bibliography of the subject appended.

In the unanimous opinion of the Association the paper of Dr. Ingals was a timely and important communication which could not fail to excite widespread interest.

DR. R. P. LINCOLN, of New York, contributed a paper in which he reported

A CASE OF MELANO-SARCOMA OF THE NOSE CURED BY GALVANOCAUTERIZATION.

A little over two years ago, patient first noticed an obstruction to free respiration in the right nostril. This was followed by continual mucopurulent blood-stained discharge. Her general health at this time was good, there was little or no pain. Six months later this nostril became completely occluded. The growth was then removed, and pronounced upon microscopic examination to be cancerous. Two months later the former symptoms reappeared, and continued to increase for eight months, when the first operation was again repeated. In the course of four months afterwards the tumor increased very rapidly, when the patient placed herself in the hands of a so-called "cancer doctor." The patient came under the observation of Dr. Lincoln in November, 1884. At this time the right side of the nose, extending to the inner canthus of the eye, showed a fulness amounting to about four times the size of the left side of the nose. The lower half of its ala was wanting, and there protruded from the right nostril for about half an inch a dark-colored, fleshy mass, which completely filled it. This was attached to the outer margin of the nostril as well as to its floor. A plum-colored discharge flowed constantly from the nostril, and the lightest touch by a probe upon the mass excited hemorrhage. Exploration showed the tumor to grow from the inferior and middle turbinated bones and from the floor of the nostril for a distance of two and a half inches. The septum was free.

The tumor protruded in the post-nasal cavity, occupying about half of it. Its removal was effected by means of the galvanocaustic écraseur, and a subsequent cauterization of points of attachment. Great pains were taken to make the cauterization complete, and thus secure the entire removal of diseased tissue. Hemorrhage was inconsiderable. A disinfectant solution was used for about a week after the operation. The patient was allowed to return home two weeks after the operation. On May 27, 1885, the patient having returned at intervals of one or two months since the operation, careful examination failed to reveal the slightest recurrence of the disease. A microscopical examination of the tumor made by Dr. Frank Ferguson of the Pathological Department of the New York Hospital, identified the tumor as a true melanotic sarcoma.

ANGIOMA OF THE NOSE.

In the next paper DR. J. O. ROE, of Rochester, New York, presented the history of an extremely interesting tumor of the nasal cavity, which the microscope proved to be an angioma. The subject in general was thoroughly discussed by the writer, and a full bibliography of the subject furnished.

DR. MACKENZIE remarked that certain cases of angiomatous nasal growths might be referred to the category of hypertrophic enlargement of the turbinated bodies.

DR. J. W. ROBERTSON, of Detroit, then read a paper on

DEFORMITIES OF THE NOSE AS A FACTOR IN NASAL CATARRH.

He inquired, first, What are the causes of the large number of deformed noses? Second, At what age do these deviations from the normal take place? Third, In what way do these deformities produce catarrhal diseases? And fourth, How can these abnormal conditions be prevented?

The author then related statistics from which it appeared that a large percentage of deformities of the nose were directly due to injuries received, syphilis, scrofula, tuberculosis, and allied diseases, which caused the necrosis, ulceration, and also congenital improper development. The deviations from the normal took place, according to statistics given by Dr. Robinson, in large proportion between the ages of ten and twenty years, either through the receipt of injury, or improper development due to malnutrition. These deformities, through the blocking up of secretions, a local malnutrition, or too free entrance of air, may give rise to catarrh. These abnormal conditions might be avoided by understanding that the time to prevent catarrh and its concomitant diseases is during the growing period of childhood. Deformities due to traumatism, such as fractures and dislocations, are more easily relieved in the young, and should be attended with as much care as corresponding injuries in a larger bone. In cases of syphilitic and scrofulous diseases, where the secretions are profuse and inclined to adhere to the mucous membrane, the constant irritation should be relieved by appropriate measures. Care as to hygienic surroundings and an attempt by proper treatment and feeding to develop, if possible, the bony structures of the nose in children, should be observed.

DR. MACKENZIE referred to the custom of the ancient Persians with reference to securing symmetry of the nasal chamber in the children of the royal blood.

DR. CLARENCE C. RICE, of New York, then read a paper on

INFLAMMATORY ADHESIONS OF THE SOFT PALATE TO THE WALL OF THE PHARYNX.

The author recognized the lack of success which heretofore has characterized the efforts of most operators for the relief of this condition. In considering the prognosis such cases should be divided into two classes, first where the sole lesion is the adhesion of the soft palate to the walls of the pharynx; and, second, where in addition to this, extensive cicatrization had narrowed the normal cavity of the naso-pharynx. The author paid a high tribute to the skill and success of the late

Digitized by Google

Dr. Elsberg in the treatment of these cases, and closed the paper with the relation of an original case in which he had operated with success.

FRIDAY, JUNE 26TH.—THIRD DAY.

DR. BEVERLY ROBINSON, of New York, presented a paper on

ALIMENTATION IN LARYNGEAL PHTHISIS,

which was read by the Secretary. The writer explained that three methods of treatment were in vogue for the alimentation of such patients: first, the method of superalimentation, advocated by De Bove and others; second, the method by means of a tube of small calibre passed a short distance into the œsophagus, and proposed by Delavan; and third, the method by rectal enema. All of these methods he explained somewhat in detail, and opposed against them certain objections, fortifying his conclusions by the quotation of several original cases. He strongly advocated the application to the ulcerated parts of cocaine, which greatly diminished the dysphagia and enabled the patient to swallow with comparative ease. Without the use of a local anæsthetic, however, such as cocaine, it was admitted that in some cases of laryngeal phthisis, when deglutition was otherwise painful, the patient might be sustained for months by means of injections of food into the stomach through an œsophageal tube. Moreover, that in those severe cases in which the passage of the œsophageal tube occasioned considerable pain, dyspnœa, or nervous exhaustion, and despite the previous local use of cocaine, recourse might be had, as heretofore, to the use of nutrient enemata judiciously managed.

DR. COHEN spoke favorably of the use of the small tube passed only part way into the œsophagus, which method he had used with good results.

DR. DELAVAN also defended the method on the ground that by the use of the tube ulcerated parts were protected from irritation; that the use of cociane was in many cases unsatisfactory; that the method, although not uniformly successful, would be found of value in a large number of these distressing cases, and objected to its condemnation by Dr. Robinson on the slender basis of two unsuccessful cases. As to the point raised by Dr. Robinson, that the method had been described by Dr. Frank Donaldson, in 1883, he desired to call the Association's attention to the fact that he had presented a full description of it in his candidate's thesis for the American Laryngological Association, submitted to the Council of the Association in the early part of 1880.

In the absence of DR. F. H. BOSWORTH, of New York, his paper, *An Additional Note on the Therapeutic Action of Cocaine*, was read by title.

A paper, upon *Personal Experience with some Recent Additions to the Materia Medica of Laryngology*, by DR. S. SOLIS-COHEN, of Philadelphia, was next presented. In this the author's experience with several new drugs was related, and many original and valuable suggestions communicated.

A paper, entitled *A Case of Membranous Nasal Catarrh*, in the absence of the author, DR. G. W. MAJOR, of Montreal, was read by title.

The literary exercises of the session were concluded by a discussion on

THE EFFICACY OF MILD MEASURES IN THE TREATMENT OF SO-CALLED NASO- AND NASO-PHARYNGEAL CATARRH,

which was opened by DR. COHEN, who argued that less radical measures than those now in popular use were frequently indicated, and suggested the importance of distinguishing between true hypertrophy and mere turgescence of the nasal mucous membrane. He advocated pressure as an efficient means for the reduction of turgescence, and suggested an ingenious method by which equable pressure could be employed. This was the introduction into the nostril of a laminaria tent, cut down until its cylindrical form had been reduced to a thin, flattened oval. This, in proportion to the size of the nasal cavity. The tent was to be introduced into the nostril, and, moistened by the nasal secretions, allowed to swell,—the patient meanwhile being directed to prevent the tent from swelling to such a degree that it could not easily be removed.

The discussion was participated in by Drs. DeBlois, Cooper, Asch, Rice, Mackenzie, and Shurly, and the views expressed by Dr. Cohen were very cordially received.

A vote of thanks was made by the Association to the Detroit Medical and Library Association, to the physicians of Detroit, and to the members of the Detroit press, from all of whom many courtesies had been received.

The ballot for

OFFICERS

resulted in the election of:

President.—Dr. Harrison Allen, of Philadelphia.

First Vice-President.—Dr. H. A. Johnson, of Chicago.

Second Vice-President.—Dr. George W. Major, of Montreal.

Secretary and Treasurer.—Dr. D. Bryson Delavan, of New York.

Librarian.—Dr. Thomas R. French, of Brooklyn.

Member of Council.—Dr. J. Solis-Cohen, of Philadelphia.

The *next annual meeting* will be held in the City of Philadelphia, on the last Thursday in May, 1886.

STATE MEDICAL SOCIETY OF WISCONSIN.

Thirty-ninth Annual Meeting, held at Milwaukee, June 2, 3, and 4, 1885.

(Specially reported for THE MEDICAL NEWS.)

THE PRESIDENT, E. W. BARTLETT, M.D., of Milwaukee, called the Society to order, and delivered an address which related chiefly to ethical questions, and was referred to the Committee on Ethics.

DR. MEACHER, of the Committee on Surgery, then presented a paper upon the

COMPARATIVE MERITS OF SYME'S AND PIROGOFF'S OPERATIONS,

in which he considered that Pirogoff's operation is better adapted to cases in which the patient cannot procure an artificial foot, while Syme's method of procedure gives a stump well adapted to the use of a substitute for the lost member: hence, the surgeon in adopting one or the other method must be guided to some extent by the circumstances of the patient. The

Digitized by Google

writer in closing referred to Chopart's operation with strong disapproval; he deemed its propriety very doubtful in any case.

In a second paper on

THE SURGICAL TREATMENT OF HEMORRHOIDS AND ANAL FISTULA,

he favored the treatment of hemorrhoids by ligature in preference to any other mode, and regarded the knife as being the only proper instrument to use in fistula, except only those cases as have the internal opening high up in the bowel while the external aperture is far removed from the anus; these cases he preferred to treat by the elastic ligature.

DR. S. MARKS, of the same Committee, presented the subject of

INGUINAL AND FEMORAL HERNIA,

and the duty of the surgeon in cases of strangulation. He thought that there is often a failure in exercising sufficient care in taxis; that no form of surgical practice demands greater patience on the surgeon's part, and that the writers on surgery generally fail to emphasize this matter sufficiently. Twenty years ago he would have considered a surgeon who failed to operate early in a case of strangulated inguinal hernia as guilty of malpractice, but later experience had caused him to change his opinion. If the symptoms are such as to indicate imminent danger, if the pulse is at 120 or over, if fecal vomiting is present, etc., he would still operate without delay, for in such a case there is no time to lose, and nothing whatever to gain by delay; but if the surgeon is called in due season, and before matters have reached so desperate a stage, he should place the patient fully under the influence of narcotics, keeping him narcotized for twenty-four hours or longer, and applying taxis from time to time. By so proceeding he had avoided the necessity of operating in a majority of cases within the last ten years. In femoral hernia he favored early operation, as otherwise the risk of forming artificial anus is very great; but in the inguinal form, so long as there is only ordinary bilious vomiting, while the pulse is strong and not too frequent and indications are otherwise favorable, he preferred to push narcotics, watching his patient carefully meanwhile, and to use the aid that position and taxis can give in preference to operating. While the danger of operating under antiseptic precautions is not great, and while by an operation you almost always make a permanent cure of inguinal hernia, still, Dr. Marks feels confident that by narcotism and delay in favorable cases, surgeons will lose fewer cases than have been lost in the past.

DR. SENN said that in every case of operation for strangulated hernia, he believed it to be the surgeon's duty to follow up that proceeding by excision of the sac and closure of the hernial ring, thus mechanically obstructing the outlet and preventing a relapse, or by replacing the sac within the abdomen, and uniting the ring sutures, and cited a case in point.

DR. ARMSTRONG, of the Committee on

OBSTETRICS AND GYNECOLOGY,

reported on recent progress in these departments of medical science. Among the points noted were the use of antiseptics and germicides, the employment of electricity to prevent hemorrhage, and the many forms of operation that have been brought to the notice of the profession in recent years.

DR. D. C. DAVIES presented a paper on the *Ignorant Use of Ergot in Obstetrics*, quoting in illustration a case that had occurred in his own practice, and Dr. H. J. Stalker offered a short account of an instance of *Arrested Development*, with photographs of the fœtus.

DR. LA COUNT exhibited a section of a femur, presenting a fine illustration of

CENTRAL OSTEOMYELITIS,

affecting the lower portion of the shaft, and showing the way in which adjacent joints became involved, thus adding to the gravity of the disease. Dr. Senn exhibited another, taken from a young subject, and showing the advantages of early surgical interference.

DR. WHITING, on behalf of the venerable Dr. Harmon Van Dusen, for more than thirty years an active member of the Society, and several times its president, presented the Society with a diploma issued by the Medical Society of the County of Onondaga, New York, in 1826. It was formally accepted, and the Society resolved that it should be placed for safe keeping in the rooms of the State Historical Society, at Madison, and that the sincere thanks of the Medical Society be conveyed to Dr. Van Dusen.

DR. J. M. DODSON read a paper on the

TREATMENT OF HYPERPYREXIA,

in which he considered the cold bath as the best means of combating fever, and thought that the difficulty attendant on its administration is the chief reason why it is not more frequently employed; he suggested that the portable rubber bathing tub offered a means by which the difficulty may be reduced to a minimum. The cold pack ranks next in usefulness, and the application of ice bags to the spine is also of great value. Where these means are not available, and the physician is compelled to rely on drugs, quinine is the most trustworthy resource, but it should be used in large doses; fifteen grains is the smallest dose that can be regarded as antipyretic, and much larger quantities may be safely given. Next to quinine, antipyrine is the best agent for reducing temperature, but it cannot be regarded as absolutely safe, its use having caused death in at least one instance, and having been followed by undesirable effects in others. Dr. Dobson thought that in the exanthemata of children too little attention is given to the temperature, and he feared that lives have been sacrificed which might have been saved had this point engaged the physician's consideration, and means been employed to meet it.

DR. F. W. EPLEY proposed for consideration and answer a question often propounded to the practising physician by the Pension Office, upon the reply to which hinged decisions materially affecting the welfare of many persons,

"WHAT WAS THE IMMEDIATE CAUSE OF HIS DEATH?"

The inquiry is a very simple one on the face of it, but, unfortunately, the answer returned by the physician to the Pension Bureau often failed to give the information sought. For instance, a soldier contracts rheumatism while in the service, and after repeated attacks is dis-

Digitized by Google

charged and pensioned. He gets on after a fashion, suffering from occasional attacks of the disease, for which he at first consults a physician, but failing to derive much benefit from treatment, ceases after a while to call on the doctor when attacked. In the end dropsy supervenes, the physician is again called in, and attends the patient until he dies. Now his pension ceases, his widow applies for a renewal on her own behalf, and the question is asked of the attendant physician, "What was the immediate cause of death?" How shall the doctor answer it? Dr. Epley believed that it is at times answered in such a way as to defeat the object which the Pension Bureau desired to attain.

DR. G. C. STOCKMAN, of the Committee on

NEW REMEDIES,

made a report. He considered that in the use of any remedy there should be clear indications therefor, and that the only foundation of such indications is scientific clinical observation. Cocaine, antipyrine, and paraldehyde will, he thought, prove valuable additions to the materia medica.

DR. G. H. FOX, of the same Committee, gave a verbal report of a case of periostitis from local injury, and of several cases of rheumatism treated with fluid extract of manacca.

DR. BUCKMASTER, of the State Insane Hospital, read a paper on

ILLUSTRIOUS INSANE,

among whom he ranked Cambyses, Nero, Caligula, Julius Cæsar, Mahomet, Joan of Arc, Luther, Dean Swift, Swedenborg, Chas. Lamb, and many other noted personages. Dr. Buckmaster also gave an account of a case of mysophobia, under his own observation, in which the patient was in constant dread of soiling her hands, in washing which she passed a large part of her time, while she utterly neglected cleanliness in other respects, and had worn underclothing unchanged for many months.

DR. WIGGINTON, of the Northern Insane Hospital, presented some

NOTES ON INSANITY,

and on the relation of the medical profession to the insane of the State. He considered that the insane hospital is too often regarded as being the last resort instead of an institution to which the first preference should be given, and that the delay resulting from this opinion is in many cases disastrous to the patients. A large proportion of the hopelessly incurable cases may be traced to the lack of proper treatment in their earlier stages, whereas by timely measures, such as are only practicable in an hospital, many of them might and probably would have been restored to health and usefulness. A prejudice against the hospital had been created in the public mind, which he thought was due in part to sensational and untruthful statements in the non-medical press, careless and exaggerated assertions made by patients and their friends, needless legislative investigations, and the like, and in part to the natural shrinking from the publicity required by the law preliminary to commitment, and to the extreme opinions entertained and expressed by some physicians with regard to hospitals and their work. Dr. Wigginton thought that a change in the law might be made with advantage, so that a certain class of patients would be enabled to avail themselves of the advantages of the hospital upon their own application and without the formality of examination and legal commitment, and that greater care on the part of physicians in making examinations when these are needful would also be a movement in the right direction. There were many cases of senile dementia which should never be sent away from their own homes, and even in cases of acute mania sometimes, the entrance to the hospital, especially when preceded by a long journey, was almost equivalent to a sentence of speedy death.

DR. GAPEN cited a case very similar to that described by Dr. Buckmaster. A young man of a New England family which had pretty nearly run out by reason of intermarriage and consequent hereditary influences, broke down from overwork and began to manifest peculiar anxiety as to personal cleanliness, and, in addition to this anxiety, he developed a fear lest through his neglect something involving terrible consequences would happen to some one else. Thus, if he crossed a railroad track he would examine it, lest there should be something amiss that might throw a passing train off, and return again and again to the survey lest some accident should happen for which he would be indirectly responsible; or he would worry over a stretch of sidewalk lest there might be an orange-peel which he might have forgotten to knock off, and in consequence of his failure to do so somebody might slip and break a bone. Dr. Gapen thought that the prospect of improvement in such cases was practically *nil*, as the insanity was often only the culminating point in a long series of family degenerations. He desired to make one other point, and to protest against the tendency to multiply names. If every idea or combination of ideas that the insane mind was capable of forming were to be taken as the base, a volume as large as Webster's unabridged dictionary would be too small to contain the nomenclature of insanity. We had already such terms as aidoimania, mysophobia, agrophobia, panomania, and a host of similar words, and almost every day brings out some new one. Every man who observed a fixed idea in any other man's brain seems to think himself bound to coin a new word which shall describe that idea, and it was time to call a halt.

DR. HAUSMAN said, in reference to Dr. Wigginton's suggestion, that physicians should exercise great care in making examinations for commitment to an insane hospital; that the line of demarcation between sanity and insanity is very obscure; and that consequently the difficulties in the way of an examining physician are frequently great. He is called upon by the county judge to examine a patient whom neither he nor his coadjutor has ever seen before, and is expected to decide authoritatively—off-hand, as it were—on the sanity or mental unsoundness of the case. Persons are brought to the county seat, it may be by their relatives or by the supervisors of a town, who say that these persons act as if they were insane—that it is unsafe to allow them to be at liberty—and adduce evidence in support of these assertions, and the examining physicians have only the very unsatisfactory opportunity afforded by one or two interviews in open court. What is the wonder if mistakes are sometimes made?

DR. GAPEN suggested that one means of avoiding

Digitized by Google

the difficulty of which Dr. Hausman had spoken, and it was one that every physician who was called upon to make such examination felt, would be to establish, at various points if practicable, but certainly at one readily accessible place, hospitals for temporary commitment, where patients conld be under observation for a sufficient time to enable a physician to make a correct decision with more certainty than is now sometimes possible. This whole matter is one of great importance to the physician, for he has not only the moral responsibility, but his reputation and sometimes his property is at stake. There have been cases where the examining physician has been mulcted in heavy damages, and even though this were not a consequence—though the prosecution may have failed, it was unjust to place a physician in a position which rendered him liable to such proceedings. A commitment to such an institution as Dr. Gapen had in mind, moreover, would not convey the idea of stigma which exists for many persons in connection with an insane asylum, and when after careful observation in such an institution an individual was finally removed to one of the State Hospitals, his friend could not feel that perhaps after all a great injustice had been done him, and would have no ground for reproaching themselves or anyone else.

DR. BERWIG discussed *Medical Humbugs, Regular and Irregular*, at considerable length, pleading for greater stringency in the conditions of admission to medical colleges at the beginning, and for such action on the part of the profession as should refuse recognition to unqualified practitioners, whether the possessors of diplomas or not.

DR. MCARTHUR, of La Crosse, reported a case of

SERIOUS INJURY TO THE LEFT ANKLE,

in which both malleoli were fractured and a cut opening directly into the joint was produced. After careful consideration it was decided to make an attempt to save the limb; the fragments were placed in apposition and retained by a plaster-of-Paris dressing. The wound was treated on antiseptic principles with excellent results. The accident occurred, July 14, 1884, and on Jan. 15, 1885, the patient made her first attempt to walk without crutches. At date of the report "motion was perfect and, except for the fact that the joint had not entirely recovered its strength, it was as useful as its fellow. All that remained (visible) to tell of the accident was a slight scar.

DR. G. F. WITTER reported a case of

OPERATION FOR HARELIP AND CLEFT PALATE

at four weeks of age. Deformity was very great, and it was exceedingly difficult for the child to take nourishment. The operation was a successful one, and the Doctor's plea was for early operations in similar cases.

DR. PARKHAM read a brief paper on the

DIAGNOSTIC VALUE OF KOCH'S CHOLERA BACILLUS,

claiming that the answer to the question, whether the bacilli were pathogenic of cholera, must, with our present knowledge, be in the affirmative. In any case of choleraic diarrhœa, the patient should be isolated as a matter of precaution, and this being done, the microscope would enable the physician to make his diagnosis with scientific exactness, and with hardly a possibility of mistake. A microscopic examination of the dejecta of the first cases, followed up by culture experiments for from thirty-six to forty-eight hours would render sanitary authorities complete masters of the situation. Both methods should be employed, as the microscope alone is sufficient in but few cases, while absolute certainty is attained by the aid of culture-experiments. The paper was illustrated by microscopic specimens, including a slide prepared by Koch himself.

DR. EPLEY of the Special Committee on the

RELATION OF THE MEDICAL PROFESSION TO COURTS OF JUSTICE

appointed at the preceding meeting of the Society made a report. The Committee had after consultation prepared a bill, which had been introduced into the Legislature, but had failed to receive favorable consideration. The Wisconsin Legislature at its last session, was made up very largely of men who failed entirely to appreciate the character and value of expert testimony, and deemed it no different from the testimony of an ordinary witness to the facts. "There is a doctor; he knows something about a given case; why shouldn't he be called upon to testify to what he knows just the same as any other man having knowledge concerning it, and why should he set up a claim for special compensation rather than any other witness?" That is the idea that the majority of legislators have upon the question, and they won't talk with you about the matter.

DR. G. H. FOX considered that there was but one way for the medical profession to assert itself with dignity in the matter of expert testimony, which was to refuse to testify unless properly remunerated. Let a subpœna be issued for any member of this Society, and let him refuse to obey; then a bench warrant would probably issue and the doctor would be brought into court. Then he could refuse to testify and would be committed for contempt; the whole matter could then be brought before the Supreme Court, and an authoritative decision had upon the question, which was something that had not been obtained in any State in the Union he believed. For his own part he would take the course indicated, provided the Society would support him in so doing.

DR. BYERS said that he had been a member of the Legislature before which the bill mentioned by Dr. Epley had come, and he believed that the prospect of getting such a bill through either the Assembly or the Senate was hopeless, and that the course suggested by Dr. Fox was much more promising of favorable results.

Dr. Byers thought, however, that a physician who proposed to carry out the plan should refuse to be sworn when on the witness stand, rather than refuse to testify after being sworn; it was possible that if he were to take the oath the law could compel him to testify.

DR. GAPEN had given the matter a good deal of attention, as it was a question that came up in the course of his lectures to the law students at the State University every year. It seemed to him that the law was explicit. There was nothing said in the summons for an expert witness which differed from an ordinary summons; the summons having been issued and duly served, he thought that the doctor was bound to obey it so far as his appearance in court was concerned, but he thought

Digitized by Google

that if he refused to testify, and were committed for contempt, and a test case made for the supreme court, that court would sustain him in his refusal. In any event the whole business would thus be brought prominently before the public. If Dr. Fox were prepared to undertake the battle, he believed that the Society should sustain him in so doing, and if a favorable decision could be obtained, it would be an advantage to every physician in the State and in the country at large. He moved that an assessment be levied on the members of the Society for the purpose of meeting the expenses of carrying a case to the supreme court.

DR. EPLEY, in seconding the motion, said that he thought not only the members of the State Medical Society but the profession throughout the State would willingly contribute to such a fund, and that looking at what the Legislature had done in other directions, he thought it high time that the physicians of the State should demand proper consideration.

DR. MCLEOD said that he had been recently summoned to testify as an expert in the United States Court, and had asked the judge if he were compelled to testify not knowing anything of the facts in the case, and what the result would be if he refused. The judge replied that no precedent had been established, but that if the doctor chose he could refuse to testify, and by making a test case have the question settled. Dr. McLeod was not at that time in a position to undertake the work with all the inconvenience and trouble attendant on it, but that if he were called upon hereafter, he thought that he would refuse to testify and carry the question to the supreme court.

DR. GAPEN changed the form of his motion so that it stood that a committee be appointed to assess the Society a reasonable sum to carry the whole matter on a test case before the supreme court. It does not seem worth while to carry it beyond the Supreme Court of Wisconsin; a decision there will be all that the members of this Society need, and the decision of the supreme court of one State is respectfully considered by the courts of all other States. The motion was carried.

The Society then proceeded to the

ELECTION OF OFFICERS,

which resulted as follows:

President.—Dr. G. M. Steele, of Oshkosh.

Vice-Presidents.—Drs. S. C. Johnson, of Hudson, and D. C. Davies, of Columbus.

Committee on Ethics.—Drs. Barnett, Russell, and Armstrong.

Censor, for three years.—Dr. Senn.

Permanent Secretary.—Dr. J. T. Reeve, of Appleton.

MISCELLANEOUS BUSINESS.

Fraternal greetings were exchanged with the Ontario Medical Society, which was in session at the same time; and communications from the State Medical Society of Nebraska, relative to inter-State representation; from the Medical Society of New Jersey, relative to medical education; and from the Association of Medical Superintendents of Institutions for the Insane, relative to the immigration of the defective classes, were received, and referred to appropriate Committees for action and report.

A communication from the American Medical Association, relative to the establishment of Boards of Medical Examiners in all States, was received, and the general plan proposed by the Association was cordially approved by the Society.

A banquet at the Plantation House was the marked social feature of the session, and was highly enjoyed by those who participated in it.

Before closing the session, which was, in several respects, one of the most important in the history of the Society, the Committee on

ETHICS,

to whom was referred the President's Address, reported the following resolution, which was unanimously adopted:

Resolved, That the State Medical Society of Wisconsin hereby reaffirms its steadfast adhesion to the Code of Ethics of the American Medical Association.

The next session of the Society will be held in the City of Madison, on the first Tuesday in June, 1886.

MONTREAL MEDICO-CHIRURGICAL SOCIETY.

Stated Meeting, June 12, 1885.

VICE-PRESIDENT, EDW. H. TRENHOLME, M.D., IN THE CHAIR.

A CASE OF TETANY.

DR. STEWART exhibited a man aged 39, who for the past five years had been the subject of well-marked tetany. He had served as a soldier during the late American civil war, and had had three distinct malarial attacks during this period. He also suffered from chronic dysentery for about eighteen months. For the past seven years he has seldom or never been free from diarrhœa. Never had either rheumatism or syphilis. Family history good. The following is a description of the case: Every two weeks he is seized with a spasmodic contraction of the muscles of the fingers; the thumbs become adducted and opposed, the fingers flexed and abducted. This contraction comes on at times suddenly, but usually slowly, and remains from eleven to twelve days, when it passes away, leaving the parts in a normal condition. The spastic condition slowly increases day by day until it reaches its acme on the twelfth day. The return to the normal seldom occupies longer than twenty-four hours. At times the flexors of the forearms are strongly contracted, and also the adductors of the upper arms, causing the arms to be crossed in front of the chest. The muscles of the lower extremities are only occasionally involved, and then to a slight extent compared with the hands and arms. The facial muscles feel stiff and painful during the period of contracture, and they are the seat of constant fibrillary twitchings, which are much increased on tapping. The patient says that he experiences a sensation in his face as if the skin was too tightly drawn. During the period of spastic contraction he has diplopia. The electrical reactions of the muscles and nerves are enormously increased when he is suffering from the spasms, but after these have have passed off, the reactions are normal. Last week when there was marked tetany, 0.25 of a milliampère was sufficient to bring out K. s. z.—on irritation of the radial; but at present, when his muscles are in their normal state, it takes fully 4 (normal) milliampères to produce this contraction. This

Digitized by Google

strength of current produces tetanus in shutting the kathode (*κcτε*), and opening the anode (*αοτε*). There is no change in the normal formula, the K. s. z. < a. o. z. The great increase in the galvanic irritability is not confined to the radial, but is present also in the ulnar, facial, and other nerves. The disproportion between the faradic irritability in the normal and spastic states is not marked. There is marked increase in the mechanical action of the nerves and muscles. Steady pressure on either has the effect of increasing the spasms. The patellar reflexes, which are greatly exaggerated during the tetany, are scarcely to be brought out when it has completely passed away. The same applies to the biceps and triceps reflexes. The tongue, is raw, appetite fair. He is seldom free from diarrhœa, the average number of stools during twenty-four hours being about six. They are copious, frothy, semifluid, and have a pea-soup appearance. The urine is acid, normal in quantity, sp. gr. 1030, contains a large amount of urea and indican, but it is free from both albumen and sugar. The heart and lungs are normal. There is no increase in the white blood cells, no hepatic or splenic enlargement. The case differs from those hitherto published in the marked chronicity and the persistence of the spasms for days in place of hours.

Dr. Stewart, after referring to the usual causes of this disease, such as lactation, diarrhœa, and the so-called rheumatic influence, gave a description of that peculiar variety which follows extirpation of enlarged thyroids. While the former are nearly always recovered from, the latter are fatal. A description was given of a section of cervical cord of a young girl who died from tetany twelve months after removal of enlarged thyroid. No change of any apparent import could be discovered in this section. Dr. Stewart remarked that nothing definite as to the true nature of this remarkable disease is known.

In the discussion which followed the reading of the paper, DR. GEORGE ROSS said he would like to ask Dr. Stewart the mode of death in the fatal cases he had seen. The disease is such a rare one in this country that he had seen but few cases.

DR. HENRY HOWARD, after alluding to the various disorders of the nervous system allied to tetany, said that in his opinion a more complete anatomical and physiological knowledge of the nervous system is necessary before the exact cause of these cases can be positively known; but he thought that some irritation or inflammation of the vaso-motor nervous system may account for this disease. He had strong hopes that in the near future, with the many workers and varied means of research, the cause of diseases such as cancer, tetany, etc., will be found, and when recognized early that they may be successfully treated.

DR. GODFREY had seen several cases of tetany, or a disease like it, during the last fifteen years.

DR. SHEPHERD asked why it is that tetany is so much more common on the Continent of Europe than in America or England, epidemics of the disease being unknown in either place, and whether tetany is more common in the dark races, as is tetanus.

DR. R. J. B. HOWARD said it is remarkable that two such different diseases as myœdema and tetany should occur so commonly after extirpation of the thyroid gland. They occur in animals as well as man. He suggested that where possible the isthmus only of the thyroid should be removed, as in the 150 experiments of removal of the isthmus, performed by Victor Horsley on animals, none suffered from tetany.

DR. WILKINS said that although he had never had a case of tetany, he was much interested in the disease, and thought it probably due to irritation of the peripheral nerves, as these cases always follow diarrhœa, removal of the thyroid, or some other lesion.

DR. STEWART, in reply, said that in the fatal cases he had seen there was spastic contraction of the respiratory muscle and bronchitis. He could not tell the reason of the frequency of the disease in Europe; of course, removal of the thyroid is a very common operation there, and this would account for some of the cases, but not the epidemic form. He had seen 60 to 70 cases in the General Hospital at Vienna at one time. So frequently did this disease follow extirpation of the thyroid, that Billroth had given up operating for bronchocele, except in cases where the tumors endangered life. He was not aware of the disease being known in the West Indies, or that it is more frequent in the negro race. As to the theories advanced to explain its nature, he thought that advanced by Weiss, of Vienna, as the most probable. Weiss looks upon the origin of the trouble as due to irritation of the sympathetic, waves of dilatation and contraction being alternately set up.

CORRESPONDENCE.

THE INTERNATIONAL SANITARY CONFERENCE.

The excursion to Naples proved to be a very enjoyable affair, and afforded the delegates to the Sanitary Conference an opportunity not only to see Pompeii and other points of interest in the vicinity of Naples, but also to become better acquainted with each other, and to discuss, in a quiet way, the various subjects in which they were specially interested. From the time of leaving Rome—Monday morning—until their return on Thursday evening, the delegates were the guests of the Italian Government, and nothing which could conduce to their comfort or pleasure was overlooked.

For your correspondent, the most memorable event of the journey was a long conversation with Dr. Koch upon bacteria in general and the comma-bacillus in particular. It is evident that Dr. Koch has full faith in his own most recent discovery, and believes that the etiological relation of the comma-bacillus to cholera will soon be generally, admitted notwithstanding the adverse report of Dr. Klein. It was my intention upon leaving home to go to Berlin immediately after the adjournment of the Conference for the purpose of visiting Dr. Koch's laboratory, but having learned from him that it is just now in a state of confusion owing to a change of location, I have abandoned this idea at present.

From a sanitary point of view, the only thing of interest which we saw in Naples was the new water-works, which the mayor of the city exhibited with justifiable pride. A pure supply is obtained from distant mountain streams, and the only novel feature consists in the storage reservoirs, which are all under ground. We were conducted to the summit of a hill within

Digitized by Google

the city limits, and then descended, by means of a winding staircase, into a well fifteen or twenty feet in diameter. This central shaft is connected at various levels with arched passages which lead to the reservoirs, which are of enormous capacity and quite equal to the wants of the city. We were conducted through one which is not yet in use. All of the excavations have been made in the soft volcanic tufa which underlies the city of Naples. This has the advantage of being easily worked and of affording substantial walls and ceiling without any masonry or other support. The reservoirs are made water-tight by the application of Portland cement directly upon the natural walls of tufa.

It will be interesting to note the difference in the mortality rate of this city, which has long been noted for its insanitary condition, as a result of this great sanitary improvement, the completion of which was recently celebrated by a visit of the King, by civic ceremonies, and by general festivities and rejoicings. If this is followed, as is now contemplated, by an elaborate and well-considered system of sewerage, it may prove that the recent visitation of cholera was a blessing in disguise, for under the stimulus of this scourge sanitary improvements are being pushed with vigor, and we may yet see the mortality reports of this old Italian city put to the blush many of our prosperous American cities which have far less excuse for their sanitary sins.

The day after the return to Rome the Conference reconvened, and the detailed report of the proceedings of the technical subcommission was placed in the hands of each delegate. A printed abstract of the conclusions reached had also been prepared, but was so full of errors that it could not be accepted. Upon motion, the learned president, Dr. Moleschott, was requested to prepare an abstract for the use of the delegates.

After the transaction of certain routine business, the diplomatic delegate from Germany, Baron Kendall, took the floor and complimented the technical delegates upon their assiduity and upon the results of their labors. He then proceeded to say that at an informal conference of the diplomatic delegates present, it had been agreed that it would be necessary to confer with their respective governments before any definite action could be taken in the way of establishing an international convention upon the basis of the report of the technical subcommission. For this reason it was thought desirable that the Conference should now adjourn to meet again in the autumn. This proposition was adopted unanimously; and the following day, at the suggestion of the Italian Government, the Conference adjourned, to meet again on the 16th of November.

The same evening I started upon my return journey, going by way of the St. Gothard tunnel, through Switzerland to Mayence on the Rhine, down this river to Cologne, and then by rail to Brussels. One object in visiting this city was to call upon Dr. Van Ermengem, to whom I had a card of introduction from Dr. Koch, but I learned that he had been absent for three weeks in Spain, where he is no doubt pursuing his studies with reference to the "comma-bacillus." We shall no doubt hear from him in due time through the medical journals, and also from Dr. Roux, of Pasteur's laboratory, who has been sent by the French Government to pursue similar studies, and especially to investigate the claims of Dr. Ferrán.

By the way, I have not met with any expert in bacteriological researches who is inclined to attach great importance to these inoculation experiments. The newspaper reports have not been of a nature to inspire confidence in their scientific value on the part of such men as Pasteur, Koch, and Watson Cheyne. But, in the absence of full details as to methods and results, it is of course impossible to attempt to pass judgment in the case, and we must wait for the report of the experts now on the spot—Van Ermengem and Roux—who will doubtless give us an impartial judgment founded upon the facts.

From Brussels, I went directly to London. The few days at my disposal before sailing gave me an opportunity to make the acquaintance of the leading English investigators in bacteriology—Watson Cheyne and Klein. The first-named gentleman is just now engaged in an interesting research with reference to an infectious disease of the honey-bee, known to bee-keepers as "foul-brood." This he finds to be due to a bacillus which he has been able to cultivate, He was kind enough to present me with a pure culture of this bacillus, and also of several other microörganisms not in my collection.

As is well known, Watson Cheyne is the principal defender of Koch's "comma-bacillus" in England. He showed me a pure culture of this in gelatine, side by side with a culture of Finkler's curved bacillus, and pointed out the difference in the mode of growth of these two organisms, which are doubtless distinct, notwithstanding their close morphological resemblance. Dr. Klein also showed me cultures of the comma-bacillus in gelatine, from stock which he obtained while in India, and also slides, mounted on the spot, from the mucous flakes in the dejections of cholera patients, in which, as he pointed out, the comma-bacilli were associated with a variety of other forms, and were not especially numerous. Klein lays great stress upon the fact that curved bacilli, which he says cannot be distinguished from Koch's "comma-bacillus," are found in considerable abundance in the alvine discharges of healthy guinea-pigs—the animal upon which successful inoculations have been reported by Koch and others. Evidently this fact has no more significance than the fact that curved bacilli are found in the healthy human mouth and elsewhere, unless it is also shown that these curved bacilli from the intestine of the guinea-pig are identical with the "comma-bacillus" as regards their mode of growth in gelatine, and in their physiological characters as determined by inoculation experiments.

We will no doubt have further reports from Klein shortly, upon the cholera question, as he is now engaged in repeating Koch's inoculation experiments. Thus far he has not obtained any results which induce him to change the opinion which he has heretofore expressed as a result of his researches in India.

Dr. Klein has a well-equipped laboratory and is evidently not only an enthusiastic investigator, but a skilful manipulator. His methods of making inoculations —which he kindly showed me—and of conducting culture experiments were beyond reproach. But in my

Digitized by Google

conversation with him I received the impression that he has not a strictly judicial mind in estimating the value of experimental evidence which comes from sources outside of his own laboratory.

BOSTON.

(From our Special Correspondent.)

THE INTERNATIONAL MEDICAL CONGRESS AND THE MEDICAL PROFESSION OF BOSTON.—At a meeting of a number of members of the medical profession of Boston which was held on Thursday, July 2d, the following preamble and resolution were adopted:

Whereas, We had been led to believe that the authority to organize and control the Ninth International Medical Congress had been permanently delegated by the American Medical Association to its original committee, thus providing against any radical changes in its published programme; and

Whereas, The American Medical Association has revised the action and annulled appointments of that committee in a way which we regard as detrimental to the interests of the medical profession of America and fatal to the success of the Congress; therefore, be it

Resolved, That we, the undersigned, members of the medical profession in Boston and vicinity, concerned in the organization of the Ninth International Medical Congress, decline to hold any office in said Congress as now organized:

Robert Amory,	George M. Garland,
Clarence J. Blake,	J. Orne Green,
Henry P. Bowditch,	Frederick I. Knight,
James R. Chadwick,	Francis Minot,
Hasket Derby,	Oliver F. Wadsworth,
Thomas Dwight,	J. Collins Warren,
Robert T. Edes,	Samuel G. Webber,
Reginald H. Fitz,	E. Wigglesworth,
Charles F. Folsom,	Henry W. Williams,

H. P. Wolcott.

WASHINGTON.

(From our Special Correspondent.)

THE COLUMBIA LYING-IN HOSPITAL.—An investigation has been made recently in the Columbia Lying-in Hospital, at Washington, D.C., of its surgeon in charge, Dr. P. J. Murphy, on charges of irregular habits, bad manners, and general mismanagement, instigated possibly by some patient or subordinate, who has become liable to unfavorable criticism. We learn that the investigation has resulted in the complete exoneration of Dr. Murphy, by a vote of 11 to 2 of the Board of Management, from all the charges brought against him, with an additional vote of entire confidence in his ability, and satisfaction at his management of the institution. The Board of Lady Visitors have also passed a unanimous vote in similar language, and of such a character as cannot be but very gratifying to Dr. Murphy.

We regret, also, to see such charges made common gossip in newspapers, for, unless well established at the outset, they should be kept as private matter.

BALTIMORE.

(From our Special Correspondent.)

THE INTERNATIONAL MEDICAL CONGRESS AND THE MEDICAL PROFESSION OF BALTIMORE.—In consequence of the dissatisfaction caused by the recent action of the new Committee on the Organization of the Ninth International Medical Congress, the subjoined paper has been signed by those whose names are appended.

Whereas, The new Committee on the Organization of the Ninth International Medical Congress, at its recent meeting, held in Chicago, made such changes in the arrangements for the Congress as, in our opinion, will mar its success, and will prove injurious to the interests of the medical profession, it is therefore,

Resolved, That we, the undersigned, disapprove of the action of the Committee, and decline to accept the positions to which we have been appointed under it:

I. E. Atkinson,	Richard McSherry,
S. C. Chew,	F. T. Miles,
Julian J. Chisolm,	Alan P. Smith,
Christopher Johnston,	Samuel Theobald,
William Lee,	L. McLane Tiffany,
John N. Mackenzie,	H. P. C. Wilson.

CHICAGO.

(From our Special Correspondent.)

CHICAGO MEDICAL COLLEGE.—At a recent meeting of the Board of Trustees of the Northwestern University certain changes were made in the Faculty of the Medical Department, Chicago Medical College. Professor E. O. F. Roler, M.D., was elected Emeritus Professor of Obstetrics. Dr. W. W. Jaggard was elected Professor of Obstetrics.

Dr. Christian Fenger tendered his resignation as Professor of General Pathology and Pathological Anatomy. The resignation was accepted, and Dr. N. S. Davis, Jr., lecturer on the same subject, was selected to fill the vacancy during the coming year. Dr. Davis has been studying gross pathology under Kundrat, in Vienna, and pathological histology under Arnold, in Heidelberg, for a considerable period of time.

COLLEGE OF PHYSICIANS AND SURGEONS.—Dr. N. Senn, of Milwaukee, Wis., has accepted the Chair of Principle and Practice of Surgery, and Professor Christian Fenger, M.D., that of Clinical Surgery in the College of Physicians and Surgeons of Chicago. The strength of the Faculty is materially increased by its recent accessions.

SANITARY MEASURES IN CHICAGO.—Dr. Oscar C. De Wolf, Health Commissioner of Chicago, has been granted $100,000 for the purpose of improving the sanitary condition of the city. He has appointed thirty-four inspectors, and hopes to inspect fifty thousand houses before the middle of August.

Complaints, with reference to the smoke nuisance are pouring in upon the Health Commissioner, and Smoke Inspector Merki has instituted suit in over forty cases.

HYPNOTISM.—At a meeting of the Chicago Medical Society, held early in the spring, Dr. Charles Gilbert Davis read a paper, entitled, "Hypnotism," and illus-

Digitized by Google

trated the power of mesmerism, by putting a subject, whom he had brought with him, soundly to sleep. A second subject was put to sleep, and the two were placed on the floor. At the command of the doctor, one of the young men appeared to waken with a start. He was then placed in a chair, put to sleep again, and his arms and legs were extended. The first subject was awakened, again mesmerized, commanded to open his eyes and see the ghost of General Washington. The subject opened his eyes, gazed intently before him for a moment, when an expression of fear came over his face, and he started back, and fell to the floor in a convulsive movement, his eyes bulging out, the muscles of the neck perfectly tense.

The second subject was mesmerized, told he was Vanderbilt, and that his pockets were full of gold. The subject immediately replied: "That's right; my name's Vanderbilt. I've got lots of stuff. Won't you come out and take a drink?" Various performances of a similar character occurred, and the topic was opened for general discussion.

The author of the paper was highly complimented for the clearness and distinctness with which the topic was discussed in his paper. The order of ideas and facts was systematic, and the conclusions logical; the words were fitly chosen, the sentences were constructed with a very nice sense of style. Very general scepticism was expressed, however, as to the nature of the demonstrations of the influence of mesmerism upon the two subjects.

DR. WILLIAM E. CLARKE referred to an unhappy demonstration, before the International Medical Congress in London, of the effects of *syngignosticism*, by an American medical gentleman from the North Atlantic seaboard. He expressed a very positive conviction that Dr. Davis had practised a grave imposition upon the members of the Society. An animated debate followed, and the Society adjourned at a late hour, after the appointment of a committee of investigation.

A reporter for *The Chicago Times*, who had gained access to the meeting, recognized one of the subjects as a professional "horse," belonging to a West Side dime museum. A "horse" is an individual whose business it is to pose as a medium. The "horse," recognizing the reporter, besought him, in a whisper, not to disclose the secret. The secular press has teemed with leaders upon the evening's developments ever since. Dr. Davis has published the affidavits of his subjects in several daily papers, to the effect that they were not "horses," and were really under mesmeric influence.

At the stated meeting of the Chicago Medical Society, June 1, 1885, the committee of investigation, of which Dr. Charles Warrington Earle, Dr. Edmund J. Dorring, and Dr. Frank L. Wadsworth were members, made a report, which, upon motion, was accepted, and ordered to be given to the secular press.

The report of the committee alluded to three topics:

I. Upon investigation it was found that the paper entitled "Hypnotism," by Dr. Charles Gilbert Davis, was plagiarized from the *Encyclopædia Britannica*.

II. The subjects illustrating the paper were "horses," that is, imposters. The members of the committee were willing to admit the possibility that Dr. Davis was himself deceived by these men.

III. The strong statements made by Dr. William E. Clarke were true, and merited applause.

The paper and the discussion were expunged from the Society's records.

MONTREAL.

(*From our Special Correspondent.*)

CANADA MEDICAL ASSOCIATION.—The meeting of this Association for 1885 was to have been held in Winnipeg, Manitoba; but, owing to the troubled state of the Northwest, and the consequent absence of many of the medical men, it has been found impossible to make the necessary arrangements to hold the meeting at that place. The Association, however, will meet in Chatham, Ontario, on the 2d and 3d of September,—a cordial invitation having been received from the members in that neighborhood. It is expected that the meeting will be a large one, and already many papers have been promised. Prof. William Osler is the President-elect.

PERSONAL NOTES.—Dr. D. Bergin, M.P., has been elected President of the College of Physicians and Surgeons of Ontario.

Dr. Laberge has received the appointment of Medical Health Officer to the City of Montreal.

Dr. T. Johnson-Alloway, at a recent meeting of the Governors of the Montreal Dispensary, was elected Gynecologist to that institution; and Drs. R. J. B. Howard and J. A. MacDonald, Attending Physicians.

THE CHICAGO COMMITTEE'S ORGANIZATION OF THE INTERNATIONAL MEDICAL CONGRESS.—In response to numerous requests, we publish herewith the changes which were made in the Councils and Secretaryships of the various Sections, which, in connection with the report published last week, completes the list of changes thus far made.

Section of Medical Education, Legislation, and Registration.—Drs. N. S. Davis, of Chicago, and J. H. Rauch, of Springfield, Ill., were omitted from the Council, and the following added: Drs. C. L. Allen, of Rutland, Wis.; J. A. Dibrell, Jr., of Little Rock, Ark.; H. O. Hitchcock, of Kalamazoo, Mich.; J. W. Bailey, of Gainesville, Ga.; and H. King Wylie, of Sanford, Fla. Drs. Mixter and Whitney, of Boston, were stricken out as secretaries, and Dr. E. F. Dunbar, of Boston, was substituted.

Section of Anatomy.—Dr. Burt G. Wilder was stricken from the Council, and Drs. A. Hewson, of Philadelphia; George Halley, of Kansas City; and M. S. Craft, of Jackson, Miss., added.

Section of Physiology.—Drs. H. P. Bowditch, of Boston; H. F. Campbell, of Georgia; and S. Weir Mitchell, of Philadelphia, were omitted from the Council, and there were added Drs. W. F. Hyer, of Holly Springs, Miss.; J. H. Wythe, of San Francisco; Thos. S. Latimer, of Baltimore; A. F. Whelan, of Hillsdale, Mich.; S. Putnam, of Montpelier, Vt.; C. H. A. Kleinschmidt, of Washington; and A. D. Brubaker, of Philadelphia.

Section of Pathology.—From the Council, Drs. Thos. S. Satterthwaite, of New York, and James Tyson, of Philadelphia, were omitted, and the following added: Drs. C. H. Hunter, of Minneapolis; E. O. Shakespeare, of Philadelphia; H. D. Schmidt, of New Orleans; and

Digitized by Google

Morris Longstreth, of Philadelphia. Dr. T. M. Prudden, of New York, was stricken out as secretary, and Drs. H. M. Biggs, of New York, and I. M. Hines, of Cleveland, were substituted.

Section of Medicine.—Drs. W. H. Draper and Andrew H. Smith, of New York, and William Pepper, of Philadelphia, were dropped from the Council, and the following substituted: Drs. A. B. Arnold, of Baltimore; Jeff. Williamson, of Ottumwa, Iowa; T. B. Lester, of Kansas City; E. Grissom, of Raleigh; W. H. Phillips, of Canton, Ohio; J. P. Logan, of Atlanta; E. D. Ferguson, of Troy, N. Y.; J. Burnett, of Cleveland; W. W. Cleaver, of Lebanon, Ky.; S. S. Clark, of St. Albans, Vt.; and J. Draper, of Brattleboro, Vt. Drs. R. Harvey Reed, of Mansfield, Ohio, and Walter Hay, of Chicago, were added as secretaries.

Section of Surgery.—Drs. W. W. Dawson, of Cincinnati; Levi C. Lane, of San Francisco; Samuel B. Ward, of Albany; and Robert F. Weir, of New York, were omitted from the Council, and the following added: Drs. O. Coskery, of Baltimore; Jas. McCann, of Pittsburg; H. H. Mudd, of St. Louis; W. F. Westmoreland, of Atlanta; J. P. Wall, of Tampa, Fla.; Leroy M. Bingham, of Burlington, Vt.; F. A. Dunsmoor, of Minneapolis; J. T. Carpenter, of Pottsville, Pa.; W. S. Janney, of Philadelphia; J. E. Garrettson, of Philadelphia; I. N. Quimby, of Jersey City; H. H. Smith, of Philadelphia; J. R. Weist, of Richmond, Ind.; S. D. Mercer, of Omaha; T. A. McGraw, of Detroit; W. F. Andross, of Mitchell, Dakota; W. H. Austin, U. S. M. H. S.; C. A. Wheaton, of St. Paul; Thomas R. Russell, of Oshkosh, Wis.; and J. H. Ransom, of Burlington, Iowa. Dr. Dudley P. Allen, of Cleveland, was added as Secretary.

Section of Obstetrics and Gynecology.—Drs. M. D. Mann, of Buffalo; George H. Lyman, of Boston; Emil Noeggerath, of New York; and T. Gaillard Thomas were dropped from the Council, and the following were added: Drs. Donald McCrea, of Council Bluffs, Iowa; H. O. Marcy, of Boston; D. W. C. Wey, of Holly, Mich.; E. S. Dunster, of Ann Arbor, Mich.; Luke Robinson, of San Francisco; B. E. Hadra, of San Antonio, Mich.; R. S. Sutton, of Pittsburg; R. Glisan, of Portland, Oregon; William Varian, of Titusville, Pa.; C. V. Mottram, of Lawrence, Kansas; E. P. Sale, of Aberdeen, Miss.; T. B. Harvey, of Indianapolis; E. Warner, of Worcester, Mass.; and Lorenzo Fay, of Lowell, Mass.

Section of Ophthalmology.—Drs. Cornelius R. Agnew and Herman Knapp, of New York, and Samuel J. Jones, of Chicago, were dropped from the Council, and the following were added: Drs. Peter D. Keyser, of Philadelphia; David Hunt, of Boston; J. J. Chisolm, of Baltimore; John Green, of St. Louis; B. Joy Jeffries, of Boston; B. E. Freyer, of Kansas City; ——— Minny, of Topeka, Kan.; B. Baldwin, of Montgomery, Ala.; E. Smith, of Detroit; J. L. Thompson, of Indianapolis; A. G. Sinclair, of Memphis; and W. H. Sanders, of Mobile. Dr. Swan M. Burnett, of Washington, was made Secretary.

Section of Otology.—Drs. A. H. Buck, of New York; John Green, of St. Louis; S. O. Richey, of Washington; D. B. St. John Roosa and Samuel Sexton, of New York, were dropped from the Council, and the following added: Drs. C. S. Turnbull, of Philadelphia; C. J. Lundy, of Detroit; C. H. Burnett, of Philadelphia; E. H. Hazen, of Davenport, Iowa; S. J. Jones, of Chicago; J. C. Lippincott, of Pittsburg; and J. H. White, of Richmond. Dr. S. O. Richey, of Washington, was made Secretary.

Section of Dermatology and Syphilis.—Drs. L. Duncan Bulkley, E. L. Keyes, F. N. Otis, and R. W. Taylor, of New York, were stricken from the Council and the following were added: Drs. A. R. Robinson, of New York; H. R. Carter, U. S. M. H. S.; J. A. Octerlony, of Louisville; J. H. McAchran, of Laramie City, Wyoming Ter.; H. O. Walker, of Detroit; W. F. Glenn, of Nashville, and LeGrand B. Dinslow, of St. Paul. Dr. Arthur Van Harlingen, of Philadelphia, was dropped as Secretary, and Dr. F. E. Daniel, of Fort Worth, and W. T. Corlett, of Cleveland, were substituted.

Section of Laryngology.—Drs. F. H. Bosworth, of New York; E. Fletcher Ingals, of Chicago; and J. N. Mackenzie, were omitted from the Council, and Drs. R. P. Lincoln, of New York; C. E. Sajous, of Philadelphia; and H. Goldthwaite, of New York, were added, and Dr. E. F. Ingals, of Chicago, was made an additional Secretary.

Section of Public and International Hygiene.—Drs. A. L. Carroll, of Albany; C. A. Lindsley, of New Haven, J. N. McCormick, of Bowling Green, Ky.; and S. O. Vander Poel, of New York, were dropped from the Council, and the following added: Drs. J. B. Thornton, of Memphis; H. S. Orme, of Los Angeles, California; R. M. Swearingen, of Austin, Texas; H. Leffmann, of Philadelphia; C. M. Hewitt, of Red Wing, Minn.; E. L. B. Godfrey, of Camden, N. J.; W. L. Schenck, of Osage City, Kansas; Benjamin Lee, of Philadelphia; Dudley P. Hart, of Ark.; Joseph Holt, of New Orleans; W. S. Robertson, of Muscatine, Iowa; A. L. Gihon, U. S. N.; E. S. Elder, of Indianapolis; O. C. DeWolf, of Chicago; H. F. Lyster, of Detroit.

Section of Collective Investigation, Nomenclature, Vital Statistics, and Climatology.—Dr. A. Jacobi, of New York, was stricken from the Council, and there were added: Drs. A. C. Hamlin, of Bangor, Me.; T. J. Allen, of Shreveport, La.; A. T. Saball, of Jacksonville, Fla.; T. S. Hopkins, of Thomasville, Ga.; O. W. White, of Detroit; J. W. Parsons, of Portsmouth, N. H.; P. C. Remendino, of Santiago, Cal.; Thomas T. Minor, of Seatle, Washington Ter.; Chas. Denison, of Denver; H. C. Ghent, of Belton, Texas; E. P. Hurd, of Newburyport; E. W. Morley, of Cleveland; W. P. Hart, of Washington, Ark.; R. D. Webb, of Livingston, Ala.

Section of Military and Naval Surgery and Medicine.—There were added to the Council Drs. J. W. Hamilton, of Columbus, O.; J. H. Murphy, of St. Paul; W. C. B. Fifield, of Boston; E. Goodman, of Philadelphia; W. S. Tremaine, U. S. A.; J. H. Peabody, of Omaha; and S. T. Armstrong, of U. S. M. H. S. Dr. J. Mc F. Gaston, of Atlanta, was added as Secretary.

Section of Practical and Experimental Therapeutics.—Drs. Edward Curtis and Laurence Johnson, of New York, were stricken from the Council, and the following were added: Drs. G. Griswold, of New York; F. Stewart, of Cincinnati; J. M. Flint, U. S. N.; E. P. Fraser, of Portland, Oregon; W. G. Breck, of Springfield, Mass.; F. Woodbury, of Philadelphia; J. B. Van Velsas, of Yankton, Dakota; A. B. Tadlock, of Knoxville, Tenn.; J. F. Payne, of Galveston, Texas; T. Weed, of Cleveland;

Digitized by Google

D. W. C. Wade, of Holly, Mich.; R. C. Moore, of Omaha: G. M. Garland, of Boston; ——— Buddick, of Omaha: Wm. Compton, of Lancaster, Pa.

Section of Diseases of Children.—Dr. J. H. Ripley, of New York, was stricken from the Council, and the following were added: Drs. W. B. Atkinson, of Philadelphia; E. Walker, of Evansville, Ind.; W. A. Conklin, of Dayton, Iowa; W. F. Holt, of Macon, Ga.; G. K. Johnson, of Grand Rapids, Mich.; C. A. Leale, of New York; S. H. Charlton, of Seymour, Ind.; W. H. Doughty, of Augusta, Ga.; B. H. Riggs, of Selma, Ala.; H. H. Middlekamp, of Warrenton, Mo.; J. A. Hodge, of Henderson, Ky.; G. W. Moody, of Huron, Dakota; and A. A. Horner, of Helena, Ark. Dr. E. T. Williams, of Boston, was substituted for Dr. Thomas M. Rotch, of Boston, as Secretary.

PUBLIC OPINION ON THE INTERNATIONAL CONGRESS ORGANIZATION.—The action of the American Medical Association at New Orleans bids fair to jeopardize the success, if not the existence, of the Congress to be held in Washington in 1887.

The facts of the case, so far as we can learn, are as follows: At the Washington meeting of the American Medical Association, in 1884, a committee of seven was appointed by the President to "extend, on behalf of the medical profession of the United States, to the International Medical Congress, about to meet in Copenhagen, a cordial invitation to have the next International Medical Congress meet at Washington in 1887," and to this committee was given full power to add to their membership, and to perfect the organization. The invitation was tendered and accepted, and, as we understand it, the committee was entrusted by the Executive of the Copenhagen meeting with the care of organizing the next Congress. It became *de facto* a committee, not of the American Medical Association, but of the profession, deriving its existence from the International Congress, and no more responsible to the American Medical Association than to the American Academy of Medicine. In this way only is the organic continuity of these international congresses maintained; each executive appoints its successor, and the committee nominated at Copenhagen is the descendant of the committees which organized the previous meetings. Believing that it had full powers to act, the committee added eighteen or twenty members, chosen rather on professional than geographical grounds, and, at a meeting in November, appointed the officers of Congress and arranged the sections. A pamphlet, giving the details of organization, and a list of the officers of the various sections, was issued this spring, and widely distributed in Europe. At the New Orleans meeting, Dr. Billings reported progress on behalf of the Committee, but the Association expressed its decided condemnation of the work already done, and nominated thirty-eight additional members to take the place of those selected by the original committee of seven.

It is a great pity that Dr. Billings did not then and there assert the independence of the Committee, once having been entrusted with power from the Executive of the Copenhagen Congress. The additional thirty-eight men nominated by the Association may be representatives territorially, but certainly not of the profession, as were those nominated by the committee of seven. With the exception of eight or nine, they are unknown men. Among the officers who were appointed by the Committee are several prominent New York physicians, who, on the Code question, are not in harmony with the American Medical Association, and this seems to have been a special offence. Nothing illustrates more forcibly the necessity of the Executive of the Congress being absolutely independent of the Association; for, if controlled by it, there will be men of great prominence in the profession excluded from participation on account of this wretched Code quarrel—men who, if the Congress was in any other country, would be cordially welcomed. The new Committee has, we learn, decided to meet in Chicago at an early day, and it is to be hoped the members will see the false position in which the Association has placed them and quietly discharge themselves. It is for the original Committee now to determine whether the meeting in 1887 shall be under the wing of the American Medical Association, or whether it shall be truly an international gathering, managed and controlled by representatives of the medical profession of the United States. Upon their determination rests the success or failure of the Congress.

There can be no doubt, as the *New York Medical Journal* says, that the Association was forced into taking this action by some notorious wire-pullers, who were discontented at not having been placed in office. The presence of some of these men on the new Committee is the most objectionable feature about it, and will assuredly alienate the support and sympathy of the very men of the profession who are most needed to make the Congress a success. — *Canada Medical and Surgical Journal*, June, 1885.

When a complete record of the doings of the new Committee is obtained, it will be found that a more general selection has been made from all parts of the country, and yet without any lowering in the standard of the qualifications of those selected. . . . . It will thus appear that the work of the Committee, during its recent meeting, has been, as we predicted, highly conservative, and, for the most part, judicious.—*Journal of the American Medical Association.*

The new Committee proceeded to reconstruct the work of the original Committee in a radical manner. . . . . Many names of representative men, who are loyal to the Code, have been stricken off to make room for new names. . . . . "The axe is laid unto the root of the trees." Comments are in order. It is said that the wind is set from the east, and that we may expect a tempest, if not a tornado.—*Louisville Medical News.*

The preamble and resolutions adopted by our brethren in Philadelphia show plainly that the strong men of the profession in that city are not to be made the cat's paws of a little knot of agitators. It is significant that several of the names signed to the resolution are those of men appointed to high positions in the new list of officers of the Congress. . . . . We must confess that the outlook for the Congress is gloomy.—*New York Medical Journal.*

THE CHOLERA IN SPAIN.—A press cablegram states that the total number of new cases of cholera in Spain on Monday last was 1700 and of deaths from the disease, 797.

ORIGINAL LECTURES.

FLOATING KIDNEY.

A Clinical Lecture delivered before the Post-Graduate Class at the Jefferson Medical College.

BY JAMES C. WILSON, M.D.,
INSTRUCTOR IN PHYSICAL DIAGNOSIS AND ATTENDING PHYSICIAN AT THE HOSPITAL.

GENTLEMEN: I bespeak your attention to-day to a group of cases which are by no means the less interesting nor always the less difficult of diagnosis because they occupy the undefined border-land between health and disease. I refer to those cases in which the problem of diagnosis arises from actual displacement of the viscera. As compared with the number of patients suffering from positive disease which will come under your observation, the individuals subject to conditions of this kind will be few, indeed. And perhaps for this reason alone these conditions are especially worthy of your attention; just as comets, which are not always more conspicuous than the other heavenly bodies, especially interest astronomers by reason of the infrequency of their occurrence as well as by reason of the eccentricity of their orbits. But these comparatively rare conditions are not only often difficult of diagnosis, they also frequently occasion serious secondary lesions, and the gravest consequences to health.

In general terms, displacement of the organs of the body—aside from such changes of position as are secondary to pathological processes in adjacent parts—may be referred to two principal groups. First, those due to some departure from the usual order of development. This is seen in hetero-taxia, where lateral transposition of one or more or of all the organs may occur. To this group are also to be referred those cases in which the testes are permanently retained in the cavity of the abdomen—cryptorchidism; and second, that group of cases in which organs have become dislocated in consequence of the relaxation or giving way of the normal tissues of support. This group includes (*a*) herniæ of all kinds, in which there is local failure of the walls of cavities conjoined with elongation of those anatomical reflexions of tissue which form the visceral ligaments, and (*b*) cases of the latter lesion alone, whereby certain of the viscera are permitted not only to depart from their normal sites under the influence of gravity and various pressures, but also to move more or less freely around, and hence come to be termed movable or floating organs.

Owing to their peculiar anatomical relations, the kidneys are of all the organs the most liable to this form of displacement, and I am fortunate in being able to present to you for examination this patient who has been for some time under my observation, and who presents for your study an excellent example of the condition known as movable or floating kidney.

The patient who has been before my classes on previous occasions, is aware of the character of her trouble, good-natured and intelligent; moreover, her general health is, in consequence of treatment which we have advised, much better than for a long time, and she submits willingly to such manipulations as are necessary to demonstrate to you the physical signs of her abnormal condition.

She is a married woman, 35 years of age, the mother of seven children, of whom the youngest is two and a half years old. Shortly after the birth of her last child she noticed on the right side of the abdomen near the median line and above the level of the umbilicus an oblong, regular, slightly crescentic tumor, measuring in its vertical diameter about six inches, in its lateral diameter about two inches and a half. This tumor, the outline of which can be distinctly felt through the relaxed abdominal walls, is of moderately firm consistence and somewhat tender upon manipulation. Its concavity presents toward the median line and backward. It is freely movable within certain limits, and can be displaced an inch or more toward the right and as far toward the left as the median line. In the erect posture it occupies a position somewhat lower than that which it assumes when the patient lies upon her back. In the latter posture it is possible by gentle manipulation and pressure upward and backward to cause the tumor wholly to disappear, only, however, to become again evident when the patient assumes the erect position. Physical examination reveals no pathological enlargement or displacement of the organs of the body commonly accessible to this method of investigation. Percussion, however, in the lumbar region near the spine elicits upon the right side a percussion note somewhat more resonant than that of the corresponding region upon the left side. Inspection and, still more satisfactorily, palpation indicate slight flattening of the right side in this region as compared with the left. Upon causing the tumor to disappear as above described, all these physical signs vanish. Light percussion over the tumor elicits dulness, more forcible percussion tympanitic resonance analogous to, but less intense than that elsewhere over the abdomen. Careful chemical and microscopical examinations of the urine on several occasions have established the fact that there is no disease of the kidneys. For the rest, as I have already stated, this woman's health is at present fairly good, much better than for several years, and the presence of this tumor no longer occasions the physical distress and mental anxiety that it formerly did. The explanation of this important change in the patient's symptoms bears directly upon the etiology and general management of such cases. Some months ago her health reached the lowest point in a life of unremitting hard work and rapid childbearing. She was anæmic, weak, much troubled with vague and with definite pains, the latter being constantly present in the back and pelvis, and accompanied with a constant sense of tension and pressure. Pains of a dragging and teasing character were

Digitized by Google

associated with the presence of the tumor, itself a constant source of anxiety, its nature being then unknown to her. She suffered also from abundant leucorrhœa and a tormenting frequent desire to pass urine. The tumor was at that time almost constantly present, and if it disappeared upon assuming the recumbent posture or under the manipulations of our examination, it was only for a brief time. Not only is her general health much improved in all respects, as you perceive, but the tumor itself as she tells us, is no longer a source of mental anxiety to her, nor, indeed, of any very great physical suffering. Nay, more, she assures us that it can be caused to disappear for long periods, and on one occasion recently was not present for three weeks. It is, however, apt to reappear upon efforts of lifting and particularly in carrying heavy weights up stairs.

Her improved physical condition is due to the fact that an important uterine lesion, the real cause of her more serious symptoms, was at that time discovered and relieved by operative measures. This lesion consisted in extensive bilateral laceration of the neck of the uterus with marked ectropion of the cervical mucous membrane and hypertrophy. The operation was performed by Dr. C. M. Wilson, at the Nurses' Home, and was in every respect a complete success. The patient was kept upon her back for three weeks and was treated with small doses of strychnia in Basham's mixture, having at the same time a generous and wholesome diet. In the course of time the anæmia, the feebleness, the general and localized pains, the leucorrhœa ceased, and the condition of the patient is, she declares, now better than it has been for several years.

The disposition on the part of the kidney to retain its normal place is due to the higher position of the uterus since the operation, and to the improved tonicity of the abdominal walls, which the general improvement in health has brought about.

With this improvement of her physical condition, there has been a remarkable gain in the patient's mental state. The removal of the thorn in the flesh, the three weeks' rest in bed without toil, without anxiety, with plentiful food, did much for her. Moreover, her mind is at rest concerning the nature of the tumor, which she now knows is not, as she formerly feared, a cancer.

Movable kidney may be congenital or acquired. When congenital, it is due to the anatomical anomaly of elongated renal vessels and the existence of a mesonephron. When acquired, the absorption of the encapsulating fat resulting from acute or chronic sickness, congenital laxness of the posterior peritoneum and relaxation of the abdominal walls, such as is usually present in women who have borne several children, must be looked upon as favoring causes. The much greater frequency of movable kidney among the laboring classes gives color to the supposition that the lifting and carrying of heavy weights tend to establish the condition in individuals otherwise predisposed to it. Movable kidney is far more frequent in females than in males, the proportion being six to one. It has been observed in childhood and adolescence, but the greater number of cases occur in women during the childbearing period. The right kidney is displaced much more frequently than the left, the proportion being nearly five to one, and less frequently both kidneys are displaced. The displaced kidney is not necessarily altered in structure, but may be affected by malignant, fatty, or other degeneration. It is movable in the segments of circles of which the radii correspond to the length of the renal vessels, but it occasionally happens that in consequence of local peritonitis, it contracts adhesions to contiguous organs and becomes fixed. When the abdominal walls are sufficiently thin palpation reveals the characteristic renal outline of the tumor, and, in some instances, the pulsation of the renal artery has been detected. The difficulties of diagnosis presented by a kidney only slightly displaced, or in individuals with thick abdominal walls, are sometimes very great. The outline of the tumor is usually greater than that of the normal kidney, a fact readily explained in the absence of actual enlargement of the organ by its being invested by the posterior layer of the peritoneum and the subserous connective tissue. The most common symptoms are a sense of weight or dragging in the position of the tumor, to which are often added dull, radiating, neuralgic or colicky pains, all aggravated by movement and exercise. Dyspeptic symptoms are also commonly present, and nausea is by no means rare. Mental depression and anxiety, as has already been pointed out, are frequent and important symptoms.

The prognosis as regards life is favorable, as regards permanent relief, unsatisfactory.

The treatment, by a sort of contradiction of terms, is more satisfactory than the prognosis, for while you cannot relieve the condition, you can do much to make it bearable. In the first place, you must make your patient understand the nature and character of the tumor, in order to relieve his mental symptoms; in the second place, associated causes of ill-health must be removed. The patient before you affords a striking illustration of the importance of this course. As anæmia and inanition are very frequently present, a generous diet and the use of iron are indicated. As the subjects of this condition are frequently overworked as well as underfed, rest and the avoidance of the more toilsome occupations are, if possible, to be secured. You will find in your text-books abdominal bandages, variously padded, recommended to secure the kidney in its position, an object in which for the most part they utterly fail. If the symptoms be such as to wear the patient out and to incapacitate him for self-support and enjoyment of life, or if the displaced organ be the seat of malignant or suppurative disease, surgical interference may become necessary. In the former case, whether the displaced organ, free from disease, should be extirpated—nephrectomy—or fixed in the loin—nephrorrhaphy—is still an open question in surgery. In the latter case, extirpation is the only resource, and nephrectomy is, as you know, even under favorable circumstances, one of the most fatal operations of surgery.

EXENTERATION OF THE EYE: A SUBSTITUTE FOR ENUCLEATION.

BY MIDDLETON MICHEL, M.D.,
OF CHARLESTON S. C.

THE memoranda of a case of shot-wound of the eye recently under my care, furnish on this occasion some reflections on a method of operation that

Digitized by Google

promises perhaps better results in the future, than the more destructive procedure of enucleation always resorted to at present as the surest means of preventing sympathetic ophthalmia.

The introduction of enucleation into ophthalmic surgery secured, it is true, a very certain arrest of all irritative and destructive sympathetic radiation that otherwise sooner or later inevitably compromise the sound eye; but it has also served to impress us with certain dangers of possible recurrence with which we are familiar, who have often practised this operation. Indeed extension of inflammatory action to the meninges, and even death, that have sometimes taken place consequent upon this operation, explain the anxious solicitude and brilliant anticipations expressed on every hand when first we heard of optico-ciliary neurotomy as a substitute for enucleation; and the regret subsequently experienced when even this method failed to realize all that was promised in its behalf. Not that we mean to imply that enucleation must not indeed be always performed in malignant disease, but simply that for the single object of cutting off. sympathetic communication with the sound eye when the lost one becomes the source of irritation, some less disfiguring yet equally effective operation might be devised.

It is only within a few months that an attempt has been made to destroy all neural connection with the sound eye by removal of the injured organ without opening the capsule of Tenon; without involvement of the orbital cellular tissue, yet still retaining the sclera with its several muscles as a movable stump for subsequent support of an artificial eye.

Such an operation within the few past months has been executed in Hall, and in England, and by myself a few weeks since.

While it may be predicated of this new operation that it is wholly exempt of danger to life, still the few cases recorded so far are only presumptive evidence that it is destined to fulfil all the requirements and indications of a successful operative procedure. The complete destruction of the peripheral relations of long or short ciliaries and optic nerves; the obliteration of bulb by removal of its contents; the uninjured capsules of Tenon and Bonnet; the non-invasion of subconjunctival tissue; in other words, an untouched orbital cavity, yet an eye thoroughly removed, are the salient conditions of a procedure that seems to foreshadow the speediest cure and surest results.

This simple method consists in opening the eye just beyond the sclero corneal border, as in the operation for staphyloma, finishing the abscission of the anterior segment of the bulb with scissors, then with scoop or curette, introduced between choroid and sclera, enucleating the contents of the globe, eviscerating the organ so as to destroy completely all ciliary and optic connection with the sclerotic, arresting hemorrhage, and cleansing the sense-capsule with cotton compresses dipped in a weak solution of corrosive sublimate, then suturing the scleral cup with two or three catgut ligatures, all of which is conducted under a continued antiseptic spray of corrosive sublimate.

So far as the encheiresis involved in this method of operating is concerned, contrasted with enucleation or optico-ciliary neurotomy, the preference, even in the hands of an expert, would seem to be in favor of exenteration or evisceration; but it remains to be ascertained whether the healing process will always be rapid and unattended with any complications. I have had but a single opportunity of testing the results of exenteration which occurred recently, and I will now relate the case:

Isaac S., white, aged 20 years, native of Hamburg, residing in Summerville, S. C., came to me April 3, 1885. Shot in the right eye by a robber who waylaid him in Summerville on the night of the 2d April, the eye became immediately swollen and dreadfully painful. The next morning, the pain being still more severe, and discovering that sight was gone, that not even perception of light remained, he was brought to the city, and being a Jew, he applied as a stranger to the Hebrew Benevolent Society for instruction, and he was sent to me by letter from the President, Mr. M. Triest. He was taken to a private boarding house, and every arrangement made to operate upon him the next day, as he was informed that his eye was lost and would have to be removed lest it should induce sympathetic irritation in the other eye.

Present Condition.—Right eye and eyelids very much inflamed, painful, swollen, ecchymosed; eye black and blue, the effusion of blood extended to the cellular tissue of the face around the orbit. No fracture of bones about the orbit, no emphysema, no wound of the integument about the face or eyelids. A penetrating wound of the cornea, through which a bead of aqueous appeared as often as it was wiped away, was already surrounded by a zone of effused lymph, and occupied the ciliary border. Through the nebulous cornea the pupil irregularly dilated could just be discerned. In the lower and outer half of anterior chamber a white deposit was seen, to which the iris was attached, resembling a hypopyon of some duration. The aqueous was sufficiently clear to permit a view of the iris and pupil, but from the fundus we obtained no reflex, for the vitreous seemed the seat of intraocular hemorrhage, and T. was + 1, which obscured the fundus and interdicted the discovery of any foreign body like a shot. Steady increase of pain and inflammation since Wednesday, the day of the accident; position of the corneal wound near ciliary zone; accompanying chemosis of both lids and ocular conjunctiva; and the loss of nearly all light perception, proved that the eye was irrecoverably lost, either from penetration of a spent shot lodged in some part of the organ, or from laceration of cornea from the same source, consorted with concussion. There were already synechia and atresia of pupil that threatened painful iritic and cyclitic complications at no very distant period, conducting inevitably under these circumstances to monocular destruction and most probably to sympathetic ophthalmia. For these reasons, to save the sound eye and abridge the duration of cure, and his detention in the city, we advised immediate surgical interference, which he requested me at once to undertake.

Exenteration was performed the next morning,

Digitized by Google

April 4th. Desirous of testing the efficacy of hydrochlorate of cocaine in an operation of this character, as I had obtained most satisfactory results from its employment in minor operations, instillations of a few drops of a solution of one grain to the drachm, were made to the whole surface of the eye at intervals of three minutes or more for over twenty minutes until local anæsthesia seemed fully induced. The pressure of the speculum upon the œdematous and chemotic lids was, however, not unattended with inconvenience; and after the first steps of the operation through superficial parts were seemingly unfelt, such undisguised pain ensued as we progressed, that we had to suspend the operation and resort to ether to secure the best results for this new procedure. Under a continuous spray of corrosive sublimate solution 1 to 4000, with fixation forceps, keratome, and scissors, abscission of the front of the eye was readily accomplished, when with a vulcanite scoop passed by a to-and-fro movement between the choroid and sclerotic to the fundus evisceration followed, aided by curette and scissors, not without some difficulty, especially in detaching the retina from the canalis opticus.

The vitreous was discolored by extravasated blood, and more hemorrhage occurred from the fundus than I had expected. In the hemorrhagic contents removed, I sought in vain for any trace of shot, which shows how difficult, even impossible, it often is to say whether the foreign body has penetrated the eye. After cleansing the sclerotic cup this was closed by three sutures, and formed an excellent stump. With the exception of soreness, by the next day all circumorbital pain subsided, and although a very considerable chemosis subsequently occurred, protruding the tarsal cartilages and everting both lids, this condition was relieved by free scarification. Cooling applications of lead lotion were substituted now for Warlemont's wash, which had been applied previously to allay the ciliary neurosis and orbital pains with which he had previously suffered.

In staphylomatous eyes, recovery from enucleation is more rapid than from abscission, for in the latter case we leave a scleral cup containing such elements (as choroid, retina, and vitreous) that undergo retrogressive changes, sometimes of a destructive nature even should no suppuration occur; but after exenteration the empty sense-capsule, with no structural element likely to take on inflammation, is supposed to heal with rapidity, as cures are said to occur in two days. I was disappointed to find in my case that this was delayed for two weeks, with no elevation of temperature or pain, but with some secretion of a muco-purulent discharge, though very slight. I am disposed to refer this delay to damage done by the accident and to the extraordinary chemosis that occurred in consequence of the deferred operation. It is possible that had exenteration been immediately performed, convalescence would have ensued in two or three days, for, after scarifying the conjunctiva, the subsidence and defervescence that followed showed the cicatrix of a wound, that, from its firm and insensitive nature, must have been for some time healed.

The superiority of this new operation for cosmetic purposes is apparent in the symmetry of a prominent and rounded stump, moved by each and every one of its muscles in harmony with the other eye, furnishing a solid support for the glass eye.

Enucleation, on the contrary, entails a permanent deformity upon the sufferer, since the empty orbit offers no longer any support to the eyelids, which, falling in, are no longer able to conduct the tears to the puncta, this secretion becoming a source of constant irritation unless the lachrymal gland be also excised.

Again, an irremediable symblepharon often results from cicatricial contractions that interdicts the possible introduction or retention of an artificial eye, a condition that has too often embarrassed our efforts to give this a proper support.

Among the greatest advantages of the new operation, however, is the pleasing assurance that not having opened any of the intravaginal lymph spaces of the orbit, no traumatic pathway obtains for the conduction of morbid products to the meninges or to the brain.

Since the writing out of this case, enabled as I have unexpectedly been to perform another exenteration and this before the members of this Association in session, I shall here detail the additional operation which they witnessed and its results, as constituting, so to speak, a part of our proceedings:

Charlotte C., negro, of about 50 years, domestic, native of this city, living in Henrietta Street, was sent to me April 22, 1885, with a disorganized globe, from a blow of splintered wood. She was cutting wood with an axe, when a splintered fragment flew up, striking her in the right eye. This occurred three weeks ago. On receipt of the injury the sight was immediately lost, and since its occurrence she has had no rest, no ease from the constant pain in orbit, and around the eye, even along the region of the temple. Her sufferings have not diminished, but are increased when she is in the recumbent position. The other eye is now so "weak" that she cannot look at an object without its "watering" so much so that her sight is obscured. She thinks the "sight must be gone in the injured eye, as she cannot see with this eye, not even light." She says "her good doctor has been doing everything for her; putting drops into her eye, but they have done her no good," and she wants me "to take out the eye," which she knows "will ease her, just as if you took a rotten tooth out of her head." This we promised to do to-morrow.

Present Condition.—Phthisis bulbi of right eye. Cornea exhibits a deep leucoma occupying its lower half, iris attached, pupil nearly obliterated and discolored; sclerotic intensely congested; globe prominent and tense, painful on pressure, V = 0; circumocular chemosis; epiphora; orbital and temporal neuralgia.

Operation was performed April 23d, before members of the Association, at 12 o'clock. Exenteration was again followed by considerable bleeding as in my previous case, controlled by lint and ice. Chloroform was administered, sclera sutured, and cold compresses applied. Globe was found disorganized

Digitized by Google

by lymph deposits, and iris adherent to cornea in part.

April 24.—Pain has greatly disappeared, though still sufficient to disturb her rest. No appetite, temperature normal, no discharges on dressing; cold compresses to be continued.

25th—Condition the same. Œdema about upper lid. Considerable serous chemosis. Scarified conjunctiva freely. Compresses dipped in Goulard's lotion and tr. opii continuously applied.

26th.—Œdema of upper lid considerable. Chemosis so great that it projects entirely out of orbit; scarified again.

28th.—No pain whatsoever, up and moving about. Scarifying has not notably subdued the swollen conjunctiva.

30th.—Lid less swollen. Chemosis slowly receding. Lotion continued.

May 7.—To-day two weeks chemosis considerable; no apparent inconvenience from exposure of protruded conjunctiva to dust and air.

13th.—Turgescence of mucus much decreased, though still sufficient to conceal the sutures, which, after search, were found firmly attached to a remarkably bulbous sclerotica, that had by no means collapsed; the plica semilunaris projects, discolored at inner canthus. On drawing upon these sutures a prominent and resistant bulb, T = 2, still readily determined by the touch, showing that, as yet, no shrinkage to any perceptible degree, has occurred, though this is three weeks since the operation. Pressure on upper eyelid when closed discovers the globe very easily, as it moves in different directions drawn by the muscles. The sutures were removed to-day.

A feature of constant attendance upon these two operations was the remarkable chemosis ensuing within a few days, so considerable that the conjunctiva bulbi protruded entirely beyond the palpebral fissure, completely burying the lower lid, and concealing all trace of the sutured bulb. This condition, together with an extensive œdema of upper lid, gives an unusual aspect to these cases, unlike what is seen in any other operation upon the eye.

Unattended by any kind of discharge, pain, or elevation of temperature, that would liken this appearance to an aggravated form of purulent ophthalmia in infants, I am disposed to regard the occurrence as peculiarly characteristic of the operation of exenteration; so much so that were I in presence of an œdematous upper lid, beneath which projected a conjunctival intumescence of considerable size, constricted, as it were strangled, at the palpebral fissure, without reactionary process, and without discharge, I should feel no hesitancy in declaring that the eye had been eviscerated.

This repeated occurrence of so exaggerated a chemosis arrests attention, and is suggestive of a perfect explanation, even demonstrative of the whole subject of conjunctival connections and actions.

Chemosis is not always the declaration of hyperæmia. In the instances before us the chemosis is a serous, not a vascular, infiltration of the conjunctiva; consequently is void of inflammatory heat, of pain, or of the purulent or muco-purulent products of inflammation; it is a simple infiltration of serosity beneath the loose, serous, cellular tissue of the ocular conjunctiva, the aponeurotic arrangements of whose retrotarsal folds retain the hypersecretion within the anatomical limitations of this part of the orbit, free to move extraorbitally to an almost unlimited extent, but checked in any retrogressive tendency towards the orbital cavity by the firm orbital fascia in this region.

In such an unsightly turgescence there is, then, no indication of alarm, no threatening of danger.

But, why should this excessive chemotic œdema occur after exenteration? is the question proposed by those who witnessed this phenomenon twice thus regularly produced—a phenomenon differing essentially from the partial and asymmetrical swelling of the conjunctiva from other surgical interferences upon the globe.

This question seems of interest sufficient to call for the reply that suggests itself at this juncture. When we recollect the importance of shape and dimensions to the eye as a dioptrical apparatus, where the slightest deviation, even of a fraction of a line, must of necessity vary its optical focus, one will fully appreciate the axiomatic truth, that *the eyeball never changes its form.* For the maintenance of this physiological condition a normal tension of the eyeball is recognized, and an equable pressure in its vicinage, and throughout the whole orbit is of paramount importance; but, when this pressure is suddenly and greatly disturbed, indeed wholly abolished by emptying completely the entire ball; the great change that immediately ensues in the perioocular circulation explains the passive effusion which commences at once, which, independent of all reactionary influences of an inflammatory nature, finds its readiest vent beneath the serous cellular tissue of the preorbital region. This sudden abolition of all ocular tension, the obvious result of gutting the eyeball, produces, mechanically, a greater filling of all the orbital vessels in vacuo; and this leads, perhaps, to the chemosis that so rapidly ensues.

Whatever be the proper explanation of this occurrence, however, it certainly is the most remarkable feature as a sequel to this operation. Nor does it rapidly disappear, since in my first case it took two weeks to subside; and in the second case, now under consideration, being the third week of the operation, it has by no means vanished. I do not, therefore, understand how cures have been reported to have occurred within two or three days.

Another point is the hemorrhage that persists for awhile after evisceration is completed; welling up from the empty sclerotic to an extent far beyond what I could have supposed probable, from the severance of such inconspicuous vessels as the central artery of retina and ciliaries. Yet, here again we must find an explanation in the anatomical peculiarities of the part. These vessels, however small they be, perforate an inextensible fibrous capsule, and, while imprisoned within their fibrous attachments to the sclerotic, are held patent and unable to retract. Trifling as this circumstance may seem, when applied to such minute vessels, yet in other situations in the body we know it to be often of

Digitized by Google

great import if not controlled by pressure, and even by the application of ice, to both of which we had recourse on these occasions, to avoid a loss of blood out of all proportion to the simple nature of the operation.

Again, another question connected with this procedure is, What becomes ultimately of the emptied sclera? Will it really constitute the prominent and permanent support for prothesis, which is claimed for it? Or does it collapse, and, through shrinkage, become atrophied? These are questions that remain to be determined in the future. So far as my personal experience extends, which is at present six weeks since operating upon Case I., I have discovered that a globular mass remains, exhibiting a healthy non-vascular sclerotica of remarkable firmness, that rolls under pressure like the ball itself, turned by its muscles as each is called into action, strikingly resembling the bulb in all its entirety.

It is possible that the sclerotica, still nourished by its proper vessels, pours out exudates that subsequently become, through fibrillation, an organized body of fibrous structure, but little smaller than the normal globe, that long will exist as a firm, well-nourished stump, sustaining the lids in proper relation to the tear passages, since we have ascertained that this secretion reaches the puncta safely, and that none overflows the cheek in the case referred to.

In the gunshot injury above detailed, as no shot was detected, we see that phthisis bulbi resulted from simply a glance shot that incised the cornea, and produced destruction of the eye by concussion, lodging neither within the organ itself nor within the orbit; but, falling short of this, should a shot become buried in the orbital cushion of fat, harm would not necessarily result. Inflammatory processes of the orbit are not of common occurrence. Sympathia never originates but from ciliary or optic sources. We see foreign bodies of extraordinary nature retained indefinitely in the vicinage of the bulbus oculi, encapsulated in the fat cushion, without giving pain to the subject, who remains even unconscious of their presence.

We could rehearse many instances of this kind, but will recall only two that are memorably known to all oculists:

The first is Clarke's case, recounted by Carter, of Stroud, in which piece of a hat-peg of cast-iron, "measuring three inches and three-tenths in length, and weighing twenty-five scruples," was extracted from the orbit of an old man of seventy-three years of age, after a period of impaction of not less than ten, and probably even twenty, days,—the man recovering without a bad symptom.

The second is the Nélaton and Desmarres's yet more famous case, in which the former surgeon removed from the orbit the broken-off ivory handle of an umbrella that had lain embedded therein for three years unknown to the young man himself, and to the celebrated oculist Desmarres, who failed to discover any foreign body at the time of the accident, though the ivory handle measured "one inch and five-eighths in length, and half of an inch in thickness." This patient also left the hospital with "vision improved, and with the fistula nearly healed."

A small shot that has impinged upon, or that has even traversed the eyeball, may therefore safely remain embedded in the deeper parts of the orbit with little trouble; but, should symptoms of *sympathia* arise, this circumstance would in nowise interdict the operation of exenteration.

These, then, are some points of interest suggested by this novel operation of exenterating or eviscerating the eye, that have induced me to bring before your notice a modified surgical procedure in ophthalmology but little known as yet even to specialists.

DISINFECTANTS.

PRELIMINARY REPORTS OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

XIII.

DISINFECTION WITH MINERAL ACIDS.

BY VICTOR C. VAUGHAN, M.D., PH.D.,
PROFESSOR OF PHYSIOLOGICAL CHEMISTRY IN THE UNIVERSITY OF MICHIGAN.

DISINFECTION with mineral acids in one form or another, has long been practised. Sulphurous acid was used by the ancient Greeks in the purification of their temples after sacrificial offerings had been made. In 1773, Morveau recommended the vapor of hydrochloric acid produced by the action of sulphuric acid on sodium chloride. In 1780, Smyth began the use of nitrous acid vapor as a disinfectant. During the present century, many experiments have been made for the purpose of determining the value of the mineral acids as disinfectants, both in liquid and in vapor form. It is the purpose of this paper to review briefly these reports, and to ascertain what conclusions may be drawn therefrom. Since sulphurous acid has already been discussed in this connection, no further mention will be made of it here.[1]

Hydrochloric acid.—Dougal[2] found that vaccine virus exposed under a bell-jar of a cubic foot capacity, for twenty-four hours, to the vapor of the acid became inert. After exposure, the lymph was mixed with glycerine and water, and the reaction of the mixture (acid) was noted. The mixture was then hermetically sealed in tubes, and so kept until used. Dr. Dougal believed that the effectiveness of the vapor was due to its rendering the virus acid. In proof of this he gives the following tabular statement of the reaction of the lymph and glycerine mixture used in his successful and unsuccessful vaccinations after exposure to different agents:

Successful vaccination. Virus not destroyed.	Reaction of the lymph and glycerine mixture.	Vaccination not successful. Virus destroyed.	Reaction of the lymph and glycerine mixture.
Carbolic acid vapor.	Neutral.	Chloride of lime.	Acid.
Carbolic acid.	"	Sulphurous acid.	"
Chloroform.	Alkaline.	Nitrous acid.	"
Camphor.	"	Glacial acetic acid.	"
Sulphuric ether.	"	Hydrochloric acid.	"
Iodine.	Neutral.		

[1] THE MEDICAL NEWS, March 28, 1885.
[2] Glasgow Med. Journal, vol. 5, p. 166.

Digitized by Google

Commenting upon the above table, Dr. Dougal states: "These results *per se* are singularly and suggestively explicit. They show that the mixture of lymph and glycerine of the successful vaccinations was either neutral or alkaline; while that of the unsuccessful was, without exception, acid. Hence, volatile acids, or a volatile body causing acidity by chemical affinity, as the chlorine from the chloride of lime, which produces hydrochloric acid and free oxygen, are the best destructives of the active properties of vaccine lymph, and therefore *a priori* of variolous matter and other zymotica.[1] The same theory is insisted upon by Dr. Dougal in a later paper.[2] Results with hydrochloric acid vapor similar to those obtained by Dougal, were reached by Braidwood and Vacher in eight experiments.[3]

Koch[4] ascertained by cultivation that anthrax spores were destroyed after ten days' exposure to a two per cent. solution of the acid; but that exposure for from one to five days failed to destroy the spores.

Dr. Sternberg, in some experiments made for this report, found hydrochloric acid to fail as a disinfectant when used in the ten per cent. solution, and to be successful when the strength was increased to fifteen per cent. Each c.c. of the acid used by Dr. Sternberg contained 0.395 grain of HCl.

Sulphuric acid.—Koch[5] noticed diminished development of anthrax spores after exposure to a one per cent. solution of sulphuric acid for twenty days. The test was by cultivation. Salmon,[6] experimenting upon the micrococcus of fowl cholera, found one-half per cent. solution of sulphuric acid successful as a disinfectant, tested by inoculation; but one-fourth and one-eighth per cent. solutions unsuccessful, tested by cultivation. Sternberg[7] states that "sulphuric acid destroys B. termo and the two species of micrococcus experimented upon in the proportion of 1 : 200; but a four per cent. solution failed to destroy the bacteria in broken-down beef tea (old stock), doubtless because of the presence of reproductive spores. The multiplication of the bacteria mentioned was prevented by the presence of this acid in a culture solution of 1 : 800." Dr. Sternberg has given the per cent. of sulphuric acid necessary to insure disinfection at eight. Each c.c. of the acid used contained 1.480 gramme H_2SO_4.

Nitrous acid. - Dougal[8] found that vaccine lymph exposed to nitrous acid under a bell-jar of one cubic foot capacity for twenty-four hours, was rendered inert. The lymph was treated as given under hydrochloric acid, and the action was supposed to be due to rendering the lymph acid.

Notler[1] has experimented upon nitrous acid as an aërial disinfectant. However, his conclusions are not wholly trustworthy, as he considered the bacteria destroyed when their motion was only arrested. He says: "I believe the full effect of the agent to be produced when there is arrest of motion, with complete precipitation and disorganization of the bacteria, and I have endeavored in each case to look for this result." One hundred c.c. of putrid beef infusion in saucers was placed in a chamber, of a cubic capacity of fifty-three feet, with two ounces of copper wire, and fifty c.c. of concentrated nitric acid, yielding 0.35 per cent. of nitrous acid. Soon the bacteria became less active, and in forty-eight hours the activity was still further diminished, and a heavy precipitation of the organisms was noticed. The infusion was free from odor. On the third day, there was no tendency to the further development of bacteria and the liquid was quite inodorous. At the end of a week there was no further decomposition and the infusion was found to be strongly acid.

Sternberg[2] found that exposure of vaccine virus for six hours to an atmosphere containing one per cent. of nitrous acid vapor, destroyed the germs; also that the bacteria of putrid urine were destroyed when exposed on filter paper for six hours to an atmosphere containing one-half per cent. of nitrous acid gas.

Nitric acid.—Dr. Sternberg has ascertained that nitric acid fails as a disinfectant in solutions of five per cent.; but is effectual in solutions of eight per cent. Each c.c. of the acid used contained 0.819 gramme of HNO_3.

Chromic acid.—Koch[3] ascertained that anthrax spores were destroyed by exposure to one per cent. solutions of chromic acid after from one to two days.

Osmic acid.—Koch[4] found by cultivation that anthrax spores were destroyed by exposure for twenty-four hours to one per cent. of osmic acid.

Practical considerations of the use of the mineral acids as disinfectants. The action of ten and five per cent. solutions of sulphuric, nitric and hydrochloric acids upon lead pipes was tried with the results given in the accompanying table. Weighed pieces of lead pipe were placed in the dilute acids, and the loss was determined by subsequent weighings. This represents a more powerful action than

would result simply from the rapid passage of the disinfectant through the pipes; but the table gives results which would be obtained by the solution standing in a trap. At the time of each weighing, the dilute acid was replaced by a fresh portion.

The experiments were continued until the nitric acid had completely destroyed the pipe; but as the results are sufficiently shown by the above figures, it is unnecessary to give the table in full. After a number of days there was a slight increase in the weight of the pipes placed in the sulphuric acid solutions. All the acids used were of the commercial grade. We also have figures showing the action of the dilute acids upon iron pipes; but as this action is rapidly destructive with all the acids, it is unnecessary to give the figures. In order of disintegrating effect upon iron pipes, sulphuric acid acts with most vigor; while there is not much difference in the effects produced by the same strength solutions of nitric and hydrochloric acids. The action upon zinc is in the same order as that given for iron; while the solvent action of nitric acid on tin was found to be greater than that of either sulphuric or hydrochloric acid.

CASE OF ANOSMIA

ASSOCIATED WITH BONY STENOSIS OF VOMER WITH CONTRACTED INFERIOR MEATUS OF THE NOSE; OPERATION BY DRILLING, FOLLOWED BY IMPROVEMENT IN SMELL.

BY FRANCIS L. PARKER, M.D.,
PROFESSOR OF ANATOMY AND CLINICAL LECTURER ON DISEASES OF THE EYE AND EAR, MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA.

MR. T., aged twenty-five years, grocer, applied to me on the 7th of September, 1884, complaining of loss of smell in both nostrils. He was in good health, is married, and has several children, all of whom are healthy. He stated that for several years his chief occupation in the grocery business was in testing and classifying cargoes of bacon, much of which was rancid.

In July he had gone north on a pleasure trip and had spent the month in the White Mountains. He had not previously experienced any difficulty in the sense of smell. He returned and resumed his occupation about the first of August, and soon afterwards had examined and assorted a large lot of very bad bacon. Soon afterwards he noticed that the sense of smell was gradually lessening, and in the course of the month he could not detect odors of any kind. On some days smell would be present and last for a few moments, and not come back during the day. Sometimes it would last an hour in the morning entirely disappear for hours, and again return in the afternoon for a few moments; at other times, a day or two would pass without his being able to detect smell of any kind.

Upon examination I found some general congestion, and slight thickening of the mucous membrane of the nasal cavities on both sides. On the right side the meatus was somewhat contracted, but did not prevent a free circulation of air. On the left side there was a bony osteosis of the vomer infringing upon the inferior turbinated bone, and practically closing the inferior meatus; the middle meatus was larger than usual, and the superior was of normal size. There seemed to be no interference with the current of air on this side. The patient breathed as freely on this side as on the other.

Supposing the case of idiopathic origin, the sulphate of strychnia in doses of one thirty-second of a grain, with five grains of muriate of ammonia, three times a day was ordered, with directions to suspend his occupation as meat tester. The nasal cavities were also daily sprayed with the saturated solution of borax, and afterwards with a solution of iodine, iodide of potassium, and glycerine, with the view of relieving the congestion of the mucous membrane. This course of treatment was kept up till the 17th of September, with little or no improvement. Being about to leave the city for a month, the dose of strychnia was increased to one twenty-fourth of a grain.

I did not see the patient again till the 17th of October. He had continued his medicine regularly till the 1st of October without material change in his smelling, and for the past sixteen days he had stopped it. He stated that during the month smell had occasionally returned about midday for a short time and then "went off." Sometimes he could smell on one side and not on the other, and sometimes both sides "worked well." I had frequent opportunities to test the correctness of this statement. On the 15th it was good and lasted all the morning, Thursday it disappeared; Friday (to-day), it was present early in the morning and lasted two hours. At my office at 2 P. M. he could smell hartshorn, but not chloroform or iodoform. Strychnia in doses of one twenty-fourth of a grain, and with five grains of ammonia, was resumed three times daily, and electricity was applied every second day, for five minutes at a sitting, one pole being applied to the superior and middle turbinated bones. The cavities were also sprayed with solution of borax or soda bicarb., and iodine in some of the varied formulas recommended, was applied either by spraying or by the probe with cotton.

Oct. 30.—No perceptible change; smell returns irregularly as before, sometimes lasting one or two hours, or it may be only momentary. Same treatment continued, and I occasionally I gave him sittings of ten minutes in using electricity; it only tired his endurance without doing good.

Nov. 2.—Yesterday smell lasted six hours and seemed normal, he could detect all kind of odors; it left after dinner, did not return till breakfast to-day, merely momentary.

From the 13th to the 30th of November, there seemed to be gradual though variable improvement, he was worse when he took cold in the head.

Dec. 5.—No practical improvement, previous treatment stopped: suspecting that latent specific causes might be at the bottom of the difficulty, the patient was now put upon a course of mercury and iodide of potassium in the usual doses for a month without any notable change in his symptoms. Notes of the case would apply equally as well for the seventh of September, 1884, as for the first of January, 1885.

Digitized by Google

During January, February, and to the middle of March, being sick myself, treatment was practically suspended, except that the patient was directed to keep the nasal passages dilated with a solution of iodine, iodide of potassium, and glycerine, passed up with a probe armed with absorbent cotton.

On April 1st, his condition was practically unchanged, I had often suggested to him the removal of the stenosis of the vomer on the left side by drilling, but he would not consent. I had not urged it because, while the inferior meatus of the left side was practically closed, the middle and superior meati were large, and admitted a free current of air which had served the purpose of olfaction all his life.

All remedies having failed, general and local, I again suggested the propriety of removing the stenosis by operation; to this he acceded, and I performed the operation with Wagner's burrs attached to a dental engine, in the presence of several members of the profession. I first injected twenty minims of a four per cent. solution of the muriate of cocaine under the mucous membrane covering the stenosis, and also applied it freely over the outer side.

The operation was comparatively painless, with little hemorrhage; the inferior meatus was bored out in a few minutes to its normal size admitting the largest sized Wagner's nasal probe.

April 22.—The after-treatment consisted in cleansing the parts daily.

Twenty-two days have passed since the operation; the sense of smell has steadily improved on both sides in acuteness and persistency, and has been present nearly all the time for the past ten days. The patient is sanguine about the ultimate restoration of this important function.

Remarks.—I have described the above case of anosmia somewhat at length and the treatment adopted, because I think it presents some marked peculiarities differing from any case of the kind which has come under my observation, and from the usual class of such cases described in general or special treatises upon the subject.

With regard to the etiology of this affection, the causes are either centric or eccentric. Under the first there may be congenital deficiency of the olfactory nerve, or the centre of olfactory conduction or excitability may be inert or defective. Hemiplegia is often the direct cause of anosmia, and it is sometimes dependent upon hysteria difficult of explanation, and often present among the insane. To these may be added the various conditions of impaired function of smell arising from traumatic causes involving fracture of the ethmoid bone and injury to the olfactory bulb, some temporary, some permanent, owing to the extent of the injury inflicted at the time, and the powers of nature to repair the injury.

As an instance of traumatic anosmia, I attended a gentleman in January, 1878, who was shot by a pistol-ball on the border of the left superciliary ridge. For two days he had symptoms of concussion with nausea, after which he recovered. I suspected fracture of the orbital plate of the frontal bone, extending backwards to the sphenoid or ethmoid bones. Subsequent symptoms pointed to the ethmoid and olfactory bulb. He had anosmia and impaired taste until the following October (ten months). Since then he has continued well.

Among the eccentric causes we have an equally long list producing temporary or permanent loss of smell, nasal catarrh in the second and third stages, syphilitic ozæna, or the constitutional effects of syphilis not manifested by disease of the nasal mucous membrane, apparently affecting directly the olfactory bulb and nerves, the latter improving under an antisyphilitic course of treatment.

Tumors of the nose in their various forms, bony stenosis of the septum interfering with admission of air into the middle and upper meatuses, foreign bodies producing chronic thickening of the mucous membrane, with sanious discharges and necrosis of the turbinated bones.

As an instance of anosmia from foreign body in the nose, with necrosis of the inferior turbinated bone, I published a case of this kind in the *Transactions* of the South Carolina Medical Association for 1881, under the title of "Chronic Ozæna of Sixteen Years' Standing; a Quartz Pebble Impacted in the Inferior Turbinated Bone; Removal of Turbinated Bone; Recovery."

Wagner (*Diseases of the Nose*) mentions strong injections in the treatment of chronic rhinitis, and the long-continued use of the nasal douche, as causes of anosmia. He also relates a case, reported by Notta, of a person whose sense of smell was *totally* destroyed by superintending the cleansing of a sewer from the bad odor, and another occurring in his own practice of a flour inspector, who had lost the sense of smell for flour, while his sense of smell was *perfect for other odors*.

The last two cases are similar to the one reported above, the loss of smell being caused by the effect of odors upon the terminal branches of the olfactory nerve. In Notta's case smell was *totally* destroyed by the noxious odor of sewer gas suddenly inhaled. In Wagner's the loss of smell was confined to a *particular* odor. In the case I have described the party dated his loss of smell to sampling a particular cargo of meat after having returned from a pleasure tour of a month. His loss of smell, therefore, could not have been caused by the constant exposure to the bad odor of rancid or spoiled meat as a tester. His case seems to have been one in which the olfactory nerve was overpowered by the odor from a box of spoiled Bologna sausages in the cargo examined, and the deleterious effects upon the peripheral nerves of smell was gradually increased by his occupation.

It would have been amusing, had the consequences not been so serious, to notice the horror with which he spoke of that particular box of "bad Bologna sausages; it beat anything in all my experience, and had to be boxed up as soon as it was opened, and was a complete loss to the house." Another peculiarity of this case which I have not seen mentioned in the books, consisted in the *variability* of the function of smell lasting a few minutes or hours, then disappearing, to return again during the day, or sometimes wanting almost entirely for one or two days, this not being confined to a "professional bacon odor," but to odors of all kinds.

The influence exerted by the bony stenosis existing

Digitized by Google

in this case, and causing loss of smell, is questionable, although his improvement was very noticeable after the operation.

The patient had been subjected to local and constitutional treatment for eight months without practical improvement until the operation; but it should be stated that, though not actively engaged, from disability, as a tester of meat, he was all the time in the same building, and exposed more or less to the same odors in a modified form originally causing the difficulty.

Bony stenosis of the nose produces anosmia directly from mechanical occlusion, and is often associated with congenital anosmia, or indirectly by setting up after exposure a chronic rhinitis, and the loss of smell may be gradual. The latter is at first confined to the affected side, but very often extends to the other nostril, and smell on both sides may become obliterated. I have operated four times for the removal of congenital bony stenosis of the septum by drilling, and have now under treatment an elderly gentleman for chronic rhinitis impairing smell, dependent upon the same cause.

I think cases of this kind are more numerous than is generally supposed.

The occlusion may exist at any part of the middle or inferior meatus, but is most common near the anterior nares. I reported my first case to this Association in 1882, and it was published in the *Transactions* for that year; the three others have occurred since. All of them were on the left side, and had chronic rhinitis, with more or less anosmia, and were relieved by the operation.

NOTE.—June 5th: I saw the patient to-day; he reports continued improvement, and considers himself nearly well.

MEDICAL PROGRESS.

THE ADVANTAGES OF PERINEAL INCISION IN THE TREATMENT OF PROSTATIC AND PERIPROSTATIC SUPPURATION.—M. PAUL SEGOND, at a recent meeting of the Société de Chirurgie de Paris, read a paper upon the advantages of perineal incision in prostatic and periprostatic diseases, of which the following are the conclusions:

1. Rectal incision in prostatic abscess is an operation open to the following objections: It must be done without antiseptic precaution; it is insufficient; is dangerous at once on account of the hemorrhage which may result, and dangerous as to its results by its liability to produce urethrorectal fistula, which is frequently incurable.

2. The transverse perineal and prerectal incision presents none of these disadvantages. Strict antisepsis may be practised. The operation insures the complete drainage of pus, obviates the danger of hemorrhage, and when the abscess communicates with the urethra—at once, or later in the history of the disease, the gravity of the prognosis is diminished by the avoidance of a urethrorectal, and the creation of a urethroperineal fistula.

3. Extensive incision by the perineum is, therefore, to be preferred when practised according to the preceding rules, in all prostatic or periprostatic suppurations which have a tendency to open elsewhere than in the urethra, and should be resorted to when the perineum is yielding, and the lesions are exactly located above the middle aponeurosis.

The operation is also indicated as a valuable resource in the treatment of serious and intractable cases, characterized by the presence of fistula or of true prostatic cavities communicating with the urethra by an opening insufficient to permit the free drainage of pus, and the cicatrization of the purulent passages.—*L'Union Médicale*, June 16, 1885.

CASE OF VAGINAL ATRESIA WITH PURULENT RETENTION WITH PYOMETRITIS.—DR. J. ROSNER, in *Przeglod lekarski*, 1885, No, 13, reports the case of a girl, aged 18 years, who in November, 1884, came to the gynecological clinic of Prof. Madurowicz for treatment. Previous to this time she had for the most part enjoyed good health, but had never menstruated. Two years previously she began to suffer from abdominal pain, which came on at intervals, and usually continued some days, without vomiting or nausea. For some months preceding her appearance at the clinic, she had suffered continual pain in the abdomen, loins, and lower extremities, and during the last few days had had frequent chills followed by light fever. Examination after emptying the bladder, which extended to the umbilicus, showed the abdomen distended by a tumor of considerable size, which extended the breadth of three or four fingers over the symphysis pubis. The tumor was roundish in shape, the edges smooth, it was wholly immovable, and had a resistance corresponding to the uterus. The external genitals and perineum were swollen, and the labia majora were separated from each other about a half inch. The entrance to the vagina was closed by an imperforate hymen, which was much distended and pushed forward.

The urethra was firmly pushed upward against the pubic arch, so that the introduction of a catheter was very difficult. Fluctuation was plain. After a careful incision made layer by layer, with antiseptic precaution, through the hymen, which was about one-eighth of an inch thick, pus mingled with blood escaped without pressure to the amount of more than a quart, and this result was followed by the immediate relief of the patient. The vagina was irrigated with solution of carbolic acid, and an examination made showed it to be smooth, distended, its walls thickened. The external orifice was the size of a dollar, its edges forming a thick roll. The uterine mucous membrane was puffed and swollen, and the cervical canal contracted.

Rest in bed and irrigation of the vagina with carbolic solution was ordered. In two days the discharges ceased, and the patient left the hospital.—*Centralbl. für Gynäkologie*, June 13, 1885.

THE CLIMATIC TREATMENT OF PULMONARY TUBERCULOSIS.—DR. K. CHODOUNSKY makes the following *résumé* of the points worthy of consideration in the climatic treatment of pulmonary tuberculosis:

1. Contraindication to all climatic therapy is found (*a*) in the existence of high fever; (*b*) in great extension of the tubercular disease, unless its progress has ceased; (*c*) in a debilitated condition which compels the

Digitized by Google

patient to remain in bed; (*d*) peritoneal and intestinal complications.

2. Contraindications to an elevated region: (*a*) erethesis; (*b*) advanced anæmia; (*c*) changes due to advanced life, especially of the vascular system; (*d*) an habitually accelerated pulse; (*e*) diminished inspiratory power; (*f*) all fevers; (*g*) pneumonic tuberculosis in all stages; (*h*) chronic miliary tuberculosis with frequent exacerbations; (*i*) laryngeal catarrh and tuberculosis; (*j*) the stage of decay, unless under specially favorably circumstances; (*k*) complications with cardiac and vascular disease; (*l*) disease of the kidneys; (*m*) neuralgia and neuroses of typical nature.

Elevated climate is indicated for hemorrhagic cases as follows: (*a*) in hæmoptysis in the initial stage; (*b*) in light passive hæmoptysis; (*c*) in congestive hæmoptysis after discontinuance of the fever and an interval of eight weeks since the last hemorrhage; (*d*) in hemorrhagic cases with cavities, if the decay and the fever have ceased and no hemorrhage has occurred for a period of eight weeks.

3. Indications for an equable climate are: (*a*) moderate fever in which the temperature does not rise above 100.4° F.; (*b*) tuberculosis in the stage of decay with moderate characteristic symptoms; (*c*) hemorrhagic cases with cavities and moderate symptoms, and an eight weeks' interval since the last hemorrhage; (*d*) congestive hæmoptysis; (*e*) laryngeal catarrh and tuberculosis; (*f*) heart, vascular, and nervous complications for which the elevated regions are contraindicated; (*g*) cases in which irritability of the air-passages exists; (*h*) cases with diminished power of inspiration and an habitually accelerated pulse; (*i*) advanced anæmia; (*j*) advanced age.—*Allgemeine Wiener med. Zeitung*, May 19, 1885.

A CASE OF ALTERNATE PARALYSIS OF PEDUNCULAR ORIGIN.—DR. RAMEY reports a case of alternate paralysis which, during life, exhibited the following characteristics: Incomplete hemiplegia of the right side, and paralysis of the left common motor-oculi. Post-mortem examination revealed the presence of a caseous tubercle the size of an almond, situated in the cerebral peduncle and the left optic thalamus.

Points worthy of note in the history of the case are:

1. Notwithstanding the complete destruction of the optic thalamus, the patient presented no signs of sensory disease, except what were slight and transitory.

This condition is in opposition to those authors who consider the optic thalamus as the centre of sensitive and sensorial perception (Luys, Fournié).

2. The results of the experiments of MM. Brown-Séquard, Budge, and Afasanieff, show that section of the cerebral peduncles determines in animals serious vaso-motor disturbance. In the patient now under discussion there was, from the origin of the affection, a permanent sensation of cold in the right arm, whose temperature was in reality lower than that of the same member of the opposite side, although there was no appreciable difference in the color of the hands or forearms. Only during the last ten days of life did the right hand exhibit any peculiarity, and at this time it became œdematous and of a reddish carmine hue.

3. The researches of Afasanieff and Budge, upon the function of the peduncles, seem to have established a relation between this region and the sphincters of the rectum and bladder. In the case under consideration there was no evident disturbance of the function of these muscles—except at the period immediately preceding death—a time when the general depression of all the vital forces was sufficient to explain the condition.

4. In spite of a relatively gross lesion located in the optic thalamus, and which destroyed a large portion of the superior floor of the peduncle, the spinal marrow presented no trace of secondary degeneration—a condition which seems to prove that the optic thalamus and the superior peduncular floor do not form an integral portion of the cerebral motor apparatus; or, at least, do not have a trophic influence upon the pyramidal fibres.—*Revue de Médecine*, June, 1885.

EXPERIMENTAL INOCULATION OF TUBERCULOSIS AND GLANDERS.—DR. CHARRIN, in an experimental study of tuberculosis and glanders, has determined that inoculation does not prevent glanders; and that, most probably, auto-inoculation in this disease is produced more readily than in the case of tuberculosis. He further holds that, just as in the acute infectious diseases, there are some which ordinarily do not recur—typhoid fever, etc., and others which may be repeated; so, in the chronic infectious diseases, or in those ordinarily chronic, there are some which, like syphilis, cause an immunity to recontagion; and others, as glanders and tuberculosis, which, at least constantly, do not obey this law.—*Revue de Médecine*, June, 1885.

METHOD OF OPERATING IN LAPAROTOMY FOR INTESTINAL OBSTRUCTION.—MR. J. GREIG SMITH gives the following concise rules for the operation of laparotomy in intestinal obstruction:

1. Make the incision in the middle line below the umbilicus.

2. Fix upon the most dilated or the most congested part of the bowel that lies near the surface, and follow it with the fingers, as a guide to the seat of obstruction.

3. If this fail, insert the hand, and carry it successively to the cæcum, the umbilicus, and the promontory of the sacrum.

4. If this again fail, draw the intestine out of the wound, carefully covering it, until increase of distention or congestion, or both in one of the coils, gives an indication that the stricture lies near.

5. If there be considerable distention of the intestines, evacuate their contents by incision, and suture the wound. Never consider an operation for intestine obstruction inside the abdomen finished until the bowels are relieved from overdistention.

6. Be expeditious, for such cases suffer seriously from shock. The whole operation ought to be concluded in half an hour.—*British Medical Journal*, June 13, 1885.

INTRAVENOUS INJECTION OF MILK.—MR. CHARLES E. JENNINGS, after reviewing the current literature on the clinical intravenous injection of milk, and also the results of physiological experiments with such injections, concludes:

1. The intravenous injection of a small quantity of newly drawn milk is harmless.

2. Large injections of milk are fatal, with polyuria as the chief symptom.

Digitized by Google

3. The employment of impure, or stale milk, is most dangerous, on the probability that septicæmia will follow the operation.

4. The operation is to be recommended in the later stages of cholera, enteric fever, phthisis, and pernicious anæmia, as a substitute for the transfusion of blood; and, in short, in all cases where transfusion of blood is indicated on nutritive grounds, but where a blood-donor cannot be procured, or where this operation is, for other reasons, impracticable.—*British Medical Journal*, June 6, 1885.

THE SUBCUTANEOUS DIVISION OF THE SPHINCTER ANI.—MR. T. PICKERING PICK, after reporting a case in which spasm of the sphincter ani was successfully treated by subcutaneous incision, says: In thinking over this case, it occurred to me that we had in this simple operation a decided improvement on the one usually performed for that very distressing complaint, fissure of the anus. The usual operation consists in passing a blunt-pointed knife into the anus and cutting outwards through the base of the ulcer, so as to divide the fibres of the sphincter muscle, and this produces a very considerable wound, which always takes from ten days to a fortnight to heal, and sometimes a very much longer period, during which the passage of the motions over the sore causes the patient a certain amount of pain and annoyance, and exposes him to the risk of septic absorption.

The object of this operation is to paralyze the action of the muscle, which by its movement prevents the ulcer from healing. And it will be often found by those who are frequently called upon to perform it, that if the muscle is imperfectly or insufficiently divided, entire quiet is not obtained, and the undivided fibres, though paralyzed for a time, soon recover themselves, and the old trouble reappears. It seemed to me therefore that by subcutaneous division of the muscle we attained three ends: (1) a complete division of the whole muscle, and therefore a more certain result; (2) a small puncture instead of a large wound, and therefore more rapid healing; (3) a subcutaneous wound and less chance of septic absorption.

There is also another class of cases in which I think the operation of subcutaneous division of the sphincter ani may advantageously be resorted to, and that is in the operation for internal piles, whether that operation consists in ligaturing, searing, or crushing them. It has been for some time in my practice, and I have no doubt it is the practice of every one who operates in these cases, to commence proceedings by forcibly stretching and paralyzing the sphincter. There can be no doubt of the great advantages to be derived from this proceeding, for not only does it fully expose the lower part of the rectum, so that it can be thoroughly explored, but it also does away, to a great extent, with the spasmodic pain, which is otherwise such a frequent sequel to this operation. Stretching is performed by introducing the two thumbs into the rectum and thoroughly extending and, no doubt, rupturing some of the fibres of the sphincter ani by separating them in the antero-posterior and lateral directions, using an amount of force sufficient thoroughly to overcome the spasm. For this somewhat unsurgical proceeding I now substitute subcutaneous division, an operation which thoroughly exposes the lower three inches of the rectum, without such laceration and bruising of tissues as forcible stretching must produce, and entirely does away with the pain from spasmodic contraction which, in spite of the stretching, often, in my hands at least, followed the operation.—*Medical Times*, June, 6, 1885.

TREATMENT OF STONE IN THE BLADDER.—MR. REGINALD HARRISON, at the conclusion of an elaborate paper upon the treatment of stone in the bladder, says, in reference to the management of hemorrhage:

The treatment of immediate and secondary hemorrhage in cases of lithotomy, prostatotomy, and cystotomy, has given me much consideration, as in a large experience of these operations instances of these complications have from time to time arisen. When an artery has been divided, and is evidently spouting, it must be tied; this can generally be done with the aid of retractors without much difficulty; to plug a spouting vessel, if it is possible to avoid it, is to court the recurrence of a bleeding. More usually I have noticed, as in section of the prostate and adjacent parts, this bleeding is of a freely oozing nature, as if from spongy textures, but in this way many ounces of blood may be quickly lost. I have invariably noticed in the cases referred to, when the bleeding has been of this oozing nature, how easy it is to control it with the point of the finger introduced and well carried into the bottom of the wound, sometimes even by the finger in the rectum. For the finger in the wound I now (since the fatal case just recorded) substitute a lithotomy tube of a size which precisely fits the wound-cut in the bladder that has been made. I have them made of different calibres, so that they may fit with tolerable accuracy. They are tied into the bladder by the usual perineal band, and drainage through them is carried on by the inner rubber tube, which can be changed at will, and by which the bladder is washed out and the urine carried into a vessel by the patient's bedside.—*Annals of Surgery*, June, 1885.

DIFFERENT VARIETIES OF ORCHITIS CONSECUTIVE TO URETHRAL CATHETERIZATION.—DR. BARETTE, in discussing the different forms of orchitis due to urethral catheterization, reaches the following conclusions:

1. Patients suffering from prostatic disease, or from stricture, are subject to certain testicular complications due to catheterization, the more as their urethral mucous membrane is altered and vascular.

2. The orchi-epididymites which supervene are developed under two different forms: the simple acute and non-suppurative, and the acute suppurative variety.

3. In every case the point of departure is a lesion of the mucous membrane at or in the region of the ejaculatory orifices.

4. The inflammation starting from this point appears to advance along the lymphatic channels of the seminal apparatus, and thus reaches the testicle and the tunica vaginalis testis.

5. The morbid, or healthy condition of the urine, and old or more or less extended alterations of the urinary passages, seem to play an important part in the clinical form of the orchitis, and to determine whether it is simple or suppurative.—*Journal de Médecine de Paris*, June 14, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JULY 18, 1885.

THE OUTLOOK FOR THE CONGRESS.

To those who know anything of the characteristics of the international assemblies of the medical profession, known as Medical Congresses; or of the views of the leading medical men of Europe, whose concurrence is essential to make such meetings interesting or valuable, it must now be evident that the action of the American Medical Association, and of its new Committee, if persisted in, will result in a disgraceful failure.

It is possible that the Association may succeed in gathering one or two thousand men to attend such a meeting in Washington as its Committee proposes; and we will admit that it is possible, though very improbable, that it may succeed in raising sufficient funds to provide for the material part of the performance, but it most assuredly will not be able to induce the presence of a fair representation of the leaders of medical thought and progress from this or any other country.

Nor will the consequences be limited to the fact that the proposed Congress will rank far below those which have preceded it in the importance and interest of the papers presented, and the discussions to which they give rise. Were this all that is to be feared, the matter would be one rather for contempt than for apprehension. Those who decline to sanction the new programme, by refusing to allow their names to appear in connection with it, will lose nothing in reputation among our foreign friends, who will understand and appreciate their motives, and will, at the same time, free themselves from a very considerable amount of labor and responsibility. The danger is to the American Medical Association itself, and to the unity of the profession in this country.

The men who are engaged in original research, and who are best known as those who are contributing to the honor and dignity of American Medicine by their writings and teachings, are not usually active in medical politics or in the supervision of their medical brethren, nor are they given to logrolling and striving for office. For the past ten years these men have been becoming dissatisfied with the tone of the American Medical Association, and while many of them have not formally severed their connection with it, they have nevertheless ceased to attend its meetings. Many of them give their entire interest and work to purely scientific associations such as the College of Physicians and the Academy of Medicine, to pathological societies, or to societies devoted to specialties, in which the scientific physician is not liable to be annoyed and overborne by wire-pulling and loud-voiced demagogues.

The result of this interference with the Congress, and of the evident determination of the leading spirits in this movement to maintain their control over the Association, will be to alienate still further the scientific workers and teachers of the profession, and already we hear rumors of the formation of a new National Society, to meet the wants and wishes of this class. This result will fatally damage the influence of the Association, and it is greatly to be regretted, for the Association has done good, and might do much more if it were conducted in the interests of the whole profession.

The leaders of the new Committee are at present actively engaged in trying to devise some form of compromise which will enable them to retain their own positions, and at the same time prevent further defection, but this cannot be done. The leading members of the profession of the principal cities of the Union have declared their determination not to accept office. The presidents of nine of the Sections, the Secretary-General, as well as a large proportion of the vice-presidents and members of the Councils, have likewise declined to coöperate under the new organization. Self-respect, if nothing else, demands that a committee which has been so thoroughly discredited by the profession at large, and whose inability to organize an International Congress has been completely demonstrated, should at once resign. If its members do not, they fully justify the charge which has been freely made, that they place their individual interests above those of the profession, and that they prefer to see the Congress destroyed than themselves without office.

BRONCHIAL ASTHMA.

THERE are few affections upon which so much has been written, and in which permanently successful treatment has been so unsatisfactory as bronchial asthma. But it is only by continued, well-directed study of the subject that we can hope to secure that accuracy of knowledge upon which alone must depend a rational and successful treatment.

Considerable attention has recently been given to asthma in some one or more of its modes of manifestations, and apparent advances in pathology and treatment have been attained, both in this country and in Germany. Thus, DR. CURSCHMANN, of Hamburg, recently read a paper on bronchial asthma, before the Congress für Innere Medicin, at Wiesbaden, confining himself to those cases characterized by a sudden or rapidly increasing and equally rapidly declining dyspnœa, having its seat in the smaller air passages, is predominatingly expiratory, and is associated with emphysema and, for the most part, with prolonged expiration.

The cases included in this category he further subdivides into two groups, which he calls primary and secondary, and of which the most important is the secondary. In this class he includes those cases in which the cause of the asthma lies either in a part remote from or adjacent to the respiratory apparatus itself, whence the asthmatic attack is induced for the most part in a reflex manner. These reflex cases he again divides into two groups, of which one has to do with unaltered respiratory passages, while the other s associated with abnormal conditions.

In the latter group he especially includes what is now generally described as bronchialitis exudativa, characterized by the presence of spiral coagulated products in the sputum, although Curschmann does not claim, as some others do, that the presence of these spirals necessarily implies asthma. According to him, there must also be the affection of the mucous membrane with the intense irritability consequent upon it. The simple clothing of the bronchial mucous membrane with such a secretion would explain a bronchialitic dyspnœa, but not a bronchialitic asthma. He leaves open the question whether spasm of the diaphragm has anything to do with the attacks of asthma. He does, however, insist that the bronchialitic condition is primary, and the asthmatic, secondary.

As to the first group of secondary asthmas, where the bronchial passages are intact, Curschmann regards as especially important those asthmatic attacks which emanate from disease of the nose and nasal spaces. They include swellings and hypertrophies of the turbinated bone, polypi, exostoses, etc. They produce the so-called nasal asthma. Especially serious cases are those instances of nasal asthma which are accompanied by exudative bronchialitis.

Of that form of primary asthma in which the cause resides in the brain, or the nervous paths which lead from the brain to the respiratory apparatus, Curschmann has had no cases, and believes it to be at least very rare.

The prognosis varies with the patient and cause of the disease, being most favorable in those cases where the condition is due to reflex processes, while the lung itself is unaffected organically. Much more serious are the cases due to exudative chronic bronchiolitis.

In the treatment narcotics hold the first place, and probably cocaine is destined to play an important role. In the treatment of the general condition iodide of potassium is very valuable. Surgical measures may be useful. Many cases of nasal asthma recover entirely, while others only partially recover, or relapses take place.

In this connection we may call attention to the new work of DR. SAJOUS on "Hay Fever and its Successful Treatment." According to his views, hay fever would exemplify that form of asthma which Curschmann has never met,—the form in which the cause resides in the brain and nervous paths which lead from the brain to the respiratory apparatus. For, according to Dr. Sajous, persons subject to hay asthma possess, as the result of heredity, diseases implicating markedly the nervous system, nerve centres which have become abnormally sensitive and are therefore inordinately influenced by the external irritants to which they respond. But this is not the whole of the pathology of hay asthma, according to Dr. Sajous. Not only must there be a hyper-excitability of the nerve centres, but the nasal mucous membrane must be hyperæsthetic, and capable of transmitting to the abnormally sensitive nerve centres the impression made upon them by external irritants, which are supposed to be the pollen of flowers and certain other unknown elements which prevail only from June to September. Given the absence of any one of these conditions and the patient is spared the attack. The absence of the physical element, whatever it may be, which causes the irritation may be secured by removal to certain localities where it does not prevail.

Dr. Sajous secures the removal of the irritable mucous membrane by eliminating, first, the abnormal conditions of the mucous membrane, that is the swellings, hyperostoses, etc., by suitable treatment; and second, by cauterizing the hyperæsthetic nasal mucous membrane, and thus rendering it insusceptible to the irritating agencies. This is the new and successful treatment of hay asthma, in the early use of which Drs. W. H. Daly, of Pittsburg, J. A. Roe, of Rochester, and Prof. Harrison Allen, of Philadelphia, have, also, been conspicuous. We sincerely hope

Digitized by Google

that further experience may confirm these preliminary statements, and that "hay" or "rose" asthma may no longer be the opprobrium it has always been to the science of medicine.

THE RESPONSIBILITY OF GREATNESS.

THERE are some persons who may say whatever they choose without running much risk of doing harm if they happen to be wrong, while there are others whose lightest utterances are of the gravest moment, and who run a correspondingly great risk of doing damage, if what they say happens to be without good reason. To this number belong those distinguished men in our profession who, by their learning and experience, have come to occupy positions from which every expression of opinion carries almost conclusive weight to those who hear them. The honor of this position is no greater than its responsibility; and though the latter occasionally seems to be lost sight of, it may be that distinguished men think too modestly of themselves to understand how highly they are appreciated by others, and that this may lead them to overlook the preponderating weight of what they say, as against the sayings of those whom the world rates far below them. However this may be, it is, unfortunately, no rare thing for one who has an extensive and well-deserved reputation for learning in the science and art of medicine to express an opinion in regard to some detail of this science or art about which he has less precise knowledge than it might be supposed he has, in regard to which, in fact, he is mistaken, and about which he becomes the father of error. The worst of the matter is that the very merits of one who may do this deepen and widen the mischief.

This is a state of affairs which is probably inseparable from the constitution of men's minds, and an essential part of that proper respect for years and position which lies at the foundation of all stability in scientific matters. But the recognition of this liability to err should form a part of the preparation of every man of consequence for the expression of his opinions, especially on controverted points. Failure to recognize it may lead to mistakes which mislead others, and leave an unfortunate record for the inspection of posterity.

An illustration of this is to be seen, from time to time, in items which go the rounds of the medical journals, and which are sometimes found in those which take special pains to be select in their citations. Thus the *London Medical Record* recently contained an abstract of the opinions of Prof. Sperino on the "analogy between syphilis and rabies," on studying which we have been forced to the conclusion that it would be hard to put in so small a space the evidence of greater ignorance of the subject discussed. It is evident, from what is cited, that Prof. Sperino, notwithstanding his eminence, is entirely unfamiliar with what is knowable—we dare not say what is known—about the subject of rabies or hydrophobia. When Prof. Sperino says that "hardness of the lymphatic glands before the development of the disease, and a prolonged incubation, are common to" both hydrophobia and syphilis, he shows that he has made the common mistake of confusing what is striking, but exceptional, with what is ordinary, but less likely to be the subject of remark. When he says that "hardness round the wound in hydrophobia corresponds to the hard sore in syphilis," he is manifestly unaware of the fact that a careful study of a large number of cases of so-called hydrophobia shows indubitably that induration at the seat of the suspected bite is very rarely to be noted, and deserves no more consideration than the temporary hardness of most cicatrices. When he speaks of "Marochetti's vesicles" as corresponding to the mucous patches of syphilis, he certainly cannot be informed that the existence of the so-called "Marochetti's vesicles" is as purely a matter of imagination and misapprehension as is the existence of the moon-stone.

This slip of Prof. Sperino is a new illustration of the time it takes for the truth to catch up with falsehood. Allusions to the vesicles of Marochetti appear with tolerable regularity in articles on hydrophobia, which come from men who have not heard that the inventor of these vesicles was probably a charlatan, and that, after rigid scrutiny, both he and they have been relegated to the limbo of medical literature.

Again, Prof. Sperino says that hydrophobia, like syphilis, is transmitted by heredity—a statement which robs us of any right to be surprised at any other which he may make on this subject; while his assertion, that hydrophobia is not communicated by the milk, although perfectly true, is in direct opposition to a much greater mass of the same sort of evidence as is available to establish the hereditary transmission, which he does not hesitate to accept.

The culmination of Prof. Sperino's errors is reached when he speaks of the treatment of hydrophobia. Here he actually cites eleven cases of "mad-dog bites" in which there was hardness of the lymphatic glands, and in which mercurial frictions removed this condition. One child, he says, had several bites, and, owing to some of the wounds having been neglected, the first symptoms of hydrophobia appeared, but yielded to mercurial frictions. The author concludes, however, that "these eleven cases do not warrant a proclamation of the prophylaxis of rabies."

In all this there is shown the same ignorance of what has been tried and found wanting long ago which marks most of the utterances in this communication. In fact, the whole theory of the analogy of syphilis and hydrophobia is an ancient thing. John Douglas

Digitized by Google

put it quite succinctly more than a hundred years ago when, speaking of hydrophobia, he said "that antidote which most effectually expels the malignant and deadly poison conveyed by the sting in a harlot's tail, must also be the best antidote against the sting of the scorpion, the bite of the viper, rattlesnake, and all the serpents in the East or West Indies." And it is more than three hundred and fifty years since Palmarius first suggested the use of mercurial frictions in the treatment of hydrophobia—a suggestion which, after centuries of testing, has proved utterly useless.

Unfortunately, the profound ignorance of most medical men in regard to the literature of hydrophobia prevents the immediate rejection of such already thoroughly discussed and thoroughly exploded suppositions as these. Unfortunately, too, this very ignorance is likely to lead to the adoption of Prof. Sperino's ill-founded opinions on his sole authority, and to favor the propagation of the darkness which they were intended to enlighten.

Thus we see that eminence is no guarantee of infallibility, and once more is illustrated the possible perversion of the influence of authority, which, when rightly used, is one of the best as well as one of the most important agents in the formation of a correct scientific opinion. Let those, then, who, however modest, must be aware that a special value is attributed to whatever they say, exercise the greatest caution in expressing views which they have formed from inadequate investigations, and let them do this all the more if their opinions concern matters which have been the subject of careful research on the part of others.

ALBUMINURIA AND THE MERCURIAL TREATMENT OF SYPHILIS.

AT the recent Congress of German Physicians FÜRBRINGER, of Jena, read a paper upon the albuminuria of syphilis with and without mercurial treatment. He found that of secondary syphilitics who before treatment were not albuminuric, eight per cent. became albuminuric during treatment. In cases of primary syphilis not treated with mercury, albuminuria occurred in twelve per cent. of cases, almost always in the stage of disappearance of roseola; with the exception of three cases, the albuminuria disappeared with the institution of mercurial treatment.

In the discussion which followed, SCHUSTER claimed that cases of serious albuminuria due to syphilitic renal disease recover by mercurial treatment, and that there is no contraindication to the use of mercury in these cases.

SCHUMACHER had observed several cases of simultaneous syphilis and nephritis, and was satisfied that the nephritis preceded the syphilis and continued during the further development of syphilitic phenomena. The mercurial treatment used in these cases did not aggravate the symptoms of nephritis.

In his quite recent work on *Urinary and Renal Disorders*, DR. BEALE says, "of all the forms of chronic renal disease, those which are due to syphilis are the most likely to get well." Even in large albuminurias, with considerable and persistent dropsy, improvement may be confidently predicted, and even recovery not uncommonly takes place in the course of a few months.

The treatment in the early stages is that usual for Bright's disease—purgatives, warm baths, and hot air baths. When the albumen is reduced to one-fifth and urine is passed freely, he recommends iodide of potassium, iodide of iron, and other preparations containing iodine. Complete recovery is often thus produced after judicious treatment is kept up steadily for two or three months.

Dr. Beale thinks that the glandular enlargements, of which the kidney is an example, in syphilis, were less common when the mercurial treatment was more in vogue, although he admits that necrosis is less frequent. There can be no doubt that the judicious combination of the alterative with tonic chalybeate treatment in syphilis as contrasted with expectant treatment is calculated to be most serviceable.

SOCIETY PROCEEDINGS.

KENTUCKY STATE MEDICAL ASSOCIATION.

Thirtieth Annual Session, held at Crab Orchard Springs, June 24, 25, and 26, 1885.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, JUNE 24TH.—FIRST DAY.

AFTERNOON SESSION.

ONE of the most interesting and at the same time one of the largest meetings of the Kentucky State Medical Association assembled, at 4 P.M., in the hall of the Springs Hotel, of that historic little town Crab Orchard, near the southern border of the State.

After the call to order, by THE PRESIDENT, PINCKNEY THOMPSON, M.D., of Henderson, and prayer, the members received a cordial welcome from the President of the Crab Orchard Springs and Salts Company.

The address of welcome on behalf of the Committee of Arrangements together with their report, was made by DR. EDWARD ALCORN, of Hustonville.

DR. WILLIAM BAILEY, of Louisville, then read his report, as Chairman of the Standing Committee, on

THE PRACTICE OF MEDICINE.

In review of the important features of the practice of medicine at the present time, he passed a scathing criticism upon the method employed by so many of our leading drug manufacturers for the introduction of their wares to the profession. The sending of samples has reached such proportions as to be of necessity a nuisance to the practitioner. The time has come for the pro-

Digitized by Google

fession to call a halt upon this custom and to demand that the practitioner shall prescribe the manner in which his remedies shall be prepared and not submit to whatever the fancies of the manufacturer may direct. As a rule these preparations come well attested, so far as the number of certificates is concerned, but all know how and whence such testimonials are obtained and of how little value they are as evidence of the quality of the article to which they refer.

Few subjects at the present season claim the interest that cholera is assuming, owing to its appearance again in Spain. High honor is due, he said, to those fearless investigators who are devoting their time and energies to the discovery of the cause and mode of prevention. The hope was expressed that they may be rewarded by the discovery of facts that shall lead to its prevention or even its cure. The relation between the comma-bacillus and cholera was next considered. Koch, as is well known, has discovered a bacillus for which he claims the origin of the disease. Straus has described a bacillus which he believes the same as that of Koch, but which was found in the alimentary canal of healthy individuals. In the light of recent experiments it is probable that the comma-bacillus is a result rather than a cause of cholera. Why is it, he asked, that the bacilli, if the cause of cholera, are not found in the blood and in all the tissues, just as we know the poison of smallpox must exist.

For the germ theory he expressed admiration, but thought that the whole subject should still be held *sub judice*. In the end we shall probably find that the cause of cholera as well as of dysentery, malaria, and other infectious diseases, is atmospheric and telluric rather than the presence of microörganisms.

DR. DUDLEY S. REYNOLDS, of Louisville, failed to recognize the force of the logic employed: First, he could see no force in the objection to the finding of the bacillus only in the alimentary canal; and, second, he could see no analogy between cholera and smallpox. It is well known, that whatever the cause of the former disease, it produces its results by so irritating the lining of the intestinal tract as to deplete from the general circulation to such an extent as to cause fatal thickening of the blood. Smallpox, on the contrary, is a disease of the blood. The speaker favored the germ theory, and thought that the recent investigations of the epidemic at Plymouth, by Drs. Shakespeare and French, had added much force to the belief that typhoid fever also depends upon the action of a germ.

DR. JOSEPH N. MCCORMICK, of Bowling Green, thought the germ theory of the origin of cholera better established than the theory of atmospheric and telluric origin. As an argument for this we need but refer to the fact that the disease does not always prevail with anything like the same degree of severity in different places having, so far as we can discover, precisely the same atmospheric and telluric surroundings when infected at the same time. Special consideration was directed to the outbreaks of cholera in this country in 1873, and in France and Italy last year. In every instance where careful investigation was made of the origin of the disease in any particular district, it was found to be clearly traceable to a previously infected locality.

DR. YEAGER, of Campbellsburg, objected to the germ theory as not being sufficiently established and placed more importance upon the atmospheric and telluric influences in the production of an outbreak of cholera.

DR. J. B. MARVIN, of Louisville, feared that the essayist had not pursued his studies of the cholera bacillus quite to the extent to which he should have done before making a positive statement of his disbelief in the theory of its causative relation to the disease. There have been described, up to the present time, at least three distinct varieties of comma-bacilli, one described by Koch and two supposed by their discoverers to be the same as he had described. Of only one variety however could it be asserted that it was capable of producing cholera. Koch has not only produced the symptoms of the disease by inoculation with the germs he had discovered but he has cultivated them and produced the same results from inoculation with germs of succeeding generations of the microörganism. In conclusion and in argument for the truth of the germ theory of the disease, the author cited the outbreaks of the disease that have occurred at Mecca. It has been observed that notwithstanding the obligatory presence of large numbers of pilgrims, all obliged as a religious duty to drink of the water of a single well, cholera did not appear until the pilgrims arrived from certain districts where the disease was endemic. Upon one occasion when there were present 100,000 pilgrims, a band arrived from one of these infected districts; the disease broke out within 48 hours and in the space of but a few days had destroyed 15,000 people.

DR. BAILEY, in concluding the discussion of his paper, remarked that he had wittingly made few positive assertions. His object, upon the attainment of which he felt that he had reason to congatulate himself, had been rather to exhibit that wholesome amount of scepticism which is always an incentive to the investigation of a subject and a means of arriving at the truth.

EVENING SESSION.

VICE-PRESIDENT DR. L. S. MCMURTRY, of Danville, being in the chair, THE PRESIDENT, DR. PINCKNEY THOMPSON, of Henderson, delivered the

ANNUAL ADDRESS.

In introduction he congratulated the Association upon its having attained the honorable age of thirty years and upon the large number permitted to be present. Meetings of this sort are profitable in many ways. Here we compare views, and interchange opinions on the causes and treatment of diseases. It is a safe assertion that the physician occupies a position second to no other class of men. An old Roman said, "Men are never so like gods as when their aim is to secure health to their fellow men." The true physician must be upright, truthful, pure, with the sick and with the well.

The remaining portion of the address discussed the evils which are at present sapping the life of society, particularly the errors of education and dress, becoming more and more recognized as responsible for the destruction of the physique of the young, and especially of young women. The building of high, four and five story schools was particularly condemned, on account of the harm resulting from the necessary amount of climbing in going from one recitation-room to another. Bad ventilation of these buildings is another evil of the

Digitized by Google

greatest importance. In conclusion it was asked, Are we in our daily intercourse with people among whom we practise and who will heed our words, warning them of the great importance of observing all these hygienic laws, especially in the family and school-room. If not, then we have missed a most important part of our calling, and have fallen short of the high ideal of our noble profession.

DR. E. WILLIAMS, of Cincinnati, then read a paper entitled

A PHYSICIAN'S OPPORTUNITY OF BEING AND DOING GOOD.

It opened with severe, but seasonable, attacks upon quackery and the manufacturers of quack nostrums. The essayist then drifted into the discussion of a pseudo-theological system of medicine, in which the physician and minister should walk hand in hand, each aiding the other in his efforts to elevate the spiritual and bodily condition of those by whom he is consulted. The address was full of good practical suggestions for both the profession and the public, and was enlivened by numerous anecdotes and tales of experience.

THURSDAY, JUNE 25TH.—SECOND DAY.

MORNING SESSION.

THE BOARD OF CENSORS

announced that a communication had been received from the Boyle County Medical Society, complaining that two of the members of the State Association from that County were not members of the said County Medical Society, as required by the Constitution, The Board had carefully considered the matter, and had arrived at the conclusion that there was nothing in the communication requiring the action of the State Society, but that the matter properly belonged to the County Society, to which it was referred. It was further the opinion of the Board that the clause requiring membership in a county society as a qualification for becoming a member in the State Association, referred only to the time of becoming a member, and that membership in the latter Association could be continued without continuing a member of the County Society, provided the other requirements of regular standing in the profession were not violated.

THE REPORT OF THE SECRETARY,

DR. S. M. LETCHER, was next read. From a large correspondence with the members of the Association, the Secretary was pleased to report an unabating interest in medical matters, and a prevailing desire for the welfare of the Association.

COMMUNICATIONS.

A communication was read from the Secretary of the American Medical Association, asking the assistance of this Society in securing the passage of an act by the Legislatures of the several States providing for the appointment of State boards of medical examiners. A committee was appointed to consider the best method of complying with the request.

A communication was read from the Committee of the American Medical Association on the Collective Investigation of Disease, asking that a committee be appointed by this Society to coöperate with it.

A communication from the Association of Superintendents of Asylums for the Insane asked that the Society extend its assistance to secure some action that will prevent the immigration to this country of the so-called defective classes of society. A committee was appointed to report the best manner in which to comply with the request.

The Committee on Nominations made the following report of

OFFICERS FOR THE ENSUING YEAR:

President.—J. P. Thomas, M.D., of Pembroke.

Vice-Presidents.—I. A. Shirley, M.D., of Winchester, and R. C. McCord, M.D., of Lebanon.

Permanent Secretary.—J. Steele Bailey, M.D., of Stanford.

Assistant Secretary.—Fayette Dunlap, M.D., of Danville.

Treasurer.—Edward Alcorn, M.D., of Hustonville.

Librarian.—J. S. Taylor, M.D., of Warren County.

To fill vacancies in the *Board of Censors*, S. M. Willis, M.D., of Winchester; J. M. Harwood, M.D., of Shelbyville; E. M. Prenter, M.D., of Midway.

Committee of Arrangements.—S. M. Willis, M.D., Chairman.

Place of next meeting, Winchester; *time*, the last Wednesday of June, 1886.

The report of the Committee on

GENERAL SURGERY

was read by DR. J. M. MATHEWS, of Louisville.

Before entering upon the history of surgery for the past year, he spoke in pleasing eulogy upon the late Dr. S. D. Gross. The Nestor of American surgery has departed; the mind that has done so much to increase our knowledge has become still. It was a matter of pride to the Association that it had been esteemed as one of his own children by a man so eminent.

The author referred to the leading operations that have attracted attention during the past year. Disinfection, climate, hygiene, and the care of the patient after operation, were credited with as great importance as the operation itself. Since the last meeting of this Society there has been given to surgery a boon second only to chloroform. The field of application of cocaine is wide. A brief consideration of its physiological action followed. The author thought, from his own observation, that the drug prevented to a slight degree the prompt union of wounds made under its action.

A few remarks were directed to the comparative safety and value of the several anæsthetic agents. The reporter preferred chloroform, and thought it about as safe as ether or any of the combinations. Rectal etherization has not proved the boon that it was expected to be.

The several disinfectant agents and the methods of their application were discussed. Referring to the efficiency of disinfectants, he remarked that with our present knowledge of their action it is possible for the surgeon so thoroughly to disinfect himself as to operate fearlessly within a short time after attending a septic case. He also quoted the statement made by Volkmann, in a communication to Dr. George S. French, of Minneapolis, that a man may safely go from the dissecting-room to the obstetric bed. The recent advances of abdominal surgery were described.

Digitized by Google

DR. W. CHEATHAM, of Louisville, objected to the statement that cocaine deterred to any extent the union of wounds made under its action. He, however, had observed that, in addition to its other properties, it possessed positive styptic properties; but, notwithstanding this, he thought that it rendered the occurrence of secondary hemorrhage a little more likely.

DR. W. F. COOMES, of Louisville, remarked, with reference to abdominal wounds, that interference is generally too long deferred. If he should himself receive an injury of any sort about which there was any hesitancy on the part of the attending surgeon, he should say operate at once. Abdominal wounds will heal as promptly and as thoroughly as wounds of any other part, provided cleanliness is made a cardinal feature of the treatment. Of iodoform he reported that he has used it freely in diseases of the nose, throat, and eye, and considered it of especial value in painful affections. He had found it would relieve promptly the most excruciating pain in the larynx. He then reported the case of a physician who had used it by insufflation in the quantity of two grains every morning for seven weeks, without evil result. But one morning, in about fifteen minutes after its use, he began to suffer from toxic symptoms, dizziness, depressed action of the heart, etc., and this continued at each insufflation as long as he continued to use it.

DR. A. DIXON, of Henderson, then read a paper on

LAPAROTOMY.

He reported a case of abdominal tumor which proved to be a large uterine fibroid, producing ascites. The tumor continued to increase rapidly in size after the reporter first saw it, becoming so large in the course of five or six months as to fill the entire abdominal cavity, rendering surgical interference positively necessary. The operation was performed on the 23d of May, after the method of Schede. The various steps of the operation were described, with special reference to the ligaturing of the pedicle and its separation. The abdomen was carefully cleansed and the edges brought together and secured according to Volkmann's method. The patient rallied well from the operation and had no untoward symptoms until the tenth day after. Her temperature then arose suddenly to 104°. The dressing was removed, and a small quantity of pus flowed from several suture wounds. After removal of the sutures, carbolized water was forced through the openings, washing out a small quantity of pus and necrosed connective tissue, The dressing was reapplied, and this method of treatment was carried out daily during the further progress of the case, with the effect of preventing the return of any unpleasant symptoms. He thought that in this case, as in the majority of such cases, the suddenly arising fever is of an aseptic character, and not pyæmic, as is sometimes supposed.

DR. E. WILLIAMS, of Cincinnati, referring to the remark of a previous speaker, said that he had found the American preparations of cocaine unreliable, and that he now used only that of Merck, of Germany. He had not observed any increased liability to secondary hemorrhage after its use. A case was reported in which his assistant had removed a small dermoid cyst from just above the eye, attempting to prevent suffering by cocaine, but without very good result.

DR. A. M. VANCE stated that his experience with the drug in general surgery had been a little more satisfactory than that of Dr. Williams. By its use he had been enabled to make extensive incisions through the skin, and perform various operations without pain. Its action upon the skin is as certain as upon the mucous membranes.

DR. W. O. ROBERTS stated that his experience with it had not been at all uniform. In some cases it acted admirably, while in others it failed. In operations about the anus, it had no effect at all; but in the treatment of strictures of the urethra, inflammations of the prostate, etc., it acted with certainty.

DR. T. B. SCOTT inquired with reference to the certainity of disinfectants, what degree of exposure a physician would be justified in undergoing before attending an obstetric case.

DR. T. A. REAMY, of Cincinnati, being called upon to answer this question, remarked that the statement of Prof. Volkmann, as repeated by the essayist, that one could go with safety from the dissecting room to attend an obstetric case was not so remarkable as it appeared, inasmuch as it has been repeatedly demonstrated that the germs that infest the dead body are not the same as produce infectious diseases. In proof of this, reference was made to the reports of cases in the late work of Dr. Lusk. The danger is not going from the dead-house, but from the living-house. Can a surgeon go from a case of so-called puerperal fever to a case of confinement? Under no circumstances should a physician in regular attendance upon an infectious case attend a case of labor; but the surgeon who is accidentally called to see such a case, may with safety attend a confinement upon this one condition: It is imperative that, as soon as he shall return from the case of infection, whether he shall have come into direct contact or not, he shall remove from his body every article of clothing, without exception. He must then take a warm bath, being thoroughly scrubbed and shampooed; then another bath in water containing a solution of the bichloride of mercury, or as much carbolic acid as the skin can bear. Then let him don an entirely different suit. This must be done at once, and not several hours after exposure to the contagion. Then, and then only, may he attend a confinement. A case illustrative of this was reported.

A paper on

ORTHOPÆDIC SURGERY

was read by DR. A. M. VANCE, of Louisville. Infantile paralysis is productive of nearly half the cripples we see upon our streets. Such being the case, it is important that we should be possessed of the best possible method of restoring these deformities. The ability to cure them by the ordinary methods is almost *nil*. The apparatuses are usually so cumbersome and so painful as not to be borne by the little cripples, and are cast aside. Brief reference was then made to the leading operations that have been made or suggested for such deformities. The reporter had adopted the plan of exsecting the joint or angle of bone deformed, and fixing the ends of the fragments so as to secure ankylosis in the most serviceable position. Several cases were reported, in which, after deformities of the ankle, knee, and hip the result of infantile paralysis, excellent results were obtained from the operation.

DR. A. W. JOHNSTON, in making the report of the Committee on

THE SURGERY OF THE GENITO-URINARY ORGANS,

spoke first of the dividing of strictures of the urethra, commencing at the division of the meatus and proceeding backward. One of the most important discoveries in this direction of late years, was that of the relation which exists between the calibre of the urethra and the external diameter of the penis. With regard to the dilatation of these strictures, he agreed with Dr. Otis, that "if you want to get rid of a stricture, you must stretch it to its utmost extent, and cut it while on the stretch." This is the treatment for most cases, but still there is a field for the rapid dilator. Brief reference was made to inflammatory affections about the orifices of the seminal ducts, prostatic, and vesical calculi. With reference to the latter, the opinion was expressed that in the near future, the man who operates for stone, will employ the method of crushing, and rapid extraction, or abandon his practice.

The subject of the next paper was

THE REPORT OF A CASE OF LIGATURE OF THE SUBCLAVIAN ARTERY IN THE THIRD PART OF ITS COURSE, FOR TRAUMATIC ANEURISM, WITH SUBSEQUENT INCISION OF THE SAC AND RECOVERY,

by DR. L. S. MCMURTRY, of Danville. The patient was a robust man, aged 30 years, who, thirteen months previous to the operation, received a pistol-wound of the shoulder, the ball passing deep in the vicinity of the joint. In a few weeks a small lump appeared in the axilla, which increased in size until at the time of operation, thirteen months afterward, it had reached the dimensions of a child's head. The tumor occupied the entire axillary space, and had burrowed up beneath the pectoral muscles. Paralysis of the arm, forearm, and hand resulted from the pressure on the brachial plexus of nerves, so that this member hung useless at the side. The operation was performed two days after the patient called for advice. A silk ligature was passed around the subclavian artery at the external border of the anterior scaleni muscles. Pulsation was at once arrested in the tumor, and never returned. The radial pulse, which before the operation was feeble and fluctuating, was annihilated. The patient made a prompt recovery without accident or complication. On the twenty-first day, the ligature came away. One month afterwards, the patient returned home and was not seen for four months. After the lapse of this period, the patient again presented himself. The tumor had materially decreased in size and was without pulsation or tenderness. The pressure on the plexus of nerves remained with the consequent paralysis. It was then determined to extirpate the tumor. The patient being anæsthetized, an incision was made and a ligature thrown around the axillary artery on the distal side of the tumor. The tumor was then laid open, the clots removed, and the cavity cleaned. The patient is now making a good recovery, and will soon be able to resume his occupation as a farmer. The speaker said that when the conditions are considered it is not surprising that ligature of the subclavian for axillary aneurism is followed by the frightful mortality of 48 per cent. The operation just described, although embodying the principles of the Hunterian operation, is not far removed from the method of Anel. Indeed, when, as in the case reported, the aneurism extends above the acromial thoracic branch, the circulation through the sac is completely arrested by the ligature. Hence suppuration of the sac and secondary hemorrhage are to be anticipated. Again, the ligature is placed in the vicinity of large branches. These facts explain the high death-rate after the operation. The case reported is an illustrative one and the type of a class of circumscribed traumatic aneurisms resulting from wound of the coats of the arteries. The aneurism in these cases approaches in character the pathological form of the disease, with this important exception, that the coats of the arteries above and below the tumor are not involved and are free from disease. It is this feature which makes this class distinct from idiopathic aneurism so far as prognosis and treatment are concerned. In eight cases of this class cited by Erichsen—aneurisms of the axillary artery resulting from stabs and gunshot wounds treated by ligature of the subclavian—not one fatal result occurred.

DR. W. O. ROBERTS reported the case of a man who was stabbed just above the clavicle. Slight hemorrhage occurred at the time, but it was observed that but little pulsation was perceptible at the wrist, and the arm of the same side was paralyzed. The opposite pulse was feeble and beating at the rate of 140 per minute. When he first saw the case, the wound had healed and there was no enlargement. Upon examination of the chest, the apex-beat of the heart could be distinctly felt just below the right nipple, while percussion of the left side elicited flatness throughout. The man died twenty-four hours after. The autopsy revealed the fact that the knife had penetrated the scalenus anticus muscle and punctured the vessel. Around the seat of puncture was a small traumatic aneurism which had ruptured. There was a large opening into the pleura, and this whole cavity was filled with blood, the lung being pushed back against the thoracic wall.

Another case was that of a man with a large osteo-sarcoma of the shoulder, which was removed by disarticulation at the shoulder-joint. There was no involvement of the scapula or shaft of the humerus. During the operation very little hemorrhage occurred. The patient did well until the fourteenth day, by which date the wound had healed through the upper two-thirds. Then a slight hemorrhage occurred. Six hours later, there was a considerable gush of blood, which had to be arrested by pressure upon the subclavian. The original wound was then opened, and the hemorrhage was proved to be from the axillary artery. This was ligated *en masse*. Five days later, the hemorrhage again started and the axillary artery was ligatured, with the result of completely arresting the bleeding for two weeks. Then a slight hemorrhage occurred, but was finally controlled by pressure.

DR. M. F. COOMES read the

REPORT OF THE COMMITTEE ON OPHTHALMOLOGY,

in which he reviewed seriatim the more prominent drugs that are employed by the ophthalmologist, with their uses. Nothing especially recent was reported. Among other recommendations, the author advised the use of a solution containing eight grains each of atropia

Digitized by Google

and morphia in the eyes of delicate females suffering from what he desired permission to call sympathetic glaucoma. The speaker thought the use of the jequirity bean a dangerous procedure at best, and had not himself ventured to try it.

DR. W. CHEATHAM remarked that the term chosen by the author for the affection of the eyes of nervous females, whatever it might be, was a peculiarly unhappy one even if the treatment be proper, for it is a well-known experience that atropia will of itself produce glaucoma. Either the name of the affection should be changed or a more harmonious treatment chosen.

DR. E. WILLIAMS, of Cincinnati, considered inoculation with jequirity as dangerous as inoculation with the virus of gonorrhœa, and not nearly so certain in its results.

AFTERNOON SESSION.

DR. J. A. STUCKEY, of Lexington, exhibited a patient who had received a severe injury to the abdomen by being crushed between the draw-head of a locomotive and that of a freight car. The coupling-pin, weighing seventeen pounds, had been forced through the abdomen, entering at a point about midway between the umbilicus and anterior superior spinous process, and passing out at a corresponding point in the lumbar region. The rent was a large one, and showed marks of having but recently healed.

THE REPORT ON OPHTHALMOLOGY

was read by DR. DUDLEY S. REYNOLDS, who chose as his subject: *The Sources of Error in the Operations Intended to Cure Squint.*

It is necessary, he began, before arriving at any conclusion with regard to the treatment of a persistent squint, to make a thorough investigation of the case, in order to recognize what are the real causes of the trouble. Although there had been a great many speculations concerning this, Donders, in the early part of this century, was the first to recognize the more important causes of it. Graefe was the first to recognize the importance of the discovery, and to apply to it a better mode of treatment than had been employed. The reporter then reviewed the various causes of strabismus: errors of refraction and accommodation, troubles of nutrition, troubles in the sensorium, opacities of the cornea, affections of the coats of the eye or of the vitreous humor, etc. For the relief of such cases, it was recommended first of all to relieve whatever errors there might be in the accommodation by the use of properly adjusted glasses. The operation for squint should not be made unless the affection is single. After describing in brief the methods of operating, the author concluded with the advice to treat all squints as soon as possible after they begin to develop, the operative procedure being reserved for cases which have existed too long to be relieved by other means.

DR. CHEATHAM remarked that he made it a rule never to operate upon these cases until the child has become old enough to wear glasses for the correction of the difficulty, unless the sight is failing rapidly.

DR. E. WILLIAMS thought that the cases of complete recovery from squint are not numerous. The result from alternating squint more frequently completely recovers than single squint. There is some etiological element in many cases of squint which is not explained by reference to errors in refraction. There seems to be a want of natural balance between the muscles.

ACUTE CATARRH OF THE MIDDLE EAR, AND ACUTE SUPPURATION OF THAT ORGAN,

was the subject of the report on Otology, by DR. W. CHEATHAM, of Louisville.

To bad management can be traced nearly all the chronic cases of suppuration from the middle ear, and the two are in a great measure the cause of many cases of great suffering and finally death. The paper was for the most part clinical, embodying the reports of a large number of cases that had come directly under the observation of the author. For the relief of acute inflammation of the middle ear with severe earache, the speaker recommended the use of the aural fountain-syringe or douche, with plenty of hot water, its use to be continued for some time. The point of the tube should be long enough to pass well into the ear. In conclusion, the hearers were cautioned against the use of poultices. They should never be used until all other measures have failed.

THE REPORT ON PHARMACY

was read by DR. J. P. THOMAS, of Pembroke. It began with a review of the leading discoveries in the field of materia medica during the past two years, then passed to the consideration of the leading pharmaceutical preparations that have of late appeared. The author strongly condemned the practice of too many of our manufacturing pharmacists, who devise a new remedy or preparation and procure for it a list of recommendations from unreliable sources, giving it the appearance of having been proved.

DR. J. A. LARRABEE, of Louisville, then read the report of the Committee on

DISEASES OF CHILDREN.

The relations of malnutrition and pneumonia severally to the etiology of children's diseases were first considered; then the more common factors of bad hygiene. While we do not see the sad pictures in the faces of children in this country that are witnessed in foreign countries, it will not be long before restraining legislation will be required by such a condition of affairs. Children should be prevented from engaging in work in shops at too tender an age.

The question of feeding is one of the most important we have to consider; in large institutions it is of the utmost importance. As high as ninety per cent. of mortality has been reported from some of the foundling hospitals, the majority of which was due to improper feeding. In the hospital at Louisville, where mother's milk is alone used, the mortality has been but five per cent. No perfect substitute for this has yet been devised. Another great error is the overfeeding of children—a very frequent source of trouble.

Cholera infantum was next considered. In referring to its etiology, the author remarked that the term thermal, as applied to the disease by Dr. Wood, was scientifically correct, inasmuch as it is more closely allied to sunstroke than to any other affection. This was proved by the result of the therapeutics applied to it by the same author.

The treatment is all-important. Hypodermatic medication should be almost exclusively resorted to, giving

Digitized by Google

in the early stage a solution of morphia and atropia. A single injection of the proper quantity will, in most cases, cause a halt of the symptoms, even when the child is in a state bordering on collapse. The salicylates of lime and soda are the best remedies that have been proposed.

Diathesis and cachexia are to be carefully considered in all cases. Many a child is lost while its disease is properly treated by its name, because the peculiar diathesis is not recognized.

Nothing is more frequent in childhood than fever. It is not, however, as a rule very severe. Most fevers have their origin in the intestinal tract. The essayist held the opinion that most cases of malarial and intermittent fevers reported in children are in reality cases of typhoid. The reason that infants so seldom have typhoid fever is not because of the supposed non-development of the Peyer's glands, but because, as proposed by Gebhardt, the poison of typhoid fever enters the system through drinking-water, and infants drink less water than adults or children. This view is supported by the fact that typhoid fever occurs most frequently at the age when children drink the most and with the least discrimination of water.

Diphtheria, its etiology and treatment, was made the subject of especial comment; and a case was reported in which tracheotomy was followed by recovery, in a case of croup. No advance, however, has been made in the treatment of this disease.

In conclusion, he remarked that more learning and less medicine is needed in the treatment of the diseases of children. Plenty of good food, fresh air, sunshine, and good nursing, with now and then a dose of castor oil, is about all that is required to raise a child.

DR. WEBB inquired more particularly with regard to hypodermatic medication, especially with reference to the dose for an infant. Several years ago he had employed this method in treating a case of this kind, with the most satisfactory result.

DR. HOWARD remarked that the line should not be drawn between children raised on the bottle, but between children raised in the city and those raised in the country. We do not kill them that way, he said, in the country. He would prefer the chances of raising a child by the bottle in the country to letting it nurse a delicate mother.

DR. P. B. SCOTT said that the chief reason for the greater mortality of children raised in the cities over country children lies in the fact that in the country there is plenty of good milk and fresh air. He thought the closest line should be drawn around the feeding of children, both as to the quantity and the quality of the food.

With reference to the hypodermatic medication of children, he said that the same remark had been made by the essayist at the County Medical Society, and with a sort of "eureka" air. He had employed the method some years ago with success, but he did it with fear. He was further curious to know what advantage could be derived from the combination of morphia and atropia. Morphia is, to say the least, one of the most dangerous remedies that can be used in childhood. It should not be used in combination with other remedies, but given separately.

DR. WILLIAM BAILEY remarked that the subject of feeding might be summed up in the statement that the most direct way of starving a child is to overfeed it. He further asked, is not the real cause of the symptoms resembling inflammation of the brain in cholera infantum anæmia of the brain? If this be true, we should abstain from the administration of the bromides, but rather give opium and remedies which tend to congest, and keep the head low.

DR. PINCKNEY THOMPSON thought the greater part of the blame for diseases of children in cities lies at the door of unhealthy mothers. As far as the lacteal secretion is concerned, the woman can be compared to any other animal. If an animal is kept constantly irritated and restless, its milk is of no nutritious value, and just so with a weak, nervous, irritable woman.

DR. LARRABEE, in concluding the treatment, expressed agreement with the statement that anæmia of the brain is the cause of the cerebral symptoms of cholera infantum. It reply to the inquiry about the dose of morphia and atropia, he stated that he used the hypodermic pellets containing one-fourth of a grain of morphia and one-sixtieth of a grain of atropia, making a solution at the time of using, and injecting enough of the solution to contain one-two-hundredth of a grain of morphia and about one-six-hundredth of a grain of atropia. This, for an infant under a year.

DR. W. O. ROBERTS, of Louisville, read a paper on

HERNIOTOMY,

containing a report of a large number of cases, illustrating the different modes of operating and their relative advantages.

EVENING SESSION.

DR. J. MORRISON RAY, of Louisville, read a paper on

WOUNDS OF THE ANTERIOR SEGMENT OF THE EYEBALL.

A number of cases of this accident were reported as having come under the observation of the essayist at the Manhattan Eye and Ear Hospital, New York. The points raised had reference to the treatment and its results. The cases illustrated for the most part the great extent to which the reparative process may operate when but little interference is made.

DR. CHEATHAM then read a paper entitled

NEURO-RETINITIS ALBUMINURICA.

After reporting several cases in which the lesions about the optic disk and retina could be readily recognized with the aid of the ophthalmoscope, he described the characteristic optic lesions found in descending neuritis. Retinitis is frequently associated with Bright's disease occurring, according to the best authorities, in about seven per cent. of all cases, and most frequently in the cirrhotic kidney. The micro-pathological changes in the retina were then described at some length, showing that the lesion is a combination of cirrhotic proliferation of connective tissue and fatty degeneration. Several illustrations were, at the close of the report, thrown upon a screen with the magic lantern.

PRIMARY LATERAL SCLEROSIS OF THE SPINAL CORD

was the title of the next paper, by DR. J. B. MARVIN, of Louisville.

Digitized by Google

This affection is rare, and has been described only recently. It comes on gradually, and is symmetrical in its development. The sclerosis is not a secondary degeneration due to any lesion in the cord or brain. It is a disease of adult life, occurring between twenty and fifty, and more frequently in males than in females. The real cause is unknown, but it is thought that the neurotic temperament plays an important part, and probably syphilis does the same. High fevers, especially typhoid, are among the causes. Grundelli, of Rome, reported eleven cases occurring in the vicinity of that city. It seems usually to attack robust individuals. It is attended with loss of power, and muscular rigidity and twitchings, and an increase, at first, of the muscular reflexes. The patients are well nourished, and there is no disturbance of coördination. There are no sensory disturbances, and no disturbances of the vesical or rectal muscles, showing that the lesion must be limited to the lateral tract of the cord. In the few post-mortems that have been had, little or no evidence of disease has been obtained.

The disease was first described by Charcot and Erb, and by Seguin in this country. The only specimen supposed to be in existence, was exhibited at the last International Congress, and is the property of Drs. Dreschfield and Morgan, of England. The disease seems to commence in the connective-tissue fibres, compressing the nerve-fibres, and ultimately destroying them. The symptoms occur much more frequently as a secondary affection.

The diagnosis of lateral sclerosis is easy, the only question being, Is it primary or secondary? It is in practice most frequently confounded with transverse myelitis. It is probably the most chronic of all spinal affections, for it does not of itself shorten life. It however produces serious complications. It may extend to the anterior columns, causing paralysis, which in turn gives rise to bedsores, malnutrition, and finally death. As regards recovery, the pathological changes would appear to preclude the possibility of it, but such cases have been reported.

At the conclusion of the report, several photographic preparations of the spinal cord, in health, in posterior sclerosis, ascending myelitis, and finally in lateral sclerosis, were thrown upon the screen. The microscopic appearance of the specimen from the case of Dreschfield and Morgan was thus demonstrated. A specimen prepared by the author from his case was then shown under the microscope, exhibiting (though not to the same degree) the same lesion.

DR. ORPHEUS EVERTS, of the Cincinnati Sanitarium, College Hill, Ohio, read a paper on

OVERWORK AS A CAUSE OF INSANITY.

The paper began with a physiological study of work and overwork; the natural relation between work and rest. Few cases are brought to an asylum without the explanation that the individual has overworked. Such an explanation serves not only to flatter the vanity of the patient and his friends, but also thoroughly to conceal the real cause. Several cases were reported which illustrated in a striking degree what was meant by this. Intemperance and excesses of various kinds were shown to be the cause in cases where the habits of the individual were supposed to be the most exemplary. In conclusion, it was asserted that as a cause of insanity, overwork occupies a place of little importance. This conclusion was arrived at after many years of experience in that branch of practice.

DR. M. F. COOMES remarked that, in his opinion, a great many cases of insanity are due to inanition, caused by the habits of business men, who closely apply themselves during the entire day without giving themselves time to eat and digest their meals. It should always be a rule never to go to bed hungry.

STRYCHNIA AND MERCURIC BICHLORIDE IN THE TREATMENT OF PHTHISIS

was the subject of a paper by DR. T. D. FINCK, of Louisville. Several cases were embodied in the report, in which these remedies had been given in the dose of a thirty-second of a grain three times daily, with the most satisfactory results. In one the process of disintegration had already begun; in all the fever and night sweats disappeared, the appetite returned, nutrition increased, and all the symptoms but the cough were relieved. A brief review of the probable physiological action of the remedies was given in conclusion.

DR. D. S. REYNOLDS directed attention to the recent reports of German investigators as to the power of the bichloride of mercury in restraining disease, and further to the fact that ever since the discovery of the bacillus tuberculosis it has been found that that germ existed in large numbers in the lymphatics, and in the secretions of the air passages of individuals suffering from the so-called post-nasal catarrh. The speaker had of late observed that the constitutional use of the bichloride of mercury would in a short time clear away this affection.

DR. STUCKEY, of Lexington, reported good results from the use of this treatment.

DR. LETCHER reported that he had found the bichloride very useful in arresting the diarrhœa of phthisis.

At the close of the session a banquet was tendered the guests; a very enjoyable evening was spent.

FRIDAY, JUNE 26TH.—THIRD DAY.

The greater part of the last session was occupied with the appointing of committees and delegates to various societies, and hearing of reports.

The Committee appointed to consider the subject of

STATE BOARDS OF EXAMINERS

reported that the conditions stated in the communication were, in the State of Kentucky, impracticable. They recommend, however, that the legislature be petitioned to pass an act requiring all physicians practising in the State to register in the Clerk's office in each county, a diploma from a reputable medical college. This could be done, but anything more stringent would fail.

DR. JOHN G. CECIL read a paper on

MASTITIS.

The principal recommendations of the paper referred to treatment. The author advocated rest as the best method of treatment, and superior to all applications. The milk-pump must not be used. The idea that the child must be put to the breast immediately is an erroneous one, and capable of doing much toward the development of inflammation.

Digitized by Google

DR. THADDEUS A. REAMY endorsed the leading points of the paper, and reported twenty-two cases occurring at the Good Samaritan Hospital, Cincinnati, where the child was taken from its mother shortly after birth. In eight he had employed the belladonna plaster; in fourteen, nothing; in none of them did an abscess develop. Fissures are a cause of mastitis, but they should be let alone.

DR. F. C. WILSON, of Louisville, exhibited several new inventions for the operation of tracheotomy. One of them for which he claimed especial advantages was so constructed as to admit of its being forced into the trachea at one plunge. A number of other patterns were shown. The speaker stated that his object was to elicit suggestions that might lead to improvements.

FRACTURES OF THE FEMUR

was the title of a paper by DR. P. S. CONNER, of Cincinnati.

The frequency of its occurrence, the gravity of the often-arising complications, and the rarity of its satisfactory repair, give never-failing interest to the subject. Occasionally met with in middle life, possibly even in childhood, it is one of the common accidents of old age. For this there is good anatomical reason in the increased brittleness of the bone, dependent upon senile rarefaction, and not, as is commonly stated, upon any change in the relation of earthy and animal constituents. The break may be located anywhere between the head and the intertrochanteric lines, the degree of obliquity depending in part upon the structure of the neck, but in great measure also upon the direction of the breaking-force. The literature of the profession is full of the discussions, at times acrimonious, upon the subject of intra- and extra-capsular fractures, their relative frequency, differential diagnosis, and appropriate methods of treatment. But practically this is of little or no value. It is impossible to tell in a given case, except by inspection of the joint, whether the fracture is in part within or partly without the capsule. Owing to the peculiar anatomical relations of the capsule, all are intracapsular in front, but behind some are and some are not, and, so far as the speaker knew, there is no way of determining during life which class of fractures he has to deal with. The wise course is to stop with the determination of the existence of a neck fracture, and to treat all cases as if complete repair by bone might be expected.

Dr. Conner then objected to the common explanation of the occurrence of ligamentous union on the ground of the deficient blood-supply to the upper fragment. If sufficient to maintain the health of the bone, it should be sufficient for the requirements of repair. This, with the other explanation that there is present too much synovial fluid, can have little effect in the prevention of union. The all-important cause is want of proper apposition of the fragments, and failure to keep them quiet—one or both. Best adapted to this end is the immovable dressing. This, to satisfy fully the requirements of the case, must embrace not only the thigh but the pelvis also, or at least half of it. And just here lies the difficulty in applying such dressings. The plaster-of-Paris dressing is for many reasons the best, but this must be applied so as to exert no undue pressure on the region of the genito-crural furrow. To apply it properly over the whole gluteal region and hold it there, requires an additional girding of the upper part of the opposite half of the pelvis, or the carrying of the supporting dressing obliquely around the body, across the opposite lumbar region. Even if the immovable dressing is properly applied, there is always a chance that in consequence of the wasting of the limb, sufficient loosening will occur to permit some displacement of the fragments, to prevent which, the weight and pulley treatment may be added.

Applied early, the immovable dressing saves the patient much suffering, and permits with safety all necessary changes of position. From increasing experience, the author has become convinced that by the careful application of this dressing we can secure better results to our patients and to ourselves than in any other way, and he further believes that in a large proportion of cases recovery will take place with a limb of good functional value. In conclusion, it was suggested that perhaps in the future it will be clearly shown that the rare occurrence of bony union in the past has been simply because the fragments of the broken femoral neck have not been kept steadily in apposition, but have been allowed to separate and play upon each other so that only an imperfect ligamentous repair has been possible.

DR. R. M. FERGUSON, in a paper on

THE TREATMENT OF CROSS-EYES,

considered chiefly the classes of cases fit for an operation and those which should be treated by other methods. Little was added to the remarks already made upon this subject. A thorough knowledge of all features of the case was deemed of the greatest importance.

After appropriate votes of thanks to officers and the proprietors of the resort, the Association adjourned to meet at Winchester, on the last Wednesday of June, 1886.

MICHIGAN STATE MEDICAL SOCIETY.

Twentieth Annual Meeting, held at Port Huron, June 10 and 11, 1885.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, JUNE 10TH.—FIRST DAY.

MORNING SESSION.

THE meeting was called to order by THE PRESIDENT, DR. DONALD MACLEAN, at 10 A.M., and GEN. WM. HARTSTUFF delivered an address of welcome.

DR. O. B. CAMPBELL then read a paper on

MIGRAINE.

He said that etiologically migraine is a "constitutional neurosis," with a strong hereditary tendency. Its symptoms are caused by vascular disturbances.

We have three elements: 1. A tendency (often hereditary) to nervous exhaustion. 2. Spasmodic anæmia 3. Irritative hyperæmia.

When an attack is impending croton chloral, caffeine, etc., will sometimes abort it. In the spasmodic stage nitrite of amyl, or morphia hypodermically, is of service. In the hyperæmic stage a combination of ergot, hydrobromic acid, and caffeine should be used. The

Digitized by Google

neurotic element of the disease should be treated between the attacks by cannabis indica.

DR. SMART, of Hudson, advocated perfect rest for the patient in a dark room away from noise. The prolonged use of small doses of arsenic as a tonic and alterative he believed is beneficial. Cannabis indica, hydrate of chloral, nitrite of amyl, and bromo-caffeine, bearing in mind the physiological effects of each, may often be used to advantage.

DR. H. O. WALKER, of Detroit, then read a paper on

EXTERNAL PERINEAL URETHROTOMY,

with a report of five cases that he had operated upon successfully since the last meeting of this Society. The details were dwelt upon at length, emphasizing the necessity of thoroughly dividing all strictures the entire length of the urethra, together with sufficient dilatation of the prostatic urethra, so as to admit the index finger and permit of exploration of the bladder. He also exhibited a new urethrotome with filiform attachment, a prostatic divulsor, and beaked triangular-shaped urethrotomy knife, which he had devised for this operation.

AFTERNOON SESSION.

DR. T. A. MCGRAW, of Detroit, presented two patients, from one of whom he had removed the left parotid gland, and from the other had removed the left clavicle. The results in each case were most excellent.

DR. LUNDY, of Detroit, then read a paper upon

IRITIS: ITS RELATION TO THE RHEUMATIC DIATHESIS, AND ITS TREATMENT.

His views did not coincide with those recently expressed by Sir Jonathan Hutchinson regarding the extreme rarity of iritis in connection with either acute or chronic rheumatism. The author had frequently observed iritis in persons who were either actually suffering from rheumatism, or who were of an undoubted rheumatic diathesis. While Sir Jonathan Hutchinson's views might be correct so far as observation in Great Britain was concerned, they do not, in the author's opinion, agree with the facts observed in this country. Several interesting cases were reported in which great benefit was obtained from the free administration of sodium salicylate. When given in large doses the influence of the salicylate in controlling pain was remarkable. In some instances leeches, atropine, and moderate doses of sodium salicylate had no influence in controlling pain, but when large doses of the salicylate were given—forty to fifty grains—the pain was relieved as if by magic, and seldom returned. The author found the dilatation of the pupil by atropine much more easily attained after the use of large doses of the sodium salicylate. Whenever there exist great ciliary pain and irritation, it is difficult to dilate the pupil. This is the case even if no iritis exists. Whatever relieves the pain and irritation in the ciliary region removes two influences which militate powerfully against the action of a mydriatic. This the salicylate of sodium will do when the iritis occurs in a rheumatic subject, but it is necessary to produce the fullest physiological action of the drug. Smaller doses may suffice if the joints alone are involved, but when iritis exists there is "danger in delay." While internal medication is of great importance, when iritis is due to some constitutional or general disease, the local treatment must always be of the first importance. Atropine, four to eight grains to the ounce, should be instilled four to six times a day. We should aim to dilate the pupil as quickly and as fully as possible. If the pupil is well dilated, no adhesions will form between the posterior surface of the iris and the lens capsule. When the pupil is well dilated the iris is compressed into a comparatively small space, and the blood is, so to speak, squeezed out of the vessels. The effect upon the iritic inflammation is the same as would occur from cutting off the blood-supply from inflamed parts elsewhere. The abstraction of blood from the temple by means of the artificial leech is also advisable. Absolute rest of the eyes is imperative, and they should be protected from light.

DR. G. K. JOHNSON, Chairman of the Committee on

REORGANIZATION OF THE SOCIETY,

then rendered his report. It recommended amendments to the Constitution and By-Laws now in force, providing for making the Society a delegated body, and for Sections on Medicine, Surgery, Obstetrics, etc., to hold in certain cases separate sessions. The report was accepted and laid over one year, under the rules.

DR. J. H. CARSTENS then read a paper on

STERILITY.

He discussed very ably the causes of sterility and its treatment, and claimed that its cause existed in the male oftener than is generally supposed, and that where no perceptible cause existed in the wife the cause should be looked for in the husband.

DR. DUNSTER, in discussing the paper, said that the subject had been so well treated that there was but little left to be said upon it. The author had, however, omitted to mention vaginismus, which was not an unfrequent cause of barrenness. The secretions of the vagina are sometimes fatal to the spermatozoa; that many of the physical conditions causing sterility are beyond the control of the physician and surgeon.

DR. OCTERLONY, of Louisville, said a non-retentive vagina, such as sometimes exists as a result of a lacerated perineum, and again in cases where no apparent disease exists in either the male or female, the cause might be found to be the passage of the semen with the urine. Want of vitality in the man or woman, or both, or certain idiosyncrasies, may be causes.

EVENING SESSION.

The President announced the following Committee on

NOMINATION OF OFFICERS

for the ensuing year, viz.:

J. H. Bennett, of Coldwater; Eugene Boise, of Grand Rapids; E. Snow, of Dearborn; C. J. Lundy, of Detroit; G. F. Heath, of Monroe.

The President then delivered his

ANNUAL ADDRESS.

He began by giving something of a history of his medical and surgical training, and he thought that a man who had been a teacher for years, and a successful practitioner of medicine and surgery for twenty-four years, was entitled to an opinion, and the right to express it. He related some cases which had come to him

Digitized by Google

for treatment, and supported the idea which had been advocated regarding the establishment of a central hospital for Michigan. This hospital should be located where it would do the most good for the masses of the people. It should be supported entirely by the State, and open to all people on equal terms. He was very grateful to the profession of Michigan, and more especially to the Michigan State Medical Society, for electing him as the President of the Society.

THURSDAY, JUNE 11TH.—SECOND DAY.

MORNING SESSION.

DR. SMART presented a report for the Committee on

MEDICAL LEGISLATION,

with a draft of a bill, and recommended its endorsement.

As a number of amendments were proposed and as considerable time was likely to be consumed in its discussion, on motion of Dr. Whelan, a committee of five was appointed by the President to revise it, and report upon it at 2 o'clock P.M. The President appointed as such committee Dr. Whelan, Dr. Nothingham, Dr. Shepard, Dr. Sharley, and Dr. Smart.

DR. SMART moved that a Committee on State Sanitation be instructed to take such means as are necessary to secure the passage of a bill by the State Legislature, forbidding the

SALE OF NOSTRUMS AND PATENT MEDICINES

unless the composition is on the labels. Carried.

PROF. A. B. PRESCOTT, of Ann Arbor, then read a thoroughly practical paper entitled

SHOULD PROPRIETARY MEDICINES BE REQUIRED TO GIVE AN ACCOUNT OF THEIR CONTENTS.

He took a plain, straightforward view of the matter, and thought that a person who bought any article of merchandise was entitled to know just what he bought, and that it was of good quality and not dangerous to life or health. In France, the maker of any compound is required to bring it before the Academy of Medicine for chemical analysis and therapeutic test before it can be placed before the public, and it seemed to the writer that the people of the State of Michigan were entitled to protection from the imposition of designing mixtures of medicines just as much as any other people, and he hoped that Congress and the Legislatures of the several States would take the matter under consideration.

AFTERNOON SESSION.

DR. VAUGHAN moved that Dr. Hingston, of Montreal; Dr. Octerlony, of Louisville; Dr. Morse, of Ohio; Dr. Moorhouse, of London, Ontario, be elected

HONORARY MEMBERS

of the Society. Carried. Dr. H. E. Smith moved that Dr. Samson, of Ontario, be elected honorary member. Carried.

The Committee on Nominations presented the following list of

OFFICERS FOR THE ENSUING YEAR:

Vice-Presidents.—Drs. P. D. Patterson, J. B. Griswold, J. H. Carstens, and A. W. Alvord.

Treasurer.—Dr. A. R. Smart.

Members of the Judicial Council.—Drs. J. H. Bennett, Wm. Brodie, and E. S. Dunster.

On motion, the report was accepted and adopted.

DR. BENNETT in a few complimentary remarks nominated Dr. E. P. Christian, of Wyandotte, for

PRESIDENT

for the ensuing year. Dr. Snow supported the nomination. On motion, the Secretary was instructed to cast the vote of the Society for Dr. Christian, which duty being performed, President MacLean announced that Dr. Christian was unanimously elected President.

MISCELLANEOUS BUSINESS.

THE SECRETARY and TREASURER then rendered their reports. A balance of $914.17 is in the Treasury.

DR. I. E. BROWN moved that the usual *honorarium* of $100 be voted the Secretary for his services during the past year. Carried.

DR. HEMENWAY, of Kalamazoo, then read a paper upon the

HYGIENE OF STUDENT'S EYES.

He said that from the continued use of the eyes at near vision, myopia, congestion, and inflammation of the eyes, atrophy of the coats posteriorly, and even soft cataract may result.

To keep the eyes in good condition they should be used at near and distant vision alternately.

They should be used less at near vision by those in poor health and by the young, than by the strong, vigorous, and more advanced in age.

Those who are obliged to use their eyes much at near vision, should have a pair of suitable convex lenses, and as soon as pain or a tired feeling about the eye give indication that the organs are being overtaxed, the spectacles should be used. By use of such lenses the eye is put in a state of rest, and myopia and other troubles may be prevented.

Myopia when once acquired can never be cured.

The general health must be cared for, especially the alimentary canal. The eyes will not do good work while the system is not in good condition. As soon as ocular disease shows itself, it must be carefully treated.

DR. C. M. STOCKWELL, of Port Huron, then read a paper on

FUNCTIONAL PARALYSIS (MOTOR AND SENSORY) OF THE EXTREMITIES, DUE TO MALARIAL POISONING.

A record of seven cases was given, six of them were under the writer's care, and were cases observed during the past six years. An analysis of the cases showed:

Various functional disturbances of the nerves in the extremities, shading from a slight coldness and numbness on the one hand to complete loss of both sensation and motion on the other. All four extremities, from the elbows and knees down, were involved in five of the seven cases, the lower extremities alone in one other, and the most of one side in the remaining one. The latter two were cases of both motor and sensory paralysis. The others were chiefly, if not entirely, cases of sensory paralysis. The region over the mental foramen was implicated in three cases; the tongue was attacked in one. The attacks, almost without exception, occurred in the spring and fall.

Imperfectly drained surroundings, cold, dampness,

Digitized by Google

over-exertion, and worry, aided in producing the disease and in retarding recovery. Nearly all attacks occurred in the first half of the day. Increase of temperature and pulse was not marked in any case, and almost absent in some. The intellectual faculties were disturbed in no case. No tenderness over any part of the spine could be found. The periodicity was marked, being either quotidian, tertian, or weekly. In one case a paroxysm came on each Thursday morning for eight successive weeks, lasting not over twenty-four hours. In another the paroxysm came on every Tuesday about noon for four successive weeks, besides showing a tendency to recur every other day for one of the weeks.

The cases yielded readily to antiperiodics, and recovery was perfect, and restoration of functions complete.

DR. KIMBALL, of Jackson, invited the Society to hold its

NEXT ANNUAL MEETING

at Jackson.

DR. WHELAN moved that, when the Society adjourns, it be to meet at Jackson, on the second Wednesday of June, 1886. Carried.

After the passage of the usual resolutions of thanks, the Society adjourned at 4 P.M.

NEWS ITEMS.

BOSTON.

(From our Special Correspondent.)

THE INTERNATIONAL MEDICAL CONGRESS.—The following gentlemen have requested to have their names appended to the list of signers to the resolutions adopted in Boston declining to hold office in the proposed Congress as now organized, which appeared in THE NEWS of last week, page 53:

O. W. Holmes, Boston,	G. P. Conn., Concord, N. H.,
William H. Baker, "	F. H. Gerrish, Portland, Me.
David W. Cheever, "	S. C. Gordon, " "
James C. White, "	E. P. Hurd, Newburyport, Mass.,
William F. Whitney, "	Nathan Allen, Lowell, Mass.

THE INTERNATIONAL MEDICAL CONGRESS AND THE MEDICAL PROFESSION OF WASHINGTON.—At a meeting of medical gentlemen, held in Washington, D. C., July 11, 1885, the following preamble and resolution were adopted:

"*Whereas*, Certain changes have been made in the constitution and organization of the Ninth International Medical Congress, which seems to us unwise, injurious, calculated to bring the profession into disrepute, and to endanger the success of the Congress; therefore,

"*Resolved*, That we, the undersigned, decline to hold any position under the said Congress as now organized."

Joseph Taber Johnson,	S. C. Busey,
W. W. Johnston,	H. C. Yarrow,
Swan M. Burnett,	A. F. A. King,
B. F. Pope, U. S. A.,	Frank Baker,
E. Carroll Morgan,	D. Webster Prentiss,
J. Ford Thompson,	S. O. Richey,

D. L. Huntington, U. S. A.

RESIGNATION FROM THE NEW COMMITTEE ON THE ORGANIZATION OF THE INTERNATIONAL MEDICAL CONGRESS.—We are informed that Dr. George J. Engelmann, of St. Louis, a member of the original Committee of seven, has forwarded his resignation to the new Committee.

PUBLIC OPINION ON THE WORK OF THE CHICAGO COMMITTEE.—It was scarcely to be expected that those eminent physicians of Philadelphia, whose action in regard to the organization of the Ninth International Medical Congress we recorded last week, would find themselves alone in the resolve to stand aloof from a gathering which, as is constantly growing more and more manifest, will be an international Congress only in name. As will be seen by our news columns, Boston and Baltimore have promptly followed suit, and, like the Philadelphia resolutions, those passed in Boston and Baltimore are signed by men whose names are indissolubly connected with American medicine. Whether organized action of like significance will be taken in New York and elsewhere, it is impossible to say, but this much is certain, that some of the New York men, whom the new committee of the American Medical Association placed among the officers of Sections, have no sympathy with the ostensible motives—far less with the real motives—which led a little band of malecontents to plot the destruction of the Washington meeting. Even if those gentlemen do not formally express their feelings in the matter, there can be no doubt that they will abstain from any participation in the Washington meeting.

That the wreck of the Congress of 1887 has not been irretrievably wrought, we can see no reason to hope.—*New York Medical Journal.*

This action of the Association can be justified by no reason or argument, and the superlative folly of it is quite beyond the reach of adequate characterization.—*Medical Record.*

The Committee did the work expected of it, and with less malice than would have been possible, but with sufficient thoroughness, we fear, to put an end to the prospects of a successful and creditable *International* Congress . . . Numerous changes and additions were made in the officers and members of Councils of the different Sections. These honors are issued as plentifully as fiat money after a *coup d'état*, and the various geographical divisions of the country are impartially besprinkled with them.—*Boston Medical and Surgical Journal.*

The new Committee has performed the most stupendous work of supererogation ever exacted from a body of intelligent men. We are totally unable to see how the fortunes of the Congress have been a tithe benefited by the changes made. On the contrary, it has suffered immensely in the eyes of all unbiassed thinkers by this unnecessary controversy about representation on Sections and "New Code" principles. As the Congress now stands organized we much doubt its ability to attract that attention as a scientific body it was entitled to. How can those men interested in pure science feel that same interest in the fortunes of an organization handicapped with contentions for offices and ethics, and weighted down with that ponderous body, the American Medical Association? It is truly an unfortunate circumstance which has happened to impair the usefulness of the International Medical Congress. Whilst we still trust that wise councils will prevail, that bitter differences will subside, that men will consent to work together in harmony for the success of the Congress, it seems quite clear to us that the Ninth International

Digitized by Google

Medical Congress cannot take the position it would have assumed under its first organization.

It is a sad commentary upon the status of the profession in America that a petty squabble for a few positions should have marred what had promised to be one of the most noted scientific meetings ever held on American soil. What view our trans-Atlantic brethren will take of this status of the Congress it is not difficult to surmise. We presume that the American Medical Association will enjoy the banquet it has prepared to its own eminent satisfaction, whilst the rest of the profession will look on from a distance. We cannot but deplore the present outlook, and profoundly trust that the final result will be more satisfactory than present indications would seem to warrant.—*Maryland Medical Journal.*

We believe the whole trouble has arisen from personal grounds on the part of a few who were overlooked when the places of honor were distributed. It was purely a fight of the "outs" against the "ins," and now that the "outs" have gained the field, the existence of the Congress is jeopardized.

It cannot be claimed that the American Medical Association at New Orleans represented the medical profession of this country, or if the claim be made it is a laughable one. And it cannot be denied that the American Medical Association, with every similar body in the country, is more or less ruled by coteries and cliques. The situation is a deplorable one for the good name of the medical profession in America. Our European brethren will hesitate to attend the Congress at Washington in very large numbers, for they will have reason to fear that the factional feeling and jealousies of certain members of the "rule or ruin" party in the American Medical Association will carry their fight into the Congress itself.

What is to be done to remedy the trouble, and preserve the good name of the profession of America? We do not know; perhaps the best thing that could be done would be to notify the Executive Committee of the last Congress that, owing to the war ranging in the United States, the next Congress should be held elsewhere, either in Europe or Canada.—*Peoria Medical Monthly.*

However proud the West and South may be of their great lights in medicine, it is a fact which need not be minced that these are not numerous. 'Tis true that we can boast of many learned and brilliant men; but, nevertheless, the fact holds, that our original investigators in medical science, and the writers of our classic medical books, are, with a few exceptions, residents of our eastern coast cities. These are the men who have made the fame which American medicine enjoys beyond the sea, and these are they whom distinguished foreigners will expect to meet at the coming Congress. If, therefore, the names of our most eminent authors and discoverers do not appear upon the published statement of the rules and preliminary organization of the Ninth Congress, we need not look for any distinguished delegation from abroad.

The whole blame must rest upon the shoulders of the American Medical Association, who, after appointing a committee of seven wise and eminent men to arrange the preliminary work of the Congress, should have consented to question their judgment and meddle with their work at the instance of a few disaffected but persuasively eloquent fellows.

At the next meeting of the Association there will doubtless be made a sublime attempt to undo the mischief, but nearly two years will then have been lost, with many, if not all, opportunities for making the Gongress a brilliant success.—*Louisville Medical News.*

NOTES AND QUERIES.

THE INTERNATIONAL MEDICAL CONGRESS.

To the Editor of THE MEDICAL NEWS.

SIR: I ask leave to say that I declined signing the resolutions forwarded by your correspondent in this city in relation to the Ninth International Medical Congress, and published in your issue of the 11th inst., p. 53, because they place the blame of the lamentable state of affairs entirely on the action of the new committee at Chicago; while it seems to me, that committee acted simply in accordance with the stringent restrictions imposed upon it by the unwise and revolutionary conduct of the American Medical Association at New Orleans, in nullifying the action of the first committee, and thus opening the Pandora's box of the countless evils now agitating the American medical profession.

The resolutions passed at the meeting of the medical men in Boston, and published on the same page of your journal, meet with my cordial concurrence. With great respect,

WM. T. HOWARD.

181 MADISON AVE, BALTIMORE,
July 13, 1885.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 30 TO JULY 13, 1885.

AINSWORTH, F. C., *Captain and Assistant Surgeon.*—Relieved from duty at Headquarters Department of Missouri.—*S. O. 93, Department of Missouri,* June 26, 1885.

HAVARD, VALERY, *Captain and Assistant Surgeon.*—Assigned to duty at Fort Wadsworth, New York Harbor.—*S. O. 140, Department of the East,* July 2, 1885.

WYETH, M. C., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Fort Wayne, Michigan.—*S. O. 140, Department of the East,* July 2, 1885.

TAYLOR, B. D., *Captain and Assistant Surgeon.*—Assigned to duty at Little Rock Barracks, Arkansas.—*S. O. 139, Department of the East,* July 1, 1885.

POWELL, JUNIUS L., *Captain and Assistant Surgeon.*—Ordered from the Department of the East to Department of the Missouri.—S. O. 155, A. G. O., July 9, 1885.

BIRMINGHAM, HENRY P., *First Lieutenant and Assistant Surgeon.*—Ordered from Department of Missouri to the Department of the East.—*S. O. 155, A. G. O.,* July 9, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL DEPARTMENT OF THE U. S. NAVY, DURING THE WEEKS ENDING JULY 4 AND JULY 11, 1885.

SHAFER, JOSEPH, *Assistant Surgeon.*—For duty on board the U. S. Receiving Ship "St. Louis," League Island, Pa., July 10, 1885.

BYRNES, J. C., *Passed Assistant Surgeon.*—Detached from the steamer "Powhatan" for duty at Navy Yard, Norfolk, Va.

CORDEIRO, F. J. B., *Assistant Surgeon.*—To the "Powhatan," as relief of Passed Assistant Surgeon Byrnes.

CURTIS, L. W., *Assistant Surgeon.*—To Philadelphia, for examination preliminary to promotion.

DRENNAN, M. C., *Surgeon.*—Placed on waiting orders.

FITZSIMMONS, P., *Surgeon.*—Duty on Receiving Ship "Franklin," Norfolk Navy Yard, continued until July 1, 1886.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING JULY 11, 1885.

FESSENDEN, C. S D., *Surgeon.*—Leave of absence extended sixteen days, on account of sickness, July 1 and 9, 1885.

BENNETT, P. H., *Assistant Surgeon.*—Granted leave of absence for twenty-two days, July 9, 1885.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLVII. SATURDAY, JULY 25, 1885. No. 4.

ORIGINAL ARTICLES.

THE RELATION BETWEEN CHRONIC OTITIS MEDIA CATARRHALIS AND CHRONIC RHINITIS.[1]

BY CHARLES H. BURNETT, M.D.,
OF PHILADELPHIA.

CHRONIC catarrh of the middle ear—*i. e.*, otitis media catarrhalis chronica (non-suppurativa)—is invariably associated with some form of chronic rhinitis. The latter is usually of the hypertrophic form, since only about four per cent. of all cases of chronic rhinitis are of the truly atrophic form. Hence, in rhino-aural diseases, less than four per cent. will be strictly of the atrophic form, because all rhinal diseases are not followed by aural disease. In my investigations, by applying the term atrophy in a wider sense, so as to include fibrous degeneration and sclerotic catarrh, as I shall show, I have found considerably more than four per cent. (nearly 14 per cent.) of rhino-aural cases, which may be classed under the atrophic form. It will be found that the catarrhal processes in the Eustachian tube and middle ear proceed from those in the nares and nasopharynx, and hence partake of their nature, or that they occur simultaneously with them and are relievable by treatment of the nasal disease; therefore, all cases of chronic naso-aural catarrh—*i. e.*, catarrh of the middle ear—may be divided into two classes, viz., the *hypertrophic* and the *atrophic*. Since atrophic rhinitis may be further divisible into the strictly atrophic, in which there is shedding of the epithelium and exposure of the basement-membrane, and those in which there occurs a fibrous degeneration, a form of atrophy subsequent to a hypertrophic process in the cavernous tissues of the nares, it will be found that the atrophic division of naso-aural catarrh is thus further subdivisible, making, as I have thus intimated, the atrophic class more numerous than it would be if limited entirely by the strictly atrophic form of nasal disease. It must also be borne in mind that, though all middle-ear catarrhs are associated with chronic rhinitis, it is by no means true that all cases of chronic rhinitis cause chronic aural catarrh.

There is constantly observed a train of symptoms in the middle ear and nares common to the hypertrophic class, and also certain symptoms common to these parts in the atrophic form. It is my object at this time briefly to point out these common and consistent symptoms, to try to discover what other aurists have observed, and to suggest and elicit modes of treatment of these numerous and important cases of aural disease.

[1] Read at the meeting of the American Otological Society, New London, Conn., July 14, 1885.

It may have been observed that I have said nothing about the faucial and pharyngeal symptoms in chronic aural catarrh. It is because the nasal symptoms are so much more important—because, in fact, the pharyngeal symptoms, in comparison with the nasal, are unworthy of consideration as causative elements in aural disease.

In order to study the relation between chronic nasal, and chronic aural catarrh, I have taken the last fifty-five consecutive cases of so-called chronic catarrh of the middle ear, as they have presented themselves to me in private practice, and I have found that forty-seven of these presented well-marked symptoms of hypertrophic nasal catarrh, and eight cases presented equally distinct features of atrophic rhinitis as previously defined.

The nares in the first group present the well-known appearances ranging from congestion to that of engorged and enlarged mucous cushions upon the turbinated bones, usually the inferior ones, both anteriorly and posteriorly. These are soft in the early stages, but grow paler and harder in the more chronic forms. The hypertrophy may extend to the mucous membrane on the septum narium. There may also be enchondromata and osteomata in such cases.

Those in the first category, the hypertrophic form, so far as concerns the fauces, present chiefly an active follicular pharyngitis; next in order of frequency, follicular pharyngitis undergoing retrogression towards atrophy; next, a relaxed condition with incipient fibrous degeneration, and in some few cases, especially in children, a pharyngitis with enlarged tonsils, producing mouth breathing. In some few cases the fauces are unaffected.

Tinnitus aurium is not a pronounced symptom in this form of chronic aural catarrh, it may be absent, and it rarely becomes annoying; when it occurs it is of a mild type of the hissing quality. The Eustachian tube is less permeable (from the hypertrophy) than in the atrophic and sclerotic forms, as will be shown later. The hearing is not so profoundly affected as in the atrophic class of aural catarrh, and when impaired is much more amenable to treatment.

The appearances of the membrana tympani are very variable. None of them are sharply peculiar to the hypertrophic form of naso-aural catarrh. In this form of chronic catarrh of the middle ear, both the malleus and the membrana tympani may be found to be immovable under the pneumatic speculum, or the membrana may rise and fall beneath such inspection, the malleus remaining fixed. In fourteen cases the membrana was opaque without retraction in both ears. In three instances, one ear being unaffected, the membrana in the deaf ear showed no pathological change. In ten cases the membrana was retracted and opaque. In five cases the membrana was thinned and retracted and the incus was visible. In seven instances the membrana tympani

Digitized by Google

showed no abnormality, but the hardness of hearing was marked. In five instances the membrana was white, thick, and retracted, and in these cases the tinnitus was most marked. It will be shown later that this latter appearance of the membrana is more characteristic of the atrophic form of aural catarrh, in which also tinnitus is a constant and marked symptom. In two cases (associated with enlarged tonsils and mouth breathing in children), the membrana was red and retracted, showing a hypertrophic process in the tympanic cavity. In one instance the membrana tympani was flaccid and thin.

In the *atrophic* class of chronic aural catarrh, the nares are atrophic, their capacity is increased, the mucous membrane over the turbinated bones and septum is pale, dry, and shining, or varnished in appearance in the truly atrophic cases and in the others the mucous membrane is pale and shrivelled with evidences of the previous existence of an hypertrophic process. There is further in the atrophic class a tendency to inspissation and retention of mucus and consequent ozæna. The atrophy is often so great as to permit an easy view of the motions of the soft palate during inspection by anterior rhinoscopy. The pharynx, too, is atrophic, or exhibits a tendency towards that condition, having a glazed or varnished appearance, especially on the posterior wall. In the sclerotic degeneration, also placed in the atrophic group, the fauces may show a fibrous degeneration and sclerosis.

Tinnitus aurium is a most pronounced symptom, and at times of the most distressing quality, in this class of naso-pharyngeal aural catarrh. It is in this group that we find all the distressing cases of tinnitus aurium of the hammering, sawing, harsh quality, associated often with a tendency to nausea and vertigo. In these cases I have observed a constant and curious condition, viz., undue and often excessive patulence of the Eustachian tube. It seems as if the atrophy and consequent widening seen in the nares in these cases, had extended to the Eustachian tube. Inflations, therefore, are disagreeable and often painful, and upon auscultation the air is heard to rush into the middle ear. It has been claimed by some observers (Rüdinger and others), that a sudden, undue, and continued patulence of the Eustachian tube causes peculiar and disturbing subjective sounds in the ear. Some such connection may exist between the excessive tinnitus and the constant atrophic widening of the Eustachian tube in these cases. But, whether the Eustachian tube be less or more closed than normal, resonance of the ear is altered and so-called subjective sounds become audible and annoying. The hearing in these cases is most profoundly affected and least remediable.

In the atrophic aural catarrhs the membrana tympani is more uniform and consistent in its pathological appearances than in the hypertrophic forms. It is either thick, white, and retracted, or it is thinner, but still white and retracted, and in the latter state the incus becomes plainly visible. In those cases in which the membrana is thick, white, and retracted, the precedent hypertrophic process has been most probably excessive, whereas, in the form with the thin and retracted membrana the process probably has been chiefly atrophic from the outset. In one atrophic case the membranes were thick and cutaneous in appearance, and exhibited perforations with cicatrized edges.

Treatment.—The local treatment of these cases, in order to be efficient, must be directed chiefly to the nares. Since the catarrhal process in the ear has its origin in the catarrhal process in the nares, amelioration and removal of the latter will be followed by improvement in hearing, and if the organic changes in the delicate parts of the middle ear have not been too profound, by removal of the deafness.

It will also be found that tinnitus aurium in these cases of catarrhal disease of the Eustachian tube and middle ear, is most relieved by treatment of the catarrhal processes in the nares and nasopharynx. This fact throws force into the argument that tinnitus aurium is a truly objective sound, induced by increased vascularity and the motion of the blood in and near the sound-conducting parts of the ear.

As the congestive state of the vascular tissues near the ear is overcome by treatment, the tinnitus will be found to diminish, and this desired end is often best brought about by local treatment of the nares and nasopharynx.

In some instances the appearance of the membrana tympani becomes, under treatment of the nares and nasopharynx, nearly normal in every way. Whereas, all endeavors to treat chronic catarrh of the middle ear by applications to the external ear surface of the membrana, are worse than useless, since they distort and disturb the membrana and increase the deafness and tinnitus.

Treatment of the middle ear by inflations alone, or by applications to the throat, and by inflations without nasal treatment is either useless or of far less value than naso-aural treatment. In the hypertrophic form of naso-aural catarrh, the treatment may be briefly defined as cleansing and astringent; while in the atrophic form it may be defined as cleansing and stimulant.

In the first class there may be placed the use of sprays of Dobell's solution in its weakest form, and solutions of iodide of zinc, and carbolate of zinc, not more than two and a half grains to the fluidounce in strength. To the fluidounce of water may be added two fluid-drachms of Listerine in the combination with sulphocarbolate of zinc. In the milder forms of nasal catarrh, an excellent spray may be found in equal parts of the distillate of witchhazel and water, and in children's hypertrophic catarrhs, the spray of fluid cosmoline (Petroleol) is most desirable as bland, alterative, and manageable, as it does not flow into the fauces and alarm the patient. In the denser, more chronic, hypertrophic state in the nares, the diseased tissues may be touched with the following preparation of iodine, conveyed to them on cotton by the cotton-holder, under perfect illumination of the nares by the forehead reflector:

℞.—Iodinii cryst. . . . gr. viij.
Potass. iodidi . . gr. xxxviij.
Glycerinæ . . . . f℥vj. —M.

In applying this to the inferior turbinated bones, great care should be taken to make the applications

Digitized by Google

to their upper surfaces, and not to touch their lower edges, nor the floor of the nares, as these parts are most sensitive. With these precautions the applications may be carried to the pharynx through the nares. Should smarting be brought about by these applications of iodine to the nares, it may be relieved by the aforesaid spray of fluid cosmoline. When this iodine solution loses its power to excite absorption, stronger iodine solutions may be used, as, for example, equal parts of tincture of iodine and glycerine. These applications shave down, so to speak, the hypertrophy. *No* form of nitrate of silver application is tolerated in the nares in the hypertrophic form of nasal catarrh.

The throat symptoms can be combated by suitable gargles or by direct applications of preparations of tannin or chloride of iron, made by the cotton-holder under illumination from the forehead mirror, directly to the diseased spots, and not by an indiscriminate swabbing, which is as injurious as it is unskilful. The day has gone by, thanks to special surgery of all forms, when diseased tissue is reached by all-embracing applications, which excoriate and cauterize healthy and unhealthy tissue alike.

After suitable applications are thus made to the nares and fauces, the tympana should be inflated. If the catheter is to be used, it is best done before applications are made to the nares, as saving just so much additional manipulation after local medication.

In the atrophic forms of naso-aural disease, the first consideration in treatment is the removal of the inspissated matters, crusts, scales etc., from the nares; this may be effected by the nasal douche, but I prefer other methods. On the whole the best results are obtained by softening sprays and subsequent removal of scales or crusts by proper forceps. After the parts are cleansed and exposed, the mucous membrane may be stimulated by nitrate of silver in powder[1] or in solution. The strength of the latter should never exceed 5 grains to f℥j of water. Preparations of sulphocarbolate of zinc and Listerine are also efficient as stimulants in these cases. The general rules to be observed in treatment of chronic naso-aural catarrh are: 1, in the hypertrophic forms, to allay engorgement, to soothe, at it were, the injected and inflamed parts; and 2, in the atrophic forms, to stimulate the mucous membrane of the nares and fauces. All of these methods must be conducted within reasonable limits.

Another important point is to bear in mind the naturally erectile nature of the tissues in the nares and nasopharynx, and their consequently easy excitability, and also that osmosis is easily effected in these parts.

Hence, in order to prevent this, a solution containing salt, for example, should not exceed 56 grains to the pint. If greater than this, exosmosis ensues and the tissues are drained too much; if less than this, endosmosis occurs, the tissues become distended, and pain and discomfort ensue. And this holds good for all saline solutions.

I have thus sketched very briefly the general plan of treatment in naso-aural catarrhs. When the nasal disease of either form demands more surgical treatment, such as the ablation of hypertrophy, the use of the galvanocautery, or the removal of diseased and necrotic bone, the affection has passed into the territory of the rhinologist.

It will be found, however, that while all chronic, aural catarrhs are associated with nasal catarrh, all cases of chronic rhinitis are not followed by chronic aural catarrh, and it will also be found that the worst cases of chronic rhinitis are usually not associated with aural maladies, and that the rhinitis of aural diseases is of a comparatively milder form than that found in nasal diseases alone.

A word of caution should be said here in relation to the use of the galvanocautery in the nose. It, like the nasal douche, is open to the criticism that, in some cases, it excites an inflammation in the middle ear. Very recently I have seen two cases of acute otitis media following the use of the galvanocautery in the nares for the relief of hypertrophic nasal catarrh. I know this is a small number of cases of inflammation attributable to the use of an instrument so frequently employed not only with benefit to the nares, but without simultaneous irritation to the ears, but in the cases I report I can see no other explanation of the aural inflammations except in irritation of the naso-pharynx, Eustachian tube, and tympanum, set up by the galvanocautery.

Conclusions.—1. That there is a constant causal relation between chronic nasal and chronic tympanic catarrh, in which throat and faucial diseases play only a subordinate part, and this naso-aural catarrh is found under two chief forms, viz., the hypertrophic and the atrophic.

2. It follows that, owing to this close connection between the nose and the middle ear, that treatment of chronic catarrh of the middle ear, to be efficient, must be coupled with that of the coexistent and causal rhinitis, and that treatment of the throat alone is of little avail in chronic aural diseases. Treatment of, and by the way of, the external ear is of course useless. It is also shown that tinnitus aurium from catarrhal causes is best overcome by treating the chronic rhinitis.

3. Since the appearances of the membrana tympani are so variable in the hypertrophic form, nothing can be predicated of the tympanic disease by simple inspection of the membrana. In the atrophic form of chronic aural catarrh, the appearances of the membrana being more consistent and invariable, the surgeon can predicate more of the tympanic disease from inspection of the membrane, viz., that it is sclerotic in form. From this variability in the appearances of the membrana in the hypertrophic form of aural catarrh, it follows that lesions of the membrana taken alone, are of little moment respecting the hearing. The lesions most competent to induce acoustic disturbances are apt to be situate upon the ossicula or upon the inner tympanic wall near the fenestræ.

4. It behooves the aural surgeon, therefore, to inspect and treat the non-surgical forms of nasal catarrh as they occur in chronic catarrh of the middle ear, laying more stress on the condition of the nares

[1] Dr. C. Seiler's formula: ¼–15 grain to 150 grains of powdered starch.

than upon the fauces, so far as any causal relations between these parts and the deafness are concerned.

THE ETIOLOGY OF TRAUMATIC TETANUS.[1]

BY P. S. CONNER, M.D.,
PROFESSOR OF ANATOMY AND CLINICAL SURGERY IN THE MEDICAL COLLEGE OF OHIO, ETC.

KNOWN from the earliest times, a wound complication of extreme gravity, the subject of many investigations and innumerable papers, traumatic tetanus is an affection respecting the cause and manner of the production of which there is still much uncertainty, and little, we might also say, no definite knowledge. There is therefore full justification for a brief consideration of the views that are held respecting its etiology; the more so as not only is there much advantage in knowing these respecting any disease, but, further, in this affection the adoption or rejection of certain methods of treatment is largely based upon the views entertained as to the cause of the muscular spasms.

The study of any considerable number of reported cases, in which the diagnosis has been correctly made, will quickly convince us that under the generic head are embraced two species, the one characterized by spasms primarily affecting the injured part, the other by those at first located in the muscles whose nerves have origin in the medulla oblongata. At least since the time of the appearance of Colles's paper (1852), there has been, as we believe properly, a disposition on the part of most to regard as cases of true tetanus only those of the last-mentioned kind. And yet, a death-producing generalization of spasms originally local, does, though rarely, take place, and the later stages of cases of this sort are identical with those in which the earlier symptoms were connected with the muscles about the jaws.

There is little or no question that the seat of the disease is in the central organs of the nervous system—scarcely more that it is essentially an exaltation of their reflex irritability: but how is this condition brought about? Is it by the nerves, or the blood-current; by extension of inflammation, by reflected irritation, by septic changes, or by the presence and development of microörganisms? Each of these theories, with the exception of the last, has had numerous advocates, and the arguments therefor have had apparently substantial basis in the symptoms present, the results of treatment, and the pathological conditions discovered upon autopsy. That it is by ascending neuritis that the morbid state of the cord is induced is thus indicated. There is beyond doubt nerve-injury in the original wound, such injury being either of incision, complete or partial, of contusion, of laceration, of puncture, or of compression or irritation from an unremoved foreign body. Resulting therefrom is inflammation of the nerve-cord, either involving its whole extent or macroscopically viewed, affecting parts here and there as it is traced upwards; at times attacking few fibres and discoverable only by careful microscopical examination: such inflammation being indicated by congestion, by exudation, by connective-tissue proliferation, by degeneration of the tubules. Passing to and up along the cord, there are to be found such conditions of the bloodvessels, the coverings, and the gray and white matter as are indicative of inflammation.

The chain would seem to be complete and the correctness of the theory established; but nerves are constantly being injured, yet tetanus is of rare occurrence. In very many cases it has been impossible to discover either neuritis or myelitis; and it seems much like begging the question to claim, as has been done, that in such cases there is pathological change, but of so delicate a nature as not to be discoverable by our present methods of investigation. In the quickly occurring and rapidly fatal cases, there is not time for the development and extension of inflammation. Inflammatory nerve changes have often been observed when there has been no tetanus; and the symptoms of acute ascending neuritis are altogether different. The spinal cord changes in certain cases are much more probably results than causes, due to circulatory states consequent upon the convulsions; in other cases they cannot be distinguished from those repeatedly found associated with diseases unattended by spasms. And, lastly, were an ascending myelitis the determining cause of the irritability, there ought to be observed a progressive involvement of the muscles upward from the level of the injured area which is not the case in true tetanus; or from the feet and legs, if it be true, as claimed (Michaud), that no matter where the wound is located, the most marked pathological changes are in the lower part of the cord.

Fifty years of experience have but confirmed the truth of Travers's declaration, that "The evidence to establish that tetanus has its origin in inflammation of nervous structures has failed."

If not of inflammatory origin, is tetanus a reflex neurosis consequent upon remote nerve irritation? Such is the opinion most generally entertained whether the disease be associated with a wound or occurring idiopathically. It is argued that, as every one knows, peripheral irritation will give rise to movements affecting, it may be, a whole extremity, movements independent of and in spite of the action of the will; that nerve injury and pressure are often associated with localized muscular cramps or jerkings; that the disease is most frequently developed in cases in which, from the character of the wound, the nerves of the part are torn, bruised, or crushed; that not seldom it is found that an irritating foreign body remains in the tissues, and the sharper, the rougher, the more irritating the substance, the greater the likelihood of the development of the affection; that the state of abnormal reflex excitability especially occurs when the wound is in a part in which sensitive nerve fibres are most numerous and of the highest functional value; that it is often so quickly developed that it could be so only through reflex irritation; lastly, that it can be experimentally produced by wounding nerves.

By reflex irritation may properly be explained the manner of the production of the spasms in those

[1] Read before the American Surgical Asssociation, Washington, April 24, 1885.

Digitized by Google

cases in which they originally affect the injured part and thence pass upward and outward ultimately to become general. Such progression is strictly in accordance with Pflüger's laws, and, were the cases presenting the phenomena of it other than exceptional ones, perhaps not to be justly considered as those of true tetanus, the theory of radiation from an irritated nerve centre might, without hesitation, be accepted as the correct one. But what is known respecting the physiology of the nervous system does not warrant us in believing that in a healthy individual a reflex irritation, starting, it may be, in the foot or the hand, passing over all the intervening portion of the cord will produce in its upper part an influence that will manifest itself not in a single or in a few eclamptic seizures, but in a persistent contraction of the muscles passing from above downward, sooner or later, in most cases, to become general. If nerve injury is the determining cause, why is the disease so infrequent, attacking but 1 in 200, 300, 500, 1000 of the surgical patients in large general hospitals or of the wounded of modern wars? Surely the assumed exciting cause is often enough present.

Consider for a moment some of the special nerve injuries which have been followed by tetanus. In a few cases examination of the wound has shown nerve fibres included in the loop of a ligature—similar inclusions of nerves of smaller and larger size must have occurred over and again. In how many of the declared cases of tetanus must be seen either spasms beginning in the neighborhood of the wound or a mere association of nerve-inclusion with true tetanus otherwise produced. Even if the freeing of the constricted nerve has put a stop to the morbid condition, in some of the cases at least, study of the reported symptoms will show that there were present only limb spasms; tetanoid, but no more the convulsions of true tetanus than are the stump twitchings which are so often met with.

Again, have hand, and especially foot wounds, that are unquestionably oftentimes followed by tetanus, such danger attached to them as is so generally believed; and if so, is it due to the fact that in these regions are terminal fibres of highly sensitive character correspondingly liable to become irritated? Although it would seem from published statistical tables (*e. g.*, that of our distinguished Fellow, Dr. Yandell), that hand and foot wounds furnish about fifty per cent. of the cases of tetanus that occur, before concluding that such tables establish the excessive danger of injury of these territories, errors of diagnosis must be eliminated and determination made of the number of these wounds in comparison with the whole number of traumatisms occurring. It is in this connection an interesting fact that in over 16,000 wounds of the foot in our late war there were but fifty-seven cases of tetanus, and in perhaps 12,000 or 13,000 of the hand but thirty-seven. Again, in punctures of both hand and foot, it has not been so much when they have affected the sensitive parts of the fingers and toes, but when there has been piercing of the palmar and planter fasciæ that tetanus has been most commonly developed.

If the pressure or more active irritation of a lodged foreign body is the exciting cause, why should it so seldom exert its deleterious influence; and why should the experimental injuries inflicted upon animals so generally fail? In only a very few cases, as those of McDowell and Brown-Séquard, has it been found possible to produce the tetanic state. The results of operative treatment certainly do not lead to the acceptance of the irritation theory. Amputation has seldom relieved, and is favored by few or none at the present day. Nerve section secured 10 favorable results out of 16 cases collected by Letievant, but in at least one-half of the patients who recovered, the muscles first affected were those of the injured parts; and, further, this operation has been performed in too small a number of cases for its statistics to have much argumentative weight. Nerve-stretching, according to Agnew's table, was followed by cure in one-fourth of the cases in which it was tried. But here again, the two classes of spasms have not been separated, and further, in most if not all the successful cases, "internal remedies were also administered." In one of the cases reported as cured by this operation, of which I have personal knowledge, twenty-four hours after the stretching, the spasms were still present in the opposite limb, and chloral and the bromides were steadily administered. It is an interesting fact to notice in this connection, that of the 350 nerve-stretchings for causes other than tetanus given in Agnew's tables, not a single one was followed by tetanus. If such exemption is not accidental, in it is to be seen additional evidence of the correctness of the irritation theory, or was it due to the absence or very limited amount of inflammation in and about the wound, and the great care taken to secure, if possible, primary union?

The two facts that speak most strongly in favor of this theory of reflex neurosis are the excessively quick development of the morbid state in certain cases, and the influence of cold, acting either alone or in conjunction with traumatism. It is certainly hard enough to understand how reflex irritation from a lacerated wound of the thumb could give rise to a tetanus that should kill the subject of it in fifteen minutes from the time of the injury, but much harder to explain the occurrence on any other theory. Unfortunately, Robison's case is very imperfectly reported, so that there is no way to determine whether or not the facts were as stated, and, still more, whether or not very material facts have not been omitted.

The influence of cold has long been believed to be a potent one in the production of tetanus; especially when the low temperature has been associated with much dampness; such influence being most likely to be manifested in regions or seasons in which there is a great difference between midday and midnight heat. Acting locally upon an exposed wound, or generally upon the body at large, it has been held that the cold damp air affects the terminal nerve-filaments, by reflex action arousing an abnormal irritability of the central organs. This may be so; and a like action may result from the high temperature of tropical countries, but as will be seen later, the produced effect may be in consequence of the presence of chemical or living irritants, the development of which is favored by the thermal conditions, aided it may be, when cold is acting, by

Digitized by Google

the internal congestions consequent upon the external chilling.

If neither through nerve-inflammation nor reflex action is developed that extreme irritability of the central organs that manifests itself in tetanic spasms, how then can it be induced? Only by changes in their blood-supply; changes either in quantity or quality. Experimentally, convulsions can be produced by overfilling or by emptying, by injection and by bleeding, but such convulsions are not tetanic. Both an hyperæmic and anæmic state of the cord have been repeatedly shown upon autopsy, but here, as always, when diametrically opposite conditions are found, neither can with good reason be regarded as primarily causative. It is not then in the quantity, but in the quality of the blood, that there is to be found what is sought, if the humoral theory be the correct one, in the presence of a septic element developed in the blood or of a special organism coming from without. Neither chemical examination, microscopical investigation, nor experimental injection has, up to the present time, established the truth of this theory,[1] which is rendered probable, if at all, only by reasoning and analogy. That certain vegetable alkaloids and animal poisons entering the circulation so affect the spinal cord and the medulla as to give rise to severe and rapidly recurring, oftentimes fatal convulsions is a fact. In the absence therefore of absolute proof to the contrary, it is not impossible that tetanus may be thus produced. In the wounds that are most likely to present this complication, there is, both in the fluids poured out and in the tissues disorganized, abundant material, by the decomposition of which septic matter may chemically be developed that under favorable circumstances of atmospheric conditions or constitutional state may produce tetanic spasms. Even in a physiological fluid—urine—Gautier was able to find a ptomaine capable of tetanizing animals. Does not the danger of punctured wounds of the fascia of the hand or foot lie in the pent-up fluids rather than in the nerve-damage; and is it not in the pus, the pieces of clothing, the bits of wood that have been found in some of the reported cases, and not in the lacerated nerve-fibres that one should look for the exciting cause of the fatal affection? The veins and lymphatics of the nerves themselves may readily be the channels through which the morbific matter may be carried in; and the anatomical fact that a direct relation exists between the sensibility of a nerve, and the number and closeness of connection of its associated lymphatics, may go far in explaining why tetanus is so frequently associated with slight wounds of parts endowed with high sensibility, as the fingers and toes.

The influence of climatic conditions and atmospheric states may find explanation in their power over decomposition and organic growth, or in the produced constitutional depression of the system, rendering it less resistant to the poison or the germ. Because of such depression we may, perhaps, understand why malaria or scurvy, or anxiety or grief have been found at times conditions precedent to the outbreak of tetanus. When no wound is present, it can only be assumed that it is in the natural secretions that the irritant is developed. The idiopathic cases of the disease are the ones the occurrence of which it is hardest to explain upon the humoral, indeed, upon any theory.

But, it is contended, that were the exciting cause chemical or organic, the disease toxæmic, its attacks should be associated with fever, which is not the case. Yet at times distinct prodromal malaise has been noticed, and exceptionally a marked elevation of temperature. Is fever a necessary result of the presence of poison in the blood, or an essential symptom of a mycosis? For answer, we have but to remember the symptoms of strychnia poisoning, of hydrophobia, and of cholera. Perhaps, as was suggested by Dr. Joseph Jones, in tetanus the frequent absence of high heat has its explanation in the correlated muscular motion that is present.

From time to time reports have been made of greatly disproportionate occurrence of the disease in a single ship of a squadron, building of a hospital, or even bed of a ward. How otherwise than by the presence and action of a virus or a germ can such be explained? That many wounded after a battle or long transport should be so attacked might with more or less truth be attributed to a generally acting atmospheric condition, but not any distinct localization, as it were endemic prevalence, of the affection.

Is it not, then, from very careful chemical and microscopical examination of the secretions of the wound, the tissues in and about it, and the blood of the part and the system at large, that we may hope to receive definite information respecting that which gives rise to this obscure affection? Will it prove to be a peculiar toxic material developing in the breaking down, dying and dead, material, or a specific organism, that will, so far as the cause is concerned, ally tetanus with anthrax, septicæmia, and erysipelas, an organism entering into the open wound, or carried in with the vulnerating body? Whatever it may prove to be, if it is discovered at all, we will hear no more of hypothetical "personal predispositions," or "parts of least resistance," and the treatment will be directed rather toward preventing the development of the poison, the entrance of the microorganism, or the sustaining and quieting the patient until such time as the one shall be eliminated, or the other have completed its life-history.

[1] L. Curtis, of Chicago, thought he had discovered in the blood a peculiar microörganism, but further investigation showed that it was equally present in the blood of a healthy mother and sister of the patient, and in the water of a pond near by.

Arloing and Tripier injected blood from a horse affected with tetanus into the jugular vein of a healthy one, but failed to produce the disease.

AN INTERESTING CASE ILLUSTRATING EMMET'S NEW OPERATION FOR RESTORATION OF PELVIC DIAPHRAGM.

BY J. M. BALDY, M.D.,
OF DANVILLE, PA.

MRS. G., a young German woman, twenty years of age, first child, protracted labor, attended by midwife, child died twenty-four hours after delivery. On

Digitized by Google

examination I found the perineum torn to the sphincter, with complete loss of muscular and fascial support in the pelvic diaphragm. There was a large mass of scar tissue over the sphincter, but the recto-vaginal septum above this point was thin, being composed merely of the two mucous membranes. There was a small rectocele with deep lateral sulci, the right being the deepest and longest. The cervix was split bilaterally, flush with the vaginal walls, the lips were everted and eroded, the fundus was retroverted, and the whole uterus low down. Pelvic pains and general reflex disturbances were very marked, incapacitating her for marital relations and domestic duties. So much so that she, on several occasions, left her husband and repeatedly expressed the desire to die.

Her general and local condition improved under treatment, but not to any marked extent. The local irritation and chronic engorgement called loudly for operative interference, to which she gladly submitted.

Both cervix and perineum were closed at the same sitting. The surfaces of the cervical tear were freshened with Dawson's tenaculum-pointed scissors by four clean cuts extending far back into the angles of the laceration, thereby removing a large mass of cicatricial tissue from each angle. The tear was then closed with shotted silk wormgut sutures, securing perfect apposition of the freshened surfaces.

I then closed the perineum according to Emmet's new inside operation for loss of muscular and fascial support of the pelvic diaphragm. The steps of the operation are simple. They consist in passing a ligature through the crest of the rectocele and a tenaculum into the labial tissue on each side directly opposite the lower caruncle. Bringing these three points together will form the triangles to be freshened, as is so fully described by Emmet in the third edition of his work. The triangles were then freshened with curved scissors by means of transverse strips or the "carpet rag" method of denudation. The scar tissue was removed completely to the rectal mucous membrane.

The operation differs from the old one principally in the introduction of the sutures, the denudation differing only in freshening the sulci far up to their apices, and in not freshening labial surface which has not been torn. The stitches were introduced from the apex of each sulcus, forward. A tenaculum was hooked in the apex of one sulcus, drawing the apex backward towards the cervix and thus preserving the line on which the sutures were to be introduced, intact. The first two sutures were passed transversely and were followed by others introduced *forward*, including plenty of tissue, towards the operator, to the bottom of the sulcus, where they were reintroduced and carried *backward*, emerging just beyond the freshened edge of the rectocele directly opposite the original point of introduction on the other side of the sulcus, and thus forming a V-shaped course. Six sutures were thus introduced in each sulcus. When these were drawn up into place and closed, there remained only a small triangular space of freshened surface in front of the rectocele, which was closed by Emmet's crown and two superficial, external stitches.

The crown stitch consists of passing a suture into labial tissue between points of original introduction of tenacula, including the crest of the rectocele. All sutures introduced were of shotted wormgut of the finest quality. In adopting this method of closure, perfect restoration of the perineum and the posterior vaginal wall, which is the natural support of the anterior wall and bladder, was secured.

The amount of discomfort afterward was slight. The knees were not bound together as in the old operation, no opiate was needed, there was no swelling or oozing and very little pain. The bowels were kept soluble and the patient passed her own urine after the first day. Vaginal injections of warm water and astringents were used and a small piece of carbolized gauze, spread with cosmoline, was introduced into the vagina daily. Union was perfect throughout. The external stitches were removed on the eighth day, and the woman was up and around enjoying good health by the fourteenth day.

MEDICAL PROGRESS.

THE HIGH SECTION WITH SUTURE OF THE BLADDER.—G. TILING, in the *St. Petersburger med. Wochenschrift*, 1885, No. 4, advocates, as the result of operative experience, the high section with suture of the bladder.

After the operation by median section the writer observed a prostatic abscess, followed by inflammation of the whole pelvic floor. The whole pelvic diaphragm became hard and rigid, without resulting suppuration. The condition persisted one year; at the end of the second year the symptom disappeared.

This disagreeable experience led the writer to resort, in his next four operations for the removal of large stone, to the high section of the bladder. In a boy, seven years of age, the operation was easily performed without dilatation. The peritoneum was not engaged, and the bladder wound was closed by five silk sutures, which did not involve the mucous membrane. The retained catheter was not required, and the wound united by first intention.

In the second case, a man aged twenty-two years, the extent of the bladder was so limited that the peritoneal fold lay beneath the symphysis pubis. The stone weighed 730 grains, necessitating an extensive vesical incision for its removal. In spite of temporary catheterization, the wound reopened on the sixth day, and eight weeks elapsed before the fistula healed. Two years later an abdominal hernia, half the size of an apple, in part containing the bladder, was developed.

In the third case—the patient was a man thirty-eight years old—the bladder, when full, extended to a point midway between the symphysis pubis and the umbilicus. The anterior wall was, nevertheless, covered by the peritoneum, which extended an inch below the symphysis. The sutures came away on the seventh day. The patient suffered great pain in the region of the right kidney, but was discharged much improved in two weeks, though a capillary fistule still persisted.

In a fourth patient, who from childhood had suffered from pain in the bladder, operation was successfully performed. The peritoneum was situated very high and the incision was closed by eleven interrupted silk sutures, and an additional continuous suture to support

Digitized by Google

the former. Union took place in two weeks with the application of a retained catheter.

Although the operation is favorably considered by Tiling, he fails to discuss its difficulties, especially the introduction of the suture, which must be applied in a very contracted space.

In a case elsewhere reported, a fistula, resulting from the operation, persisted, and all means taken to close it were futile, even permanent drainage of the bladder failing entirely.—*Centralblatt für Chirurgie*, June 6, 1885.

TRAUMATIC HERPES CONSECUTIVE TO SURGICAL OPERATIONS AND DENTAL AFFECTIONS.—DR. TH. DAVID summarizes the different forms of traumatic herpes consecutive to surgical operations and dental affections as follows:

1. There frequently occurs, more particularly in women and young subjects, as a result of operations upon the teeth or of affections of the dental apparatus, an herpetic eruption, either upon the gingival, buccal, or labial mucous membrane, or upon the skin of the face.

2. The eruption is either confluent or discrete.

3. It is sometimes accompanied by fever and sometimes exempt from all febrile manifestations.

In the first case it is a species of febrile herpes, or rather a local manifestation of herpetic fever (Parrot), a manifestation determined by a lesion of the dental apparatus.

In the second case it is an eruption originating in a nervous disorder, determined by operations or dental lesions, traction upon the buccal commissure, and by pressure upon the cutaneous and mucous nerves of the face.

4. This latter variety of traumatic herpes, when accompanied by fever, swelling of the face, redness of the skin, may simulate simple inflammation or erysipelas.

5. The affection is not of a serious nature, and disappears after a short duration.—*Journal de Médecine de Paris*, June 14, 1885.

THORACIC ATROPHY IN PLEURISY.—M. DESPLATS, at a recent meeting of the Société des Sciences Médicales, expressed the following opinions relative to pleuritic atrophy of the thorax:

1. Among pleuritics atrophy of the thorax is a frequent and early affection.

2. Such atrophy produces at an early date difficulty in respiration.

3. Later it causes, to a great extent, the deformed thorax, so frequently a result of this disease.

4. And this favors indirectly the deposit and increase of tubercular material.

It is, therefore, necessary—

(*a*) To prevent atrophy, when a predisposition to it exists.

(*b*) To arrest it when established.

(*c*) And, also, to combat it by active treatment, including general tonics and local stimulants, particularly faradization, respiratory gymnastics, and by the use of compressed air.—*Revue de Thérapeutique*, June 15, 1885.

INOCULATION OF TUBERCULOSIS IN THE HUMAN BEING.—E. A. TSCHERNING reports in the *Fortschritte der Medicin*, 1885, No. 3, the case of a young woman, 24 years of age, not scrofulous, who wounded herself on the volar side of the first phalanx of the middle finger, upon a cuspidor containing tubercular sputa rich in bacilli. Fourteen days later there were symptoms of a beginning panaritium. There was no suppuration, but a swelling the size of a pea made its appearance between the skin and sheath of the tendon.

This was enucleated and the wound rapidly healed. Several months later, on examination of the finger, it was found œdematous, and the sheath of the tendon swollen, rendering use of the member impossible. In addition, the cubital and axillary glands were swollen. Enucleation of these glands was deemed advisable, and the operation performed, while at the same time the middle finger was amputated at the metacarpo-phalangeal joint, and the diseased tendon, as well as the somewhat extensive granulation tissue, removed as far as the middle of the hand.

The sheath of the tendon was found by microscopic examination to be filled with abundant granulation tissue, in which were found numerous miliary tubercles, however with not constant central caseation, numerous large cells, and partly central giant cells.

In the lymphatic gland was also found miliary tubercle, which here, as well as in the tendon-sheath in all the sections, plainly exhibited the presence of tubercle bacilli, generally solitary, but occasionally in groups of two or three bacilli. The condition was perfectly in accord with that existing in surgical tuberculosis. Inoculation experiments unfortunately could not be carried out. Two months after the operation the patient was perfectly restored to health, and there were no indications of further lymphatic complication. Up to the present time the case is unique.—*Centralblatt für klin. Medicin*, June 20, 1885.

BILATERAL NEURALGIA AND DILATATION OF THE STOMACH.—MM. CHANTEMESSE and LE NOIR, in an elaborate paper based upon observations made in the clinical service of M. Bouchard, describe a form of bilateral neuralgia due to dilatation of the stomach. The writers consider the symtomatology of the disease as well established, though its differential diagnosis is frequently difficult.

This form of neuralgia is frequently ushered in by a prodromic period, during which, while there is little or no pain, digestive disturbances are more or less marked, but are not appreciated by the patient in whom they are marked by vertigo, pain or loss of sensibility in an arm of some portion of the member, in a finger, or, further, by a sense of constriction of the upper part of the thorax.

Examination will at this stage sometimes discover that for several years the patient has suffered from slowness of digestion and drowsiness after meals. Later on, pain appears as a symptom, at first mild, afterward more intense.

Gastric disturbance now increases, sometimes causing greater distress than the neuralgic symptoms, and examination reveals the existence of gastric dilatation, which is frequently very extensive. This condition is frequently followed by a chain of symptoms, embracing pain throughout the entire body, palpitation, vertigo, and semi-syncopal state, etc.

Digitized by Google

That the essential cause of the neuralgia is dilatation of the stomach is evident from:

1. Coexistence of the neuralgia with dilatation of the stomach.

2. The appearance, first, of gastric symptoms, neuralgic phenomena are secondary and are suddenly manifested when the gastric disturbance is exacerbated, and are diminished when this diminishes in intensity. Diagnosis is sometimes assisted by observing that acute neuralgia disappears concomitantly with a notable diminution in the volume of the stomach.

3. The failure of local treatment and beneficial result of means directed to the relief of the stomach.

The prognosis is serious, inasmuch as the presence of such neuralgia is an indication that the gastric disease has reached an advanced stage, and that its cure is difficult, even when the condition of the stomach is capable of great improvement.

Intensity of pain is not of the same prognostic value as is a knowledge of the length of time during which the symptoms have persisted. In acute forms of the disease, which accompany digestive disturbance, their intensity is great, nevertheless they may disappear entirely in a few days.

On the contrary, in the chronic form, the neuralgic symptoms, though slight, persist with great obstinacy.

The therapeutics of the disease is entirely confined to such remedies as are calculated to improve the condition of the stomach.—*Archives Générales de Medicine*, July, 1885.

RESECTION OF THE HUMERUS AT THE SHOULDER-JOINT.—MR. W. I. WHEELER, in *The Dublin Journal of Medicine*, June 1, 1885, reports three cases in which excision of the shoulder-joint was performed, the operation in every instance resulting happily with great improvement in the motions of the arm. His comments on the operation are as follows:

Excision of the shoulder-joint for disease is not so commonly performed as is excision of other articulations, for the simple reason that disease of the articular structures of this joint is not frequent, and when it does occur it often terminates in ankylosis. Again, it is not very uncommon to find that supposed disease of the shoulder-joint is merely caries of the coracoid or acromian process, and that the osseous structures forming the joint are unimpaired; consequently, the removal of such diseased parts will be sufficient; indeed small sequestra, even in the articulation, may be successfully removed without resecting this joint. But there are other causes, apart from disease, which may demand resection of the scapulo-humeral joint, such as gunshot wounds, old and painful as well as compound dislocations, tumors of the head of the bone not cancerous, compound and comminuted fracture of the articulation.

It makes, however, very little difference for what cause we may have to perform excision of this joint, so long as the treatment be adopted which will prove most beneficial to the patient, and which will endow the hand (to which the other joints of the upper extremity are secondary) with the widest range of usefulness.

With regard to the incisions for this operation several have been advocated—the T, the V, the inverted ⅂, as well as the longitudinal incision through the deltoid muscle, which, in his opinion, is the one calculated to afford the best results, and which is therefore the one he practises. There are several movements in the shoulder-joint—as rotation, abduction, elevation, adduction, and antero-posterior movements—and if the deltoid be cut across, the power of abduction and elevation must be lost, but if its fibres are merely divided the probability is that their movements may be retained with regard to the saving of the long tendon of the biceps. He strongly advocates that, when possible, this should be preserved. He is aware that in many cases of disease it is destroyed and good results have ensued, but he has seen more useful arms and more extensive motion follow when it has remained intact. He has not found it necessary to continue making the counter-openings for drainage. The position of the arm is undoubtedly away from the side and somewhat forward; this favors the contraction of the wound, and the bonds effecting repair are shorter.

EXTIRPATION OF THE GALL-BLADDER.—DR. THIRIAR, reports, in the *Bulletin de Academie de Méd. Belgique*, a case of extirpation of the gall-bladder in a patient who, for a long time previously, had suffered from hepatic colic, which resisted all treatment. No gall-stones were supposed to exist in the bladder, but, acting upon the theory that sooner or later calculi would be formed which, through their inability to escape by the common duct, would be the origin of intrahepatic calculi, he advised the removal of the viscus. The operation was performed as follows: the patient having been anæsthetized, an incision was made over the region of the gall-bladder, a short distance from the costal border, and about six inches in length. An incision almost three inches in length was then made transversely to the fibres of the external abdominal muscle, thus making a T-shaped wound. The abdominal cavity being thus reached, the adhesions found to exist between the colon and the liver were carefully broken up and the gall-bladder was found to be flaccid, of a red color, muscular, and with thickened walls. Very little bile was present in the organ and no concretions in the excretory duct. The gall-bladder was intimately adherent to the duodenum. These adhesions were broken up and likewise the organ was detached from the liver. When the cystic canal had been carefully isolated, a ligature of sublimated silk was thrown round its origin beyond its neck, and a second ligature was placed as a precautionary measure a little higher, after having removed the small quantity of bile which was in with it. Excision was now practised between the two ligatures. The lips of the cystic canal were united by fine sublimated silk sutures, and the wound was carefully disinfected by a solution of corrosive sublimate. The edges of the abdominal wound were united by peritoneal, deep, and superficial sutures of catgut. The operation was entirely successful, being followed neither by vomiting, pain, nor fever.

The third day the patient sat up in bed and in six days she was able to walk. Fourteen days she was entirely well.—*Journal de Médecine de Paris*, June 7, 1885.

REMOVAL OF THE OVARIES IN THE TREATMENT OF UTERINE FIBRO-MYOMATA AND PERSISTENT HEMORRHAGE.—DR. SIMON DUPLAY, in a memoir read before the Academie de Médecine de Paris, June 2, 1885, upon

Digitized by Google

the removal of the ovaries in the treatment of uterine fibro-myomata and persistent hemorrhage, reached the following conclusions:

1. The ablation of both ovaries is found to be exceedingly beneficial in the case of uncontrollable hemorrhage, symptomatic of the presence of fibrous tumors of the uterus.

2. Although the mortality incident upon the operation is not so great as to be serious, being not in excess of 14.6 per cent., nevertheless, it should not be resorted to until all other therapeutic measures have failed.

3. It is especially indicated in the case of fibro-myomata, great or small, in which hysterectomy is occasionally impossible and always exceedingly grave if not necessarily fatal.

4. In these conditions castration is almost constantly followed by complete cessation of the hemorrhage, and very frequently by a diminution in the volume of the tumor.

5. Castration is contraindicated in very large fibro-myomata and in cysto-fibromata, for which hysterectomy only is applicable.

6. Castration should always be double, and it is advantageous to remove at the same time both the ovary and the fimbriated portion of the Fallopian tubes. —*Archives Générale de Médecine*, July, 1885.

A NEW METHOD OF RELIEVING A COLD.—A writer in *El Siglo Medico* strongly recommends the following as a certain means of relieving the discomfort incident to cold: Pour about a half pint of boiling hot water over about a drachm of pulverized camphor, and inhale the vapors arising therefrom ten to twenty minutes.

Great relief is at once experienced, and after two or three repetitions the discomfort is said to disappear entirely.—*Gazzetta degli Ospitali*, June 21, 1885.

TREATMENT OF SUPPURATIVE MIDDLE OTITIS WITH PERFORATION.—E. GIANPETRO recommends the following treatment of suppuration of the middle ear with perforation of the drum:

℞.—Acid. carbol. cryst. . . . ℥ss.
Aquæ dest. . . . . f℥iij.—M.

S.—Keep in flask for external use. By appropriate tube, at every irrigation not less than a quart of the solution should be used, and its application should be made morning and evening. Immediately after the use of the douche, three or four drops of the following mixture should be dropped into the middle ear:

℞.—Glycerinæ, puræ,
Iodoformi . . . . . ãâ ℥ss.

After cure of the suppurating process, cicatrization of the tympanitic membrane should be promoted by painting the margin of the perforation with iodized glycerine, tincture of benzoin, or with the following mixture:

℞.—Ol. terebinthinæ . . . . ℥iv.
Iodoformi pulverat, . . . gr. xv.—M.

S.—Apply to the margin of the perforation with brush.

Should all effort to cause cicatrization be fruitless, resort should be made to the application of artificial tympanic membrane.—*Gazzetta degli Ospitali*, June 24, 1885.

EPITHELIOMA OF THE CLITORIS: ABLATION AND CURE.—At a meeting of the Société Obstétricale et Gynécologique de Paris, held June 11, 1885, DR. POLAILLON reported a case of epithelioma of the clitoris, in which ablation was performed and resulted in cure.

The patient was a woman, aged seventy years, who entered the hospital complaining of a tumor of the vulva. There was no history or trace of syphilis. The woman pretended to have not been aware of the presence of the tumor for more than three weeks, though she acknowledged that at least two months previously she noticed frequently a purulent fluid and sometimes a little blood, and at the same time experienced pain comparable to the prick of a needle. It is difficult to believe that the vulvar tumor had so rapid a growth. It is probable that it was preceded by a wart or induration which for a long time remained stationary and suddenly took on a rapid growth. The woman was, however, negligent of her person, and her memory seemed much enfeebled.

The tumor occupied the clitoris and the left small lip. It was as large as a hen's egg, mammillated, livid, firm, and excoriated in points. The vulvar secretions, mingled with blood, along with the urine and epithelial débris, moistened its surface and gave rise to a disagreeable odor. The tumor was attached to the pubis at a level with the body of the clitoris, and hung down before the vulvar orifice. The meatus was not involved, and the mucous membrane of the vaginal orifice was normal. The labia majora did not present any suspicious induration, and no involvement of the inguinal glands was evident.

The general health of the patient was good. The tumor continually increased in size, while the pain increased in severity, and operation was decided upon.

After chloroformization, the base of the tumor was cut entirely round by the thermocautery, so as to exceed the limits of the diseased tissue. It was then gradually dissected out with the instrument at a dark-red heat. In spite of such precaution, bleeding was profuse, especially at the base of the clitoris, and five ligatures were required. The tissue removed embraced the whole body of the clitoris, the right lip, the superior portion of the left small and a part of the greater right lip. With a view of restraining hemorrhage by acupressure, three metallic sutures were introduced transversely at the upper portion of the labia majora. A rubber catheter was used in the bladder, and compresses saturated with boracic acid were applied. In three days the catheter was removed, and the fifth day the sutures were removed, hemorrhage being no longer feared. Several times daily the wound was cleansed with the boracic solution. The sixth day, abundant hemorrhage occurred, necessitating the use of an artery *pince*. Cicatrization proceeded gradually, and though the wound was not entirely healed the woman returned home eighteen days after the operation.

Though the patient has never since been seen, M. Polaillon entertains but little hope that the relief afforded will be permanent. In his opinion, epithelioma of the vulva, though rarer than that of the mouth, has the same tendency to recur, and in two cases operated upon, he has observed the return of the disease after a few months, and a similar result seems likely in the third case.—*Archives de Tocologie*, July, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL
OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JULY 25, 1885.

CHOLERA PROSPECTS.

THE cholera continues epidemic in Spain, but the press despatches do not indicate its spread in other countries, although it probably exists in the south of France, and any day may bring the news that it has again appeared in Paris. As yet, there are no indications that it has invaded Germany, or that it has appeared in any of the regions from which the main stream of emigration comes to this country, and there is, therefore, good reason to hope that we shall escape a visitation from it this year, or that, at worst, it will only appear at some of our maritime quarantine stations.

The course of the present epidemic in Europe has been exceptional as compared with former outbreaks. For more than a year it has lingered on the shores of the Mediterranean and in the Spanish Peninsula, the furthest point north reached by it having been Paris, where its effects were comparatively small. It does not appear, however, that the disease is any less virulent in type, or that the mortality among those attacked is any smaller than has been the case in previous epidemics, and the meteorological conditions of both the past and the present summer present no peculiarities which would explain the comparative limitation of the disease and its slow spread. All the circumstances seem to indicate that the warning which the nations of Europe received two years ago as to the approach of this disease, and the measures of sanitation which were taken in consequence, have had a good effect.

Of these measures, probably the most important have been those relating to water supply, and those resulting from the general diffusion among the people of the idea that the disease is usually communicated by articles of food or drink, and that, when only such articles are used as have been recently subjected to heat, the danger is small. If to this be added precautions as to disinfection of excreta, and the prompt boiling or destroying of soiled clothing or bedding, which might possibly contain the germs of the disease, there is no doubt that its spread may be greatly hindered, if not entirely stopped. The so-called preventive inoculation of Ferrán appears to have little or no effect as thus far practised.

The work of removing collections of filth, doing away with suspicious sources of water supply, such as wells in large cities, etc., has been greatly stimulated both in England and in this country by the threatened danger, and we probably have yet nine months of grace left for work in this direction, which should be vigorously pushed.

CARCINOMATOUS PYLORUS.

IN THE MEDICAL NEWS for April 11, 1883, attention was called to the different operations that had been practised up to that date for carcinomatous stenosis of the pylorus, and certain conclusions were reached as to the justifiability of the operations and their comparative value. It was then shown that of 60 examples of pylorectomy for carcinoma, 75 per cent. succumbed as the direct result of the procedure; 72.72 per cent. of the survivors suffered from a return of the disease; 27.27 per cent. remained free from recurrence for less than one year; and that not a single patient was permanently cured, or remained well for three years. Of 11 gastro-enterostomies, 72.72 per cent. died, while 3, or 27.27 per cent., survived, but of these 1 succumbed in five months, and 2 were alive at the end, respectively, of two and four months From these data the opinion was expressed that surgical interference in carcinoma of the pylorus should not be countenanced.

We have been led to lay the above summary before our readers in order that they may be enabled to compare the results obtained by surgeons generally with those furnished by VON HACKER from the practice of Billroth, and recorded in the *Beilage Zum Centralblat für Chirurgie*, No. 24, 1885. As is well known, the distinguished surgeon of Vienna has had a far larger experience with gastric surgery than any other individual operator; and although Péan and Rydygier had anticipated him in excising the pylorus, to him must be awarded the credit, if it be a credit, of pushing the operation into prominence. Hence, his experience must be full of interest for the practical surgeon, and particularly for those who intend pursuing their experiments in this field.

Digitized by Google

For carcinoma, typical circular resection of the pylorus was resorted to 14 times, with 6 recoveries, and 8 deaths, or a mortality of 57.14 per cent. Of the survivors, 3 died subsequently of recurrence at the expiration, respectively, of four, ten, and twelve months, 1 was living with recurrence, at the end of six months, 1 was living with recurrence in the glands of the groin twenty-one months after the extirpation of a nodule from the abdominal wall, her prolongation of life being four years, while the sixth was alive and well twenty-one months after operation. Hence, these cases show a direct mortality of 57.14 per cent., recurrence in 88.88 per cent. of the survivors, and not a single permanent cure.

Of the gastroenterostomies for carcinoma, 5, or 62.5 per cent., died, and in 3 life was prolonged for several months.

From these data it appears that the mortality of pylorectomy and gastroenterostomy in the hands of Billroth has been less than in the practice of surgeons generally, and that his final results have been as bad as those of other operators. In view of these facts, we still adhere to the opinion that we have expressed on several previous occasions, namely, that surgical interference is unwarrantable in carcinoma of the pylorus.

WHY THE NEW ORGANIZATION OF THE CONGRESS SHOULD BE REPUDIATED.

THE action of a large number of the most prominent medical men of this country, in declining official positions in the American Medical Association Congress, is due in part to disapproval of the rules adopted by its managers, and in part to the fact that these managers are not men who should be endorsed to the world as the leaders of the medical profession of the United States.

In secular politics we are familiar with the spectacle of fairly good platforms, with ring candidates thereon, and occasionally we see bad platforms, with fairly good men endorsing them; but here we have such a combination of bad platform and bad leaders that it is difficult to see how any one can support or work under them.

For the platform the New Orleans Meeting of the Association is mainly responsible; for, although it gave no formal instructions to the Committee, it indicated its wish that the Congress should be put on the same basis as the Association itself; while for the selection of the men to organize the Congress the Committee is alone responsible.

It is true that the New Orleans meeting by no means represented the Association, and was specially packed with delegates from two or three neighboring States, whose chief purpose in being present appeared to be to obtain control of the Congress; so that if a majority of the members of the Association express their emphatic disapproval of the action taken, which we have every reason to believe they entertain, this action will appear before the world in its true light, as the work of a comparatively small faction intensely desirous of office, and not as that of the Association as a whole. It is important, therefore, that this disapproval should be manifest and distinct.

No doubt it is a disagreeable duty to make public the mistakes and shortcomings of members of the profession; it is much easier to keep silent, and it is on this unwillingness of the best men to engage in anything like public controversy that the ring politicians rely. This time, however, they have gone too far, and their condemnation is well-nigh universal.

AN IMPORTANT SOURCE OF PROFESSIONAL HAPPINESS.

WHILE perfect happiness may not be the lot of mortals, probably physicians have as much enjoyment as any similar body of learned and useful gentlemen. Apart from professional study and work faithfully done, there are for the doctor, peculiar sources of happiness—wayside flowers which bloom only by his path. One of these sources is in his correspondence, and as this correspondence differs in subjects, so there are varying degrees of happiness which it gives him.

His morning mail, we will suppose, brings him four letters. The first is from the Universal Utopian Life Insurance Company, and encloses a blank containing various questions as to the professional standing and ability of Dr. A——; as to whether he is expert in physical diagnosis, as to his sight and hearing and as to his moral standing—nothing as yet in the form as to the color of eyes and hair, his complexion, and religious and political proclivities; "your answer will be strictly confidential." Not having seen Dr. A—— for many years, and possibly having only the slightest acquaintance with him, one is often sorely tried to answer the questions so that no injustice may be done either to the economical company which in part trusts you to select its examiners, or, it may be, to a most worthy member of the profession, and it is in the effort, and in the accomplishment of this high end that happiness is secured.

The second letter is from a very clever doctor who wishes you to recommend him for an office; he is weary of professional life, and burns with the noble desire to serve his country at Washington, or in a foreign consulship. How delightful it is to assist him in his lofty ambition, especially when he requests you to append your signature to the letter of recommendation, a statement of such titles as you may have, thereby impressing with your consequence the powers that be, who otherwise probably do not know

Digitized by Google

you from any other son of Adam. The mere accidents or adventitious circumstances of your life are thus used to help him. Of course, it delights one to comply fully with the instructions.

The third letter is from a doctor who desires you to diagnose a case of which he gives you a meagre history, often confused by non-essential opinions and facts, and also to suggest a plan of treatment. With the patient before him and ample opportunity for thorough examination he has failed, but depreciates his own ability, and exalts yours in supposing that you will succeed without such opportunity. The compliment thus paid is very high and is received with great gratitude. In your earnest study of the case as presented by letter, the mind is quickened, knowledge revived or sought, feelings of benevolence and kindness excited—a sincere desire to help your professional brother and a suffering fellow being exercised—and hence an unfailing joy.

But the fourth letter lifts you to the highest altitude of happiness. It comes from a reputable member of the profession who believes that all professional truth is to be reached by arithmetic; statistics are the alpha and omega of his life; only have enough figures properly arranged—columns broad enough and long enough—and the human race will be lifted to dwell forever in the clear and serene light of perfect knowledge.

Undoubtedly statistics have their value in medicine, but they must include only essential facts; they must relate to cases the conditions of which are like, they must be furnished by competent observers, and their accuracy secured by an actual record of observations made at the time of the occurrence of the cases, not trusted to uncertain memory; finally, they must be used, when collected, for the acquisition of truth, not for the establishment of a preconceived theory. How often, however, does the series of questions which the seeker for statistics presents you show that he is endeavoring to sustain a particular plan of treatment, instead of being, for the time, an intelligent, just, and unbiased judge; or else it contains interrogatories, some pertinent, some impertinent, hypotheses probable and improbable, possible and impossible, consistent and inconsistent. Dr. A——, for example, is preparing to read a paper upon diarrhœa before a local, State, or national organization, and his questions run possibly somewhat thus: How many cases of diarrhœa have you seen in your ten, twenty, or forty years professional life? Was heredity a factor in the production of the disease? If your answer is negative, do you not believe it might be in some cases? Do you believe microbes are the essential cause of the disease? If green apples were the exciting cause, specify the number, kind, and size of the apples; if the disease was attributed to "teething," please state the particular teeth concerned. What were the thermometric, barometric, and ozonic observations made when the disease was most prevalent? Do you believe that the induction of premature labor is advisable in some cases of obstinate diarrhœa? If premature labor be induced, would you use two ligatures or one for the cord? Please give the hygienic and therapeutic means which you have found most successful in the treatment of diarrhœa. Have you ever used germicides in the treatment?

Other questions of equal pertinence and importance are presented, and to answer fully all requires a large amount of patience and prolixity, and some pages of manuscript. But patience, prolixity, and pages are cheerfully given in the desire to gratify, it may be, a most worthy member of the profession, and to promote medical progress, while the proud consciousness of having done this affords unspeakable pleasure.

THE PALL MALL GAZETTE'S EXPOSURE.

THE recent exposure by the *Pall Mall Gazette* of a form of horrid licentiousness frequent in London has startled the world. That female virtue should be made merchandise, be bought and sold like the commodities of life in the world's great metropolis, does not speak well for the progress of the race or for the power of Christianity. Paganism in its worst estate could hardly be worse. In our own country when some licentious wretch, maddened by more than brutal instinct, rapes maiden or matron, it is not unusual for the swift vengeance of a mob to inflict death, in some cases preceded by cruel tortures, upon the criminal. But in London we have a similar crime annually committed upon hundreds and even thousands of young girls whose poverty and friendlessness have rendered them comparatively helpless, or who are blindly lured to their ruin—if need be, their very cries of remonstrance stifled, and resistance overcome by force—and English law seems utterly powerless to avenge their wrongs, or secure to others adequate protection. Beer and Britainism, according to Sidney Smith, are inseparable ideas. Licentiousness and London will also become as inseparable if the condition of things made known by the *Gazette* continues.

"The gods are forever just," exclaims Carlyle in his life of John Sterling. Would that this gruff immortal were still in the world to pour upon the perpetrators of these black crimes his fierce invective, and rouse the English nation to demand of their rulers suitable protection for the daughters of the people.

The revelations made by the *Gazette* affect medical men. One of the villainous debauchees who was a liberal purchaser of these unfortunate girls, consigning "to fate worse than death" hundreds of them,

Digitized by Google

is said to be a doctor. The certificates of virginity which were necessary to secure the sale of the unhappy victims of cruel lust, were given by physicians after examination. That medical men should descend so low as to be the paid panderers to shameless licentiousness, is surely a matter of reproach to the profession. London physicians of repute owe it to themselves, to the profession at large, to society, and to the world to discover, to expose, and to banish forever from their association those who have thus contributed to this damnable traffic.

We do not doubt that good will come from the exposure made by the *Pall Mall Gazette*. The electric light is a powerful aid to morality, and so when the light of knowledge shines in upon London's habitation of cruelty, and nefarious practices are thus publicly known, the intended victim will be warned and made wary, the criminals deterred in some degree, and the crime become less frequent.

Moreover, a purer, healthier public sentiment will be created, a sentiment that will serve the enactment and enforcement of just laws for the protection of female virture, and that will visit with condign punishment, social or legal, if not both, those who sacrifice virgin purity for the momentary gratification of sexual passion.

REVIEWS.

TOPOGRAPHICAL ANATOMY OF THE BRAIN. By J. C. DALTON, M.D., Professor Emeritus in the College of Physicians and Surgeons, New York. 4to. pp. 175. Pl. xlviii. Philadelphia: Lea Bros. & Co., 1885.

When one has a specially dainty morsel he is apt to reserve it to whet a declining appetite. So on our table has lain for some time this exquisite monograph of Dr. Dalton's on the Brain. We have just spent the first of many delightful hours in studying anew the anatomy of this forbidding yet ever alluring organ.

When Dean, in 1863, published his photo-lithographs of the medulla oblongata, they were a great advance on any previous attempts at exact reproduction of sections of the nerve-centres. But twenty years have seen great improvements in our means of embedding and section-cutting and in the heliotype process for reproducing photographs. The result is, such a series of plates that enable us to study, at leisure and with exactness, the details of structure of the brain seemingly impossible of reproduction, and, in fact, we believe abandoned as hopeless even by the Smithsonian.

The author has given us three series of plates, first, of the various surfaces of the brain, with three sagittal sections of one hemisphere; secondly, horizontal sections; and thirdly, vertical transverse sections—each of the last two at five millimetres' interval. We only regret that a few more plates have not been added, showing systematic sagittal sections of one-half of the brain at five millimetres apart, to complete the series.

The first plate, in its relief, is a wonderful fac-simile of the brain. As in each of the others, it is faced by an outline explanation-plate in addition to the text, which facilitates its study. The delicacy of tinting is shown by nearly all of the others, but especially by those showing faint outlines of the various gray nuclei and the gray substance of the cerebellum.

No one can study the brain accurately without this work, and especially no teacher should fail to possess a copy. It inaugurates almost a new era in anatomical text-books on this subject. As a specimen of book-making it is exquisite. We are both glad and sorry to learn that the moderate edition is already very nearly exhausted.

SOCIETY PROCEEDINGS.

AMERICAN OTOLOGICAL SOCIETY.

Eighteenth Annual Meeting, held at New London, Conn. July 14, 1885.

(Specially reported for THE MEDICAL NEWS.)

THE Eighteenth Annual Meeting of the American Otological Society was held at the Pequot House, New London, Conn., on Tuesday, July 14, 1885, beginning at 10 A.M., THE PRESIDENT, DR. CHARLES H. BURNETT, of Philadelphia, in the Chair.

Twenty-seven active members and one honorary member were in attendance.

THE PRESIDENT announced the decease of two members, Dr. John H. Dix, of Boston, Mass., who had been a member since 1868, and Dr. E. T. Ely, of New York, who had been admitted to the Society in 1880.

DR. S. SEXTON, of New York, presented a paper on

INFLAMMATION OF THE ATTIC OF THE TYMPANUM.

He considered the disease under two headings, acute and chronic inflammations of the attic. The latter form, presenting itself as deep sinuses, containing polypoid tissue, crusts, pultaceous matter, etc., leading from the inner end of the canal up into the attic, into the antrum, and sometimes through the membrana flaccida, is often the result of acute inflammation in early life. A minute anatomical description of the atticus tympanicus was given.

Acute inflammation of the attic may follow catarrh of the head, the exanthemata, the entrance of fluids propelled along the Eustachian tube in bathing or from the use of the nasal douche. The frequent occurrence of inflammation of the attic from these causes is readily accounted for, when we remember that the Eustachian tube at its tympanic orifice opens by a free sweep into the attic as well as into the antrum. Irritating fluids seem to be better borne in the lower than in the upper part of the tympanum. Inflammations of the attic may be simultaneous with, consecutive to, or independent of, the inflammation of the antrum. It is the more serious from the fact that swelling of the mucous membrane clogs the outlets and prevents drainage. In such cases the membrana flaccida is red, the vascular turgescence extending above into the external auditory canal, and sometimes downward along the short process of the malleus. The inflammation may extend beneath the margo tympanicus of the auditory plate, followed by effusion of serum and blood, pressing away the membrana flaccida and integument of the canal, producing

Digitized by Google

a bulging sac, so great sometimes as to conceal entirely from view the membrana tympani, and may even entirely fill the canal, and present at the lumen as a purplish tumor. In some cases rupture of some bloodvessels of the tympanic plexus takes place, producing sudden extravasation.

Periostitis of surrounding parts may occur and extend along the surfaces of the canal, the mastoid or squamous portion of the temporal bone. In nearly all cases inflammation extends into the antrum and mastoid cells, or those overlying the external auditory canal or in the tegmen. If the escape of secretions into the antrum or the Eustachian tube is prevented, the case is more severe, and extension to the cranial cavity more to be feared. Inflammation of the antrum often persists after the tympanum has healed, drainage taking place through the Eustachian tube or by a sinus through the cortex of the mastoid.

For treatment, Dr. Sexton relies upon drainage and the employment of such constitutional remedies as tend to check the inflammation and prevent the formation of pus, as mercury and calx sulphurata, etc. Owing to the difficulty of making an accurate differential diagnosis between the pains of pachymeningitis and neuralgic pains of otitis media, the surgeon should be very cautious about trephining the mastoid, when pain is the only indication. If pachymeningitis has appeared, it is evidently useless to trephine.

DR. D. B. ST. JOHN ROOSA, of New York, said that the remedies mentioned are not in common use in the way he recommends them. He has used mercury in doses of $\frac{1}{10}$ to $\frac{1}{8}$ grain, and also sulphide of calcium, but without any favorable effect. He considers a warm room, a good nurse, taking care of the bowels, and local measures, as the most important, while the external treatment may be of an expectant nature. He asked Dr. Sexton to describe a case, indicating the manner in which he would use these remedies.

DR. SEXTON answered that he gives the remedies in small doses, but frequently repeated. The moment there are symptoms of purulency, he uses the calcium sulphide, which, he believes, controls the process. It has been used by Ringer and Otis in suppurative affections in other parts of the body. Under its use, Dr. Sexton has seen congestion and swelling over the mastoid disappear.

DR. J. A. ANDREWS, of New York, showed an illustration of a case in which the inflammation was most intense in the upper part of the tympanic cavity, and a perforation was established between the mastoid antrum and the external auditory canal. The latter was very much swollen, and showed a fluctuating in the superior portion, which he incised, liberating a considerable quantity of blood and pus. A good recovery was made. Two months later almost the entire canal was occluded by a membrane, which has since disappeared without operative treatment.

DR. POMEROY asked Dr. Sexton whether he believed the administration of mercury in these cases relieves pain when there is pain, and, if so, what is the theory of its action.

DR. SEXTON replied that he had never used it exclusively for that purpose, neither did he recommend it for this purpose. He would rather employ aconite or pulsatilla, especially the latter. He also feels certain that the sulphide of calcium, when given alone, would relieve pain.

DR. AGNEW thought that when there is acute otitis media it is desirable to cut it short as soon as possible. In a case of beginning otitis media, he would give fifteen grains of calomel and a Turkish bath, if accessible. He asked Dr. Sexton what his treatment would be in a case of acute otitis media catarrhalis in an infant six months old.

DR. SEXTON said he would ascertain the general condition, with regard to catarrhal trouble, dentition, previous attacks of inflammation of the ear, etc. If there were an accumulation, he would not hesitate to let it out. But in the majority of cases at this age rupture has already occurred when the patient comes under observation. If there were suppuration, he would give calcium sulphide; if simple catarrh, he would give mercury.

DR. C. J. KIPP remarked that nothing had been said of inflation which will relieve the pain of the middle ear. When there is protrusion of the membrana tympani, incision will give relief to the suffering.

DR. S. THEOBALD had used the solution of atropia, 4 grs. to the ounce, and in combination with the internal administration of cathartics, with great benefit. He also spoke very highly of 15 grain doses of pyrophosphate of soda.

DR. C. J. BLAKE, of Boston, spoke of the important role played by the reduplication of the mucous membrane in the upper portion of the tympanum, which he has found in 15 or 20 per cent. of 200 cases examined, and which may tend to retain secretions. In some cases of acute congestion of the upper portion of the tympanic cavity he has observed a history of over-strain and nervous exhaustion, suggestive of the acute pneumonia found with precedent history of nerve-exhaustion. In these cases an incision along the line of the posterior fold is followed by improvement in the symptoms.

DR. SEXTON said, in conclusion, that from his experience during the last ten years he would give up local applications rather than the internal remedies he has recommended in his paper.

DR. W. W. SEELY, of Cincinnati, read a paper on

THE TREATMENT OF CHRONIC OTITIS MEDIA.

He felt constrained to condemn the slurring of some cases of chronic otitis media catarrhalis by specialists in various ways, as by putting the catheter of the balloon in the hands of the patients. He claimed that this class of cases is always amenable to treatment, and that only time and patience are necessary to manage them.

He believed the attention of the general profession is becoming too much centred on the Eustachian catheter as the only means of opening the tubes. Often catheterizing does more harm than good; and some application of boric acid and vaseline, or, still better, of yellow oxide of mercury, will open the tubes when the catheter has little or no effect. He said that salves have almost, if not quite, supplanted all other applications for nasal and naso-pharyngeal troubles.

He concluded his remarks with the following:

1. That only experience of sufficient length of time (often lasting over months) in each case can determine whether treatment shall be continuous (daily) or interrupted—*i. e.*, perhaps daily for a week, followed by an interruption of some weeks or months.

Digitized by Google

2. Only experience in each case can inform us whether treatment is to be entirely directed to the middle ear or entirely to the nasopharynx, or combined against both.

3. Only experience in each case can inform us whether injections into the tympanic cavity are called for. Under this head it was stated that direct medication either of the middle ear or nasopharynx, as routine treatment, is unwise, till simple inflation has failed.

4. Mechanical dilatation of the tubes is rarely necessary or advisable. Only in extremely dry states of the tube is dilatation followed by much good success.

5. Hearing tests are not reliable, and hence patients with great deafness, great loss of bone-conduction, etc., should not be sent away till the test by trial has been gone through with.

6. Simple inflation failing, the greatest attention should be given to the nasopharynx, even though it be in an apparently fair condition.

7. Syringing, douching, and swabbing the nasopharynx should be abandoned.

DR. CHARLES H. BURNETT, of Philadelphia, read a paper on

THE RELATIONS BETWEEN CHRONIC CATARRHAL OTITIS MEDIA AND CHRONIC RHINITIS.

(See page 57.)

DR. C. R. AGNEW, in the discussion on these two papers, remarked that he thought there was an anatomical objection to the use of salves, and that it was impossible to apply them to the whole of the diseased surface. He has used the nasal syringe for twenty years, and is not prepared to accept the law that it should be abandoned. He is more willing to agree with Dr. Burnett, but believes that more stress should have been laid upon the most important part of the treatment, *i. e.*, the hygienic part.

DR. ST. JOHN ROOSA thought, with the last speaker, that the principal and the only benefit to be obtained in the majority of these cases is by proper hygiene. He does not believe it necessary to continue our examination very long, or repeat them very often, to determine whether or not we may expect to give the patient any relief. If he finds diminished bone-conduction, he thinks it is unnecessary to go on treating the patient.

DR. E. WILLIAMS, of Cincinnati, had been in the habit of freely using the Eustachian catheter, and frequently introduces with great benefit to the patient a flexible bougie through the catheter.

DR. H. KNAPP said that when lately suffering from a catarrhal affection, causing sometimes considerable annoyance, he had employed, with considerable advantage, a salve of iodoform and vaseline.

DR. SEELY had adopted the use of salves as a routine treatment, and has had more satisfaction than by any other treatment. They remain longer in contact with the affected parts than solutions, thus giving a more decided effect.

AFTERNOON SESSION.

DR. S. SEXTON presented a *Conversational Tube* for the aural instruction of deaf-mutes. By means of this tube the pupil will hear his own voice and compare it with the voice of the teacher.

INSTRUCTION OF DEAF-MUTES.

PROF. A. GRAHAM BELL, Honorary Member of the Society, called the attention of the members to the large number of children who were classed in institutions as deaf-mutes, but who, under proper treatment and education, could be made simply hard-of-hearing members of society. He also referred to the importance of otologists' formulating a list of causes of deafness, to which principals of institutions might refer for the proper legislation in institutions for deaf-mutes, while as now the legislation only gives the causes as obtained from parents or friends.

DR. CHARLES J. KIPP, of Newark, N. J., reported

A CASE OF FATAL EAR DISEASE, BEGINNING AS A CIRCUMSCRIBED INFLAMMATION OF THE EXTERNAL AUDITORY CANAL.

The patient was a married woman, twenty-three years old. She was first seen nine months before her death. Since previous confinement, occurring four months before she came under observation, she had suffered occasionally with severe pains in and about the left ear. There were swelling and redness of the posterior upper wall of the external canal. No perforation and no otorrhœa. Under the use of leeches, instillations of morphia, and inflation of the middle ear, there was decided improvement when she passed from under observation. Eight or nine months later the pain again appeared shortly after confinement, which was found to be due to furunculosis of the external meatus. There was no evidence of disease of the tympanum or the middle ear. An incision was, however, made in the membrana tympani, but nothing escaped. The swelling of the meatus soon subsided, but the patient continued to complain of severe headache. The pain, however, was not in the mastoid region, nor was there any tenderness on pressure. She gradually failed and soon died.

At the autopsy there was found evidence of intense inflammation over the entire extent of the arachnoid and pia mater. There was a collection of pus immediately over the posterior surface of the petrous portion of the temporal bone. Pus was also found on the pons Varolii. A small abscess was found in the anterior part of the left lobe of the cerebellum, near its junction with the pons. The mastoid cells were filled with pus, and only a thin exudation was found in the middle ear.

DR. BURNETT reported a case similar in many respects, in which the patient died from what was diagnosed as cerebral abscess. No autopsy could be obtained.

DR. E. E. HOLT, of Portland, Maine, reported on the present condition of the patient from whom the

TERATOID TUMORS

were removed. This case was fully reported at the meeting two years ago. For one year the patient remained free of the disease, when it reappeared, and since has progressed rapidly.

DR. CHARLES H. BURNETT presented a paper on

THE LOCAL USE OF COCAINE AND BRUCINE IN DISEASES OF THE EAR.

He had tried both the sulphate and the hydrochlorate of cocaine in painful affections of the ear to produce anæsthesia. He finds neither efficient when the pain is

Digitized by Google

due to inflammation in dense tissues of the external auditory canal, as in furuncles of this part, nor when acute inflammation occurs in chronically thickened periosteal and mucous tissues in the tympanic cavity. The hydrochlorate of cocaine, however, is efficient to induce local anæsthesia in 4 per cent. solution, in cases of not excessive congestion of the skin of the fundus of the auditory canal and in the membrana flaccida of the drum-membrane, as is observed in acute coryza, and attended by pain of a not continuous nor intense variety.

The solution may be applied to the inflamed tissues either by mopping it gently upon the affected portion or by soaking a small dossil of cotton and laying it upon the seat of inflammation, both procedures being done under perfect illumination of the fundus of the auditory canal, by means of the forehead mirror. But solutions of cocaine are not competent to produce local anæsthesia in the external auditory canal profound enough to permit painless incisions into it. Local anæsthesia in the membrana tympani preparatory to paracentesis is not required, as the operation is not painful enough to demand local anæsthesia.

With regard to brucine, Dr. Burnett thinks that either in solutions of the alkaloid or of its nitrate or sulphate it has a useful future in the treatment of pain in the ear due to inflammation of the skin in the meatus and auditory canal, and in acute inflammations in chronically inflamed periosteal and mucous tissues of the fundus of the canal and the tympanic cavity.

DR. E. E. HOLT, presented a paper entitled

DOES COCAINE HYDROCHLORATE, WHILE RELIEVING THE PAIN IN ACUTE OTITIS MEDIA, PROLONG THE CONGESTION?

This question occurred to the writer several times where he has used the remedy for relief of pain in the middle ear. He was satisfied that while cocaine relieves the pain and for a while holds the inflammation in check, after its effect has passed off the inflammation goes on unabated, even loss of hearing seems to be more intense.

DR. THEOBALD said that he had found that in the nasal passage the drug asserted the same effect. Though at first it relieved congestion, it was greater afterward.

DR. ORNE GREEN had derived very little benefit from its use.

DR. D. WEBSTER had seen decided benefit in the removal of polypi of the meatus.

EVENING SESSION.

DR. H. KNAPP, of New York, read a paper on

THE DESIRABILITY OF ADOPTING A UNIFORM METHOD OF EXPRESSING THE RESULTS OF TESTING THE ACUTENESS OF HEARING.

He said he differed from the opinion expressed by Bazold in a recent article published in the last number of the *Zeitschr. für Ohrenheilkunde*, that the ordinary speech and still more the whispered voice are the best hearing tests at present at our command. He thinks this test alone is insufficient for a correct estimate of the patient's hearing, as we would fail in many cases to detect the beginning of deafness, that stage when treatment is more important and more successful than in the later stages. The voice test should be supplemented by the test of the watch or Politzer's hammer. He, therefore, rejects Bezold's proposition to use the whispered voice as a uniform hearing test. Politzer's hammer he considers an excellent test, but, as Roosa remarks, it has no advantage over the watch. It has moreover the disadvantage, that its hearing distance, 15 metres, is too great.

Dr. Knapp proposes the use of the watch and the voice combined, the result to be registered in the manner proposed by Dr. Grout and himself thirteen years ago, as fractions of the normal standard, and gave a series of symbols, which he submitted to the Society for their consideration.

DR. ROOSA proposed that Dr. Knapp be requested to present the proposed system of recording the hearing to the meeting of German Naturalists at Strasbourg, next year, which was unanimously adopted, as also a motion by Dr. Orne Green, that a committee be appointed consisting of Drs. Knapp, Roosa, and Prout, to report in 1886 on a uniform system of recording the hearing power.

DR. D. B. ST. JOHN ROOSA, of New York, read a paper on

PRESBYKOUSIS.

This term was applied to senile impairment of hearing not dependent upon inflammatory affections. It comes on after the age of forty or fifty. Such persons do not hear well in a noisy room, and hear the watch badly, but they can hear quite well in a quiet room. In inflammatory diseases the person can often hear pretty well in a noise, while in a quiet room he hears badly. Three conditions go together, diminished bone conduction, hearing worse in a noise, and the disproportion between hearing the voice and the watch.

DR. KNAPP thought that the term presbykousis, if used in analogy with presbyopia, was not a good one, as it would indicate a diminished range of accommodation of hearing which would refer more to pitch than to anything else. What is meant is senile involution occurring in every organ.

DR. ORNE GREEN had been considering the subject some time and had arrived at the same conclusions as Dr. Roosa.

DR. HOLT had examined a large number of persons with ear disease who claimed they could hear better in a noisy than in a quiet room, but was unable to find that this was correct. He referred to a report of such observations made two years ago.

DR. ROOSA defended his position with regard to the term presbykousis, he said, with regard to hearing a noise, that he was convinced that patients with tympanic disease could hear better under such circumstances, and cited the example of a lady who heard with difficulty under ordinary circumstances, but in a boiler shop she heard the ordinary voice distinctly, while her husband with normal hearing, could only hear loud-spoken words.

DR. E. DYER, of Newport R. I., made a verbal report of a case of *Fistula Auris Externa* in a girl of fourteen relieved by galvanocautery.

The following papers were read by title:

Two Cases of Neglected Ear Disease in Infants, Resulting in Death, by Dr. S. Sexton, of New York.

A Case of Chronic Otitis Media Suppurativa Resulting in Cerebellar Abscess, with the Autopsy, by Dr. O. D. Pomeroy, of New York.

Digitized by Google

Otitis Media Suppurativa; Mastoid Disease and Pyæmia; Mastoid Operation; Recovery, by Dr. Graham Bacon, of New York.

Dr. Sexton exhibited a glass ear syringe and an ear forceps with several attachments.

The following officers were chosen for the ensuing year.

President.—D. J. S. Prout, of Brooklyn.

Vice-President.—Dr. S. Sexton, of New York.

Secretary and Treasurer.—Dr. J. J. B. Vermyne, of New Bedford, Mass.

Committee on Membership.—Drs. W. H. Carmalt, Ch. J. Kipp, S. Theobald.

Publishing Committee.—Drs. J. J. B. Vermyne, C. J. Blake, J. O. Green.

A vote of thanks to Dr. C. H. Burnett, the retiring President, for his excellent services was unanimously adopted, and the Society then adjourned.

AMERICAN OPHTHALMOLOGICAL SOCIETY.

Twenty-first Annual Meeting, held at Pequot House, New London, Conn., July 15 and 16, 1885.

(Specially reported for the MEDICAL NEWS.)

WEDNESDAY, JULY 15TH.—FIRST DAY.

MORNING SESSION.

THE PRESIDENT, DR. WILLIAM F. NORRIS, of Philadelphia, called the meeting to order at 10 A.M. After an address of welcome the usual committees were appointed.

DR. C. R. AGNEW, of New York, read an interesting paper on

A NEW OPERATION FOR THE REMOVAL OF A DISLOCATED CRYSTALLINE LENS.

The lens is transfixed by thrusting an instrument, consisting of two needles of a certain length, fastened in a Sand's needle-holder. A flap wound is made in the cornea, somewhat more extensive than in the ordi nary cataract operation. After the iridectomy the now fixed lens is removed with a scoop, without loss of vitreous. The procedure is simple, and Dr. Agnew thinks one need feel no hesitation in performing the operation. It is especially useful where the vitreous is watery. Dr. Agnew calls the instrument a bident. It was used on one case only, which resulted favorably.

DR. D. WEBSTER, of New York, followed in a paper in which negative results followed this same operation, admitting that it was on account of not being able to manipulate the instrument properly. The lens was delivered with a scoop with a slight loss of vitreous. The patient obtained $\frac{20}{C}$ vision. Dr. Webster remarked that the invention of the instrument will save many eyes which are now condemned to enucleation.

DR. H. KNAPP thought the operation an injurious one, and said that he had no trouble in extracting a dislocated lens by digital manipulation.

DR. E. WILLIAMS, of Cincinnati, expressed his appreciation of the invention of the instrument, but could not agree that the modus operandi is a good one at all times.

DR. H. W. WILLIAMS, of Boston, remarked that the removal of a dislocated lens is not difficult. When such cases present themselves, he usually dilates the pupil *ad maximum*, places the patient on his face, and allows the lens to gravitate into the anterior chamber. It can then be removed by a simple operation.

DR. ROOSA, of New York, explained (by request) his method of removal of a cataractous lens in its capsule. Forty-one cases operated upon showed two failures, which were, however, due to other causes.

DR. GEORGE C. HARLAN, of Philadelphia, then read a paper on

RAPIDLY PROGRESSIVE MYOPIA PERMANENTLY CHECKED BY SECTION OF THE EXTERNAL RECTUS.

He related the clinical history of a patient who, at the age of 16 years, wore a sph.—$\frac{1}{24}$ to render distant objects visible. Within the last year it was found that the myopia had increased, and asthenopic symptoms became very annoying. After an external tenotomy in one eye, the asthenopia was alleviated, and gymnastics of the muscles was instituted, which produced relief. Dr. Harlan remarked that the insufficiency could not have been the result of the myopia, as it was not affected by full correction; nor could spasm of the accommodation be a possible factor, as the degree of myopia was precisely the same. The asthenopia was not relieved by thorough mydriasis produced by atropia solution.

DR. HARLAN also reported

TWO CASES OF SUBCONJUNCTIVAL LUXATION OF THE LENS.

In the first case, the result of a blow with a fist, the lens was dislocated just above the cornea, in a vertical meridian. It was fixed in its position, the iris was drawn into the ruptured sclerotic, leaving the pupil irregular, and shreds in the vitreous. The eye was quiet. The lens was removed by making a horizontal cut through the tumor—at an examination three years later the eye was quiet and afforded useful vision.

The second case was a woman who received a blow from a piece of wood which she was cutting with an axe. The accident was followed by inflammation of the iris and sclera. It was decided to remove the encysted lens at once, which was done, and negative results followed.

Dr. Harlan's deductions were that in exceptional cases in which the eye remains useful after a subluxation of the lens it may be well to think twice before proceeding to operate.

DR. O. F. WADSWORTH, of Boston read a paper on *A Case of Luxation of Lens beneath Tenon's Capsule.*

DR. JOSEPH A. ANDREWS, of New York, read a carefully prepared paper on the

TREATMENT OF PURULENT CONJUNCTIVITIS.

The treatment advocated was based upon the belief that the contagious element of this disease is a variety of micrococcus. He related a case in which he had successfully inoculated the human conjunctiva with the seventh generation of a pure culture of the gonococcus. This is the first instance in which the human conjunctiva has been successfully inoculated with the gonococcus. He showed an instrument which he had devised for washing out the superior conjunctival cul-de-sac. The instrument consists of an eye-speculum with hollow arm, the claw having numerous perforations through which

Digitized by Google

fluid is forced by means of a fountain syringe connected with the instrument by means of a fine rubber tube five feet long. He found the bichloride of mercury in solution (1 : 10,000) serviceable, but apt to irritate; also the boracic acid solution (6 per cent.); carbolic acid solution 2 to 3 per cent. was a favorite, the latter remedy having the additional advantage that it inhibits the movement of the white blood-cells. Irrigation should be maintained for ten to fifteen minutes. The nitrate of silver, Dr. Andrews thinks, is a very valuable and almost indispensable addition. After the application of the silver he applies an antiseptic dressing to the conjunctiva consisting of vaseline and boracic acid, or carbolic acid. He laid especial stress upon the importance of maintaining the irrigation of the conjunctiva by means of the instrument above referred to.

DR. F. BULLER, of Montreal read a paper on

MELANOTIC SARCOMA OF THE ORBIT,

relating the clinical history of a patient who had the growth removed successfully with no recurrence elsewhere.

DR. E. E. HOLT offered for consideration some results obtained in the compilation of

A FIRST SERIES OF 1000 CASES OF REFRACTION.

He said he was in the habit of recording all measurements connected with the prescribing of glasses. As a result he had found in 1000 cases the average pupillary distance to be 60 mm. The average of other measurements was given and the importance of the oculist determining and designating them and having the optician follow the prescription accurately, was dwelt upon.

DR. C. R. AGNEW, of New York, read an abstract of a paper entitled

SIMULATED BLINDNESS,

based on the case of a young girl who simulated blindness for some time. The ophthalmoscope revealed no lesion, her pupils were sluggish however. A sudden alarm of fire produced sudden restoration of vision.

DR. THEOBALD had seen a similar case in which the pupils were active.

DR. B. E. FRYER, of Kansas City, read a paper on

BONY (CYSTIC) TUMOR OF ORBIT CAUSED BY AN ENCLOSED FOREIGN BODY.

He said that this case of bony orbital tumor is of interest from its pathology and from its diagnostic bearing on orbital growths generally. The patient was a colored boy, six years of age, free from hereditary taint and well developed. The tumor upon examination was found to be located just above the superciliary ridge, extending outwards as far as the external angular process of the frontal bone and projecting forward at the orbital edge about an inch higher than the bone on the other side. The tumor included the whole line of the ridge and extended downwards and backwards into the orbit, displacing the eye downwards, forwards, and outwards very markedly. The growth which was quite solid was too hard apparently for cartilage, and yet not dense enough for bone. The only history obtainable was that the boy two years previously had his forehead cut by a piece of wood thrust at him by another boy. The wound was slight, healed rapidly, and at time of examination showed no scar. The tumor began to appear after the injury and had been growing steadily since. No pain. An operation was performed May 1, 1885; a dense tumor, continuous with the frontal bone, of a whitish-yellow color and quite opaque, was found. This tumor proved to be a bony cyst enclosing a foreign body (piece of wood), one-fourth of an inch long, one-eighth of an inch broad, and one-twenty-fifth of an inch thick, with a small quantity of pus surrounding it. The tumor was successfully removed.

DR. MITTENDORF suggested that the wound injured the periosteum which, being displaced, formed the bony wall surrounding the foreign body.

DR. HARLAN called attention to the fact that inflammatory products may simulate a tumor of the orbit, and cited a case.

AFTERNOON SESSION.

DR. S. D. RISLEY, of Philadelphia, reported a group of seven cases, in addition to those already published by him, of

HYPERMETROPIC PASSING OVER INTO MYOPIC REFRACTION,

both conditions having been carefully determined after prolonged mydriasis. In five cases the meridian of lowest corneal curvature had been maintained. In two there had been a rotation of 10° in the principal meridians. Choroiditis was present in all the cases.

DR. RISLEY also reported a case of *Temporal Coloboma of the Choroid*, illustrated by a drawing.

DR. W. S. DENNETT read a paper on *The Examination of Spectacles*. This paper was illustrated with numerous drawings. He also exhibited the electric light ophthalmoscope. The light was about three-quarter candle power and was adjusted to the handle of the ophthalmoscope, the light being placed at such an angle as to allow its rays to be projected into the eye of the patient, giving an illumination not unlike the Argand burner. Its practical application is appreciated in the wards of a hospital.

DR. HOWE exhibited

AN ARRANGEMENT FOR THE DEMONSTRATION OF REFRACTION AND ACCOMMODATION.

This consists of two bands of thin metal, bent in such a manner as to represent the outlines of a double convex lens, and passing through it are two jointed rods, representing the rays of light ordinarily figured as passing through such a lens and joining at its focus; the flexible bands were attached to each other above and below, so that by approaching or separating the sides, they could be made to show less or greater convexity. The rods representing the rays of light were jointed near the centre in such a manner that, while the two halves could be placed in such a direction as to show the light as entering parallel to the axis of the lens, the other two portions could be bent to a point to show the convergence of rays at the focus. By alteration in the position of these rods, and also in the forms of the bands representing the lens, all the different variations of the laws of refraction, and the changes in accommodation, can be demonstrated to a class of students.

DR. BULL read a paper on *Two Cases of Lateral Hemiopia*, both the result of traumatism.

Digitized by Google

DR. HASKET DERBY, of Boston, reported

TWO CASES OF PENETRATION OF THE EYEBALL BY SCISSORS DURING THE OPERATION FOR STRABISMUS.

Case I.—A sharp-pointed scissors used which penetrated the globe, causing a slight loss of vitreous; wound healed slowly; patient was convalescent in six weeks; $\frac{7}{10}$ vision was ultimately obtained.

Case II.—A similar accident happening. A good recovery, with no defect of vision.

DR. H. KNAPP stated that he had met with three accidents of this kind. The functions of the eyes were not interfered with, the wounds healing by first intention. One case developed tenonitis, the cornea becoming complicated; divergent strabismus developed.

Drs. Williams, Mittendorf, and Buller each witnessed this accident.

DR. L. WEBSTER FOX, of Philadelphia, witnessed an operation for strabismus in which the sclera was punctured, a large quantity of vitreous escaping, producing prolapsus bulbi. Panophthalmitis developed, for which the eyeball was enucleated.

DR. E. E. HOLT, of Portland, Me., read a paper on

STRABISMUS; ITS CORRECTION WHEN EXCESSIVE, AND IN HIGH DEGREES OF AMBLYOPIA.

He had employed advancement of the weakened attenuated muscle, in connection with tenotomy, in certain cases of squint, after tenotomy alone had failed to correct the deviation.

DR. SEELY, of Cincinnati, in a paper on

THE TREATMENT OF STRABISMUS INTERNUS,

said that each year, with its added experience, had strengthened the conviction that early operations (up to 10th, 12th, or 15th year) are questionable, and possibly should be entirely abandoned. He combated the idea that "cross eyes" never became straight without an operation. He said, certainly nothing is better established than the relation between ametropia and strabismus, and all recognize the necessity of glasses for preventing the recurrence of the squint after tenotomy. Dr. Seely remarked: It must be strange if any man who has been in practice, even a decade of years, and has not seen divergence in cases said to have been perfect corrections of the internal squint for even a long period subsequent to the tenotomy; at any rate, if not divergence, insufficiency. Every one knows the possibility of correcting cases of squint by setting aside the ametropia by means of glasses. He did not believe many children now of four to six years of age were operated upon, in spite of all the teaching.

His early conviction, that something should be left for time and glasses, long since has grown into an absolute law of action, for he is thoroughly persuaded that immediate perfection means later in life insufficiency, or even divergence. He thinks that operative interference should not be the full consideration, but be looked on as an adjuvant to be resorted to later on if necessary.

He summed up his views as follows:

1st. That with our present light, routine operative interference is wrong.

2d. That to correct thoroughly the deviation in young children by operative interference is extremely liable to subject them in after-life to insufficiency or external squint.

3d. That a later period of life, if anything, favors better results from operative interference.

DR. RICHARD H. DERBY, of New York, read a paper on

ECTROPION OF UPPER AND LOWER LID, BLEPHAROPLASTY BY THE ITALIAN METHOD,

based upon a case in which, in consequence of a severe burn in childhood, there was complete ectropion of the lower lid, the upper lid was everted and its margin firmly adherent to the region of the brow; the eyelashes and eye-brow intermingled. The eye from constant exposure was the seat of frequent inflammation. About the eye and over the entire half of face, including the right half of forehead and temple was dense, firm, cicatricial tissue. For the relief of this condition there was no tissue which could serve for sliding flaps, and the tissue adjacent to the eye was so devitalized that a Wolfe's operation offered little prospect of success from the nature of the tissue which would surround the transported flaps. It was, therefore, determined by Dr. Derby to make a blepharoplastic operation according to what is known as the Italian method. The patient was a strong man and assented to the proposed operation which was done under ether. An incision was made along the margin of both upper and lower lid within one mm. of their edges. The incision was carried deeply enough to free both the upper and lower lids from their firm attachment. The margins of the lids were scored with the knife and then united by sutures. To fill this space now made over both upper and lower lid a flap four ctm. wide and eight ctm. long was dissected from the anterior and inner surface of the biceps region of the arm on the same side with the operated eye. This flap was divided by a linear incision in its length leaving two-thirds for the upper and one-third for the lower lid. The arm was now carried up to the head and put in position with the forearm extended over the head and there secured by bandage. The flaps were secured in place. The arm was then made fast by water glass bandage. Four days later the pedicle of the flap was cut through and the arm released. No accident followed. The patient has now a good upper and lower lid and fully-protected eye.

DR. W. F. NORRIS, exhibited for DR. CHARLES A. OLIVER, of Philadelphia, *A New Series of Metric Test Letters* based upon those of Snellen and De Wecker.

DR. B. JOY JEFFRIES suggested, in his article on

PLASTIC OPERATIONS WITHOUT PEDICLE,

the employment of the prepuce from circumcised children for the flaps. Also the possibility in some cases of not using flaps, and by the application of carbolized oil or a similar agent preventing the too-rapid healing of the wound.

EVENING SESSION.

DR. JAMES L. MINOR, of New York, read a paper on

REMOVAL OF A PIECE OF STEEL FROM THE CRYSTALLINE LENS WITH THE ELECTRO-MAGNET.

A small bit of steel which had been in the lens for a month was successfully removed with the aid of an

Digitized by Google

electro-magnet. The peculiarity of the operation consisted in magnetizing the instrument (strabismus hook), which was carried into the interior of the eye in search of the foreign body, by holding the point of the electro-magnet in contact with the shank of the instrument, throughout the operation. The point of the magnet holds the instrument firmly in contact with its tip which acting as a fulcrum allows a variety of movements and considerable delicacy of manipulation. This device, Dr. Minor says, enables the surgeon to operate with magnetized instruments. Reference was also made to an antiseptic method of dressing the eye which consisted in dusting powdered boric acid over the linen pad which covered the eye, previously to applying the cotton-wool packing for the bandage. The conjunctival secretions dissolve the acid and thus keep the eye under the constant influence of the drug.

DR. H. KNAPP, of New York, gave his experience, in a short paper, on

NINE SUCCESSIVE CASES IN WHICH THE ELECTRO-MAGNET WAS USED FOR THE EXTRACTION OF CHIPS OF IRON FROM THE INTERIOR OF THE EYE.

The cases were operated on during the last three and a half years. In two, the chip of iron was located in the iris; the one for two days, causing inflammation; the other for seventeen years. Quite recently both were successfully removed without any deterioration of the eye. In the seven remaining cases the foreign bodies were in the vitreous chamber, had produced cataract, and consequently could not be seen. In three cases the attempt at extracting them with the magnet did not succeed, and the eyeballs were enucleated. In four cases the chips of iron were brought forth at the first, second, or third introduction of the tip of the electro-magnet. In all of these four cases the recovery was good. All four are still cataractous; in two the form, size, and tension of the globe are not changed, and perception of light is good in the whole field; in the two others the globe is slightly smaller and softer, and the field of vision is defective, corresponding to the wound made for the extraction of the foreign body. No subsequent irritation developed while the patients were under Dr. Knapp's care.

DR. R. H. DERBY read notes and showed photographs of a case of *Congenital Malformation of the Upper Lid of an Infant*, with a history of an injury to the mother during pregnancy.

DR. A. MATHEWSON, of Brooklyn, read a paper on a

CASE OF EPITHELIOMA OF EYELID REMOVED BY APPLICATIONS OF BENZOLE AND CALOMEL.

The patient, aged 50 years, suffered with a tumor on the right lower lid, which was first noticed as a wart-like growth three years before, latterly rapidly increasing and presenting a new granulating surface covered with an easily removable concretion. Careful microscopic examination by an expert showed it to be an epithelioma. By frequent dusting of calomel on the raw surface, over which had previously been painted the common benzole, the growth entirely disappeared. A few months ago, a small granular elevation made its appearance at the edge of the cicatrix, where the first growth developed. Similar treatment produced like results.

DR. LUCIEN HOWE, of Buffalo, exhibited a manometer, and read a paper on

THE PULSATING VARIATIONS OF INTRAOCULAR TENSION AS MEASURED BY THE MANOMETER.

In calling attention to the variations of intraocular tension dependent upon the circulation, some attention also was given to the various forms of the manometer, or instrument for measuring the intraocular tension. The earlier instruments consisted simply in a U-shaped glass tube connected by a flexible rubber tube to a trocar. When the trocar was introduced into the anterior chamber of the eye, the intraocular pressure would tend to force the fluid through the tube, and show the degree of pressure by a rise in the opposite column of the U-shaped tube. This was imperfect, for the reason that when the aqueous humor escaped from the eye it was at once in an abnormal condition. The double manometer, described by Grasser and Holzke, obviated this difficulty. In this, however, there was an imperfection in the trocar, which was rather complicated and liable to get out of order. An improvement was accordingly suggested in having a stopcock attached to a needle of the hypodermic syringe, and this Dr. Howe found to serve the purpose much better than any heretofore used. The animal best adapted to this class of experiments is the cat, on account of the deep anterior chamber.

Dr. Howe stated that in the early experiments with the manometer it was noticed that the intraocular tension varied with the heart's action. In addition to this, the author called attention to the fact that these variations in the pressure, as indicated by the manometer, correspond to pulsations which can be seen with the ophthalmoscope in the vessels on the interior of the animal's eye. In other words, if the same thing holds in the human subject, we must infer that when pulsation is seen on the interior of the eye, there is also a variation of intraocular tension, which, although not enough to be detected by the touch or by any ordinary instrument, still exists. This connection between pulsation and pressure is a demonstration of the cause of venous pulse in the eye, as explained theoretically by Donders. Dr. Howe observed that after the introduction of the needle there was at first pulsation, but after a short time this ceased, the eye evidently adjusting itself to this unusual condition.

The experiments referred to were made by Dr. Howe in the laboratory of Prof. Zuntz, of Berlin, Germany.

DR. SAMUEL THEOBALD, of Baltimore, reported

THREE CASES OF PROGRESSIVE ASTIGMATISM OF TRAUMATIC ORIGIN.

Astigmatism of traumatic origin, he remarked, is observed not infrequently to undergo changes in degree, but it has been commonly held that congenital astigmatism does not alter in degree, though the refraction of the eye, as a whole, may undergo marked changes The cases which he reported, he thought, proved that there were some exceptions, at least, to this rule.

The first case related was that of a young man, who, with a high grade of hypermetropia, had an astigmatism in each eye, which required for its correction a cyl.$+\frac{1}{20}$. The case was observed at intervals during a period of twelve years, and during this time the astigmatism

Digitized by Google

increased until finally a cyl. $+\frac{1}{18}$ was needed to correct it.

The second case was one of compound myopic astigmatism in a young man, in which there occurred along with an increase of the myopia, a growth of the astigmatism during a period of sixteen years from $\frac{1}{16}$ to $\frac{1}{8}$.

In the third case, a simple myopic astigmatism, in a physician, 25 years of age, requiring a cyl. $+\frac{1}{24}$ in one eye, and a cyl. $+\frac{1}{30}$ in the other, for its correction; changed in five years so that a cyl. $+\frac{1}{18}$ respectively, were needed.

Dr. Theobald regretted that the examinations had not all been conducted under a mydriatic, as they would then be more likely to carry conviction to the minds of those disposed to be sceptical, regarding the progression of astigmatism, but he did not believe the results would have been materially different had this been done. Such cases are not of frequent occurrence, but even if they happen rarely, it is important that the fact should be recognized. As the increase of astigmatism is probably due to change in the corneal curvature, the phenomenon should be met with more frequently in the yielding myopic than in the relatively stable hypermetropic eye.

DR. H. S. SCHELL, of Philadelphia, read a paper on

LIPOMATOUS PTOSIS,

under which title he described cases of accumulation of fat in the upper eyelid. Four cases, all occurred in young women of 18 to 25 years of age. The patients were well nourished but not fat. The eyelids were so heavy that they covered one-half or more of the cornea in spite of the greatest effort of the levator muscle.

Patients all sought relief on account of the deformity. The fat, drooping lids gave a disagreeable, and, at the same time, a somewhat sinister and sensual expression to the face. Cases were all operated on by making a horizontal incision the length of the lid, half way between the margin and brow, and dissecting out the fat, which lies between the skin and the orbicularis. The ptosis usually disappeared in from one to four weeks. In one case the affection returned, and in the second operation a considerable mass of fat was removed from the upper part of the orbit.

DR. H. KNAPP, of New York, read a paper on

THE TREATMENT OF CORNEAL INFILTRATION WITH THE ACTUAL CAUTERY.

The use of the actual cautery, he remarked, in destructive corneal processes, was introduced by Dr. Martinache, of San Francisco, in 1873; by the introduction of cocaine it has received a new impetus. Recent publications on the subject by Drs. Nieden, Schweigger, Grüning, and others, recommend its use. Dr. Knapp has used it, under cocaine, in nineteen cases. The majority were cases of pustular keratitis; one with hypopyon was that tedious form known under the name of scrofulous band. The recovery in this group of cases was rapid and highly satisfactory. Four cases of ulcus serpens, one deep with a high degree of hypopyon were treated. The latter was cured in five weeks, the others were benefited, though their recovery was not so rapid. In a case of acute suppuration of an old prolapse of iris, a single cautious application of the actual cautery did not prevent the development of panophthalmitis so common in such cases. In two cases of beginning suppuration of the edges of a cataract extraction wound, the application of the actual cautery, proposed by Abadie, had no apparent effect, the milder case recovered, the severer one developed into panophthalmitis.

Dr. Knapp, from the study of the incidental literature and from his own, though yet limited, experience, feels confident that the actual cautery will prove of great value in ophthalmic therapeutics.

DRS. E. WILLIAMS and O. F. WADSWORTH obtained good results by applying carbolic acid (pure) to the ulcers.

Several members stated that they scraped away the destructive tissue and in this way brought about resolution.

DR. L. WEBSTER FOX, of Philadelphia, presented some

CLINICAL OBSERVATIONS.

First. Congenital cataracts successfully removed in a patient sixty years of age. On February 4, 1884, Harriet H——, negress, presented herself at the Eye Clinic of the Germantown Hospital, suffering with cataracts. The lenses were opaque with well-marked deposits of calcareous concretions situated in the anterior or visible portions of the lenses.

Upon examination good projection of light obtained. The history elicited was that since birth the vision had not changed, simply being able to distinguish day from night or the light of a lamp, or the shadow of a dark object when brought directly in front of the patient's face. Feeling assured of the sensibility of the retina, an operation for the cataract in one eye was suggested, and was performed. The lens was successfully removed in its capsule with a Critchett's spoon. There was a small loss of vitreous, which was fluid. The eye was closed immediately, and the wound healed without reaction; the eye being bathed daily with a mild astringent lotion, but the lid was not disturbed.

At the end of eight days the bandages were removed when it was found that the wound was closed and a key-hole iridotomy existed which was perfect in outline and showed a clear media. The patient was astonished, she could see objects several feet distant but was quite at a loss to understand the visual phenomena. She was quite nervous from the effect of the shock and started violently and closed her eyes as if with fear. She was unable to name any object placed before her but readily distinguished it when her hand was placed upon it. A few moments afterward she readily distinguished a watch which was shown her. This was distinguished not by its form, but by its ticking. At this time wools of different colors were placed before her and a certain one given to be matched, which was done without confusion, proving the accurate sensibility of the retina to the most delicate tints, although not a name was known to the patient. After several days the object and wool test was made again. When looking at a distance—for she could recognize objects at a distance, the refraction of the eye before the operation being myopic to eleven dioptrics—she tried to grasp the objects, and a flock of sparrows were supposed to be tea-cups. Owing to her first impression of distances she was for quite a time afraid to walk with her eyes open, the floor appear-

Digitized by Google

ing at a distance. A red and black color produced pain in the eye-ball while green and white were soothing. After the bandages were removed she was allowed the freedom of a moderately lighted room to become accustomed to those objects about her, as well as to learn to measure distances; she repeatedly refused to walk, although the nurse assured her that no danger would befall her in the effort.

The patient was soon able to associate the name with the object and at the end of some weeks, in the meantime using her eye constantly, she was able to mention all the objects in the ward of the hospital, but at times would make mistakes quite as ludicrous as the birds with the tea-cups. Her vision without glasses is equivalent to $\frac{20}{XX}$ and with sph. +1 she is able to see fine stitches which would be equal to J $\frac{2}{10''}$. In January of this year the right eye was operated on; no reaction followed, and she is now able to see perfectly with both eyes.

Her color fields were accurately measured at different times and found to correspond to Landolt's measurements. The fundus oculi presents a peculiar picture. The disks are oval in shape, while the distribution of vessels are few in number and do not extend beyond the equator—they run into capillaries and were not recognizable with the ophthalmoscope. The lenses were found to be only two-thirds the size of an ordinary adult lens. Instead of being convex in shape, they were found to be almost spheroidal. The patient is now employed as a general servant in the hospital.

Obs. II.—Recovery of vision after eighteen years of blindness. Vision after operation $\frac{5}{CC}$ increased by a glass = sph. + $10\underline{D} \supset$ cyl. + 3, D ax. 180 $\supset$ cyl. + $2\underline{D}$ ax. 50° (ground in one) = $\frac{20}{XX}$. Reading sph. + $14\underline{D} \supset$ cyl. + 1.50 ax. 50° J$\frac{1}{10}$

R. L., woman, 37 years, at three years of age was injured in the left eye, two years subsequently sympathetic ophthalmia developed, leaving the right eye with qualitative perception of light only. At various times she had operations performed by distinguished surgeons with negative results.

On June 21, 1884, at the Germantown Hospital, an iridotomy was performed; a large ovoidal-shaped pupil with a clear media was the result of this operation.

This patient, who had at one time good vision, was annoyed at the "confused look" of surrounding objects. The erythropsia (seeing everything red) was so great that dark glasses were ordered to be constantly worn. After three months this retinal trouble disappeared, and objects assumed a natural color.

After repeated examination the formula above referred to was prescribed, the glasses giving almost perfect vision. The patient (educated at a blind asylum) has presented me with her first impressions, in writing, of the living and inanimate objects surrounding her, and her mental conception of objects conveyed through the medium of touch, was as unlike that received through the now restored organ of vision as day from night.

Dr. Fox then related the history and treatment of five cases of retinitis pigmentosa.

These cases were treated by electricity (constant current five cells), and showed marked improvement in fields of vision and central vision. One patient after non-treatment for nine months (purposely) still retains the fields gained by the treatment. Dr. Fox found five cells sufficiently powerful to produce good results. The positive pole is placed over the eye, lid closed, and negative on the nape of the neck.

Obs. III.—The clinical histories of two cases of monocular optic neuritis, in which the histories are irrelevant, but good acuity of vision was obtained by small and continued doses of mercury. Both cases were young girls about sixteen years of age.

Obs. IV.—Sarcoma of iris successfully removed and $\frac{20}{XXX}$ given by cyl. + 3.50 ax. 45 $\supset$ cyl. — 4 ax. 165°. The growth was noticed as far back as July, 1884. After this time glaucomatous symptoms became manifest. Iridescent colors and increased tension were observed. The vision at one of these subacute attacks became nearly indistinct. After an interval of two months patient had another attack, the eye becoming blind and remaining so for six hours. The acuity of vision in the interval constantly growing worse, and the tension becoming more manifest at the time of the operation, February 11, 1885,

V. R. E. $\frac{20}{LXX?}$ no improvement c glasses (sarcoma).

V. L. E. $\frac{2}{C}$ injured one.

The wound was made precisely like the old flap operation for cataract. With an iris forceps the tumor and a large piece of the iris were seized, which were then excised; good results followed. The choroid of the left eye was ruptured by a blow in 1872, which accounts for the low degree of vision.

THURSDAY, JULY 16TH.—SECOND DAY.

MORNING SESSION.

DR. W. F. MITTENDORF, of New York, read a paper on

PNEUMOPHTHALMOS, OR AIR IN THE VITREOUS HUMOR.

He remarked that the entrance of air into the interior of the eye will occur at times during an operation. In such cases the air may get into the anterior chamber, whence it can be removed with ease. It is entirely different when air gets into the vitreous chamber. The accident is of such rare occurrence, that, so far, no description of it has been given. Dr. Mittendorf reported two cases. The first case was that of young blacksmith, who was wounded by a piece of iron penetrating the sclera and lodging in the vitreous humor. After a few hours it was found that the foreign body, surrounded by a clot of blood, had settled at the bottom of the eye, the vitreous had cleared up, and behind the lens, and a little above it, three air-bubbles were seen by means of the ophthalmoscope, one of these appeared to be the size of a small pea, the two smaller ones were about as large as a rape-seed. They resembled the air-bubbles as seen under the microscope, their centre being bright, and the outline so well defined and surrounded by a sharp black border, that their recognition

Digitized by Google

was not difficult, although none of the gentlemen that looked at the case had ever seen anything like it in the interior of the eye.

The foreign body could not be removed by means of the magnet, and it was decided to let it remain. The eye was bandaged, and at an examination the following morning it was found that the bubbles had coalesced, and a large bubble was now located at the posterior pole of the lens, the patient having remained quietly on his back sometime before examination. The upright position caused the bubble to float upwards, and settle at the dome of the eye. Forty-eight hours after the accident every trace of the air-bubbles had disappeared.

The second case was the result of a drilling accident, and represented in outline the same characteristics.

In order to determine the exact appearance of air in the vitreous humor, Dr. Mittendorf experimented upon rabbits' eyes. Four had air introduced into the vitreous humor by means of a hypodermic syringe, while four were subjected to introduction of oil by the same means. Nearly all these experiments were successful. The difference between the air-bubbles and oil-globules was marked. The oil-globules were highly refractive, the contour decidedly darker than the air-bubbles, which were colorless. Dr. Mittendorf's conclusions were:

1. The entrance of air into the vitreous body can occur only after a part of the contents of the vitreous chamber has escaped.

2. It is favored by the entrance of a foreign body which makes a large, irregular, and gaping wound in the sclera.

3. In order to allow air to enter the vitreous humor, this must either be quite fluid, or its anatomical arrangement must have been disturbed by the entrance of a foreign body, or the air must have been attached to the foreign body, and thus carried with it into the eye.

4. The air in the vitreous humor appears like an air-bubble as seen under the microscope; it is more or less round, highly refractive in the centre, and has a sharply defined black outline.

5. Oil-globules in the vitreous present a similar appearance, but they look heavier, and are not perfectly colorless, and their outlines are darker; they are also more glistening in the centre.

6. Air-bubbles will be completely absorbed within two or three days; their presence is not a source of great danger to the eye. Oil-globules last longer, but their presence is likewise non-irritating.

DR. W. F. NORRIS, of Philadelphia, read a carefully prepared paper on

THE RELATION BETWEEN THE EARLIER STAGES OF GRAY DEGENERATION OF THE OPTIC NERVE AND INCREASE OR DIMINUTION OF THE PATELLAR TENDON REFLEX.

The clinical histories of the patients were discussed, and their fields of vision shown.

DR. E. WILLIAMS remarked that he had had patients in whom he failed to trace the atrophy to spinal trouble. He felt sure that taking large and repeated doses of quinia would produce amaurosis.

DR. MYLES STANDISH, of Boston, read a paper on

A CASE OF TUBERCLE OF THE IRIS.

The patient, a girl of 14 years, her parents living, and without any history of syphilitic or tubercular disease, was, however, anæmic, and poorly developed. A growth, 2 mm. in diameter, of pink color, with small vessels on its surface, projected from the surface of the iris near its ciliary border. There was posterior synechiæ, which were not broken by mydriatics. In one month the growth had doubled in size, the iris remaining perfectly quiet. The eye was removed at the Massachusetts General Hospital, and a microscopic examination of the tumor was made by an expert, who pronounced it tubercle of the iris.

DR. G. C. HARLAN exhibited for Dr. Jackson, of Philadelphia,

A NEW REFRACTION OPHTHALMOSCOPE.

The main features of this instrument is the absence of Rekoss's disk, the lenses are placed in two narrow slides, which move vertically behind the mirror and in front of the disk, thus obtaining a range from sph. + 9 D to sph. — 14 D inclusive, with an interval of 1 D.

DR. W. S. DENNETT, of New York, showed

THE STOKES LENS FOR MEASURING ASTIGMATISM.

These lenses were supported by a frame in such a way as to be easily adjusted in the place of the ordinary trial frame, and he gave in detail the simplest method of fitting glasses by it. Dr. Dennett showed that the instrument was so easily manipulated that the patient could assist greatly in the examination. The strength of cylinder and inclination of its axis could be read from the instrument, and the method of correction for the spherical element which entered into the Stokes combinations, was so simple that any one who would write it on a tag and attach it to the machine, would probably never need to refresh his memory by looking at the tag.

DR. C. J. KIPP, of Newark, N. J., reported

A CASE OF CONGENITAL COLOBOMA OF IRIS, CHOROID, AND RETINA,

in which inflammatory glaucoma developed late in life; with an anatomical description of the eye. The eye was enucleated to relieve pain. The coloboma was found to extend through to the optic nerve. The ciliary bodies were intact, but irregular as to the arrangement of their processes. There was a large ectasia of the sclerotic, over this the choroid and retina were wanting. There was a deep glaucomatous excavation of the optic nerve.

DR. O. F. WADSWORTH, of Boston, reported an interesting

CASE OF DOUBLE OPTIC NEURITIS AND OPHTHALMOPLEGIA FROM LEAD POISONING,

complicated with typhoid fever. He remarked that the patient, a boy 9 years of age, had suffered with obscure febrile symptoms for several weeks, and movements of the left eye had been observed to be imperfect. When first seen by Dr. Wadsworth there was pronounced optic neuritis in both eyes, vision was much diminished. No lateral movements of left eye, movement downward impaired; movement of right eye outward defective. Probable diagnosis, tumor in region of pons.

The movements of the eyes became still more impaired and vision sank. The patient developed fairly distinct symptoms of typhoid; spleen and liver both enlarged. Lead was found in the urine, and diagnosis of tumor abandoned. Treated with potass. iod., general

Digitized by Google

conditions became normal; the neuritis passed into atrophy, leaving too little vision to count fingers; the movements of the eyes were completely restored; the lead disappeared from the urine.

DR. B. JOY JEFFRIES, of Boston, offered the following resolution concerning

STANDARD COLOR SIGNALS,

which was unanimously adopted:

Resolved, That the Society would again express most hearty approval of the International Commission, twice recommended in a bill reported by the Naval Committee of Congress, and endorsed by the International Medical Congress of London, 1881; to consider and agree upon standard colored lights and signals, etc.; and the visual power and color sense of officers and sailors.

The Society would particularly support the International Congress, and vote that "every government, especially the maritime governments, should be requested to place one or more members on the commission, and chiefly experienced naval officers and medical specialists.

The Secretary is hereby directed to transmit this vote to Congress.

DR. SAMUEL THEOBALD, of Baltimore, offered the following resolution concerning the

NEW ORGANIZATION OF THE INTERNATIONAL CONGRESS.

Resolved, That it is the sense of the American Ophthalmological Society, that the action of the American Medical Association, at its late meeting in New Orleans, and of the enlarged committee appointed at that time to make arrangements for the International Medical Congress, in overturning much of the carefully planned work of the original committee appointed at Washington, for the same purpose, was unwise, and not to be defended, unless, possibly, upon technical grounds; and this Society hopes that none of its members will endorse the action of the enlarged committee by accepting official positions at its hands.

DR. E. WILLIAMS, of Cincinnati, voted against the measure, on account "of not wishing to goad a sick horse." He understood that he was appointed by the new committee president of the Ophthalmological Section, but up to the present time he had not been notified, and hence had not yet tendered his resignation.

DR. KIPP spoke against the resolution.

The resolution was adopted by a large majority.

The meeting was highly satisfactory to the members present, a larger number participating, and a larger number of papers were read than at any previous meeting. It was decided to hold the Twenty-second Annual Meeting at the same place in July, 1886.

NEWS ITEMS.

CINCINNATI.

(*From our Special Correspondent.*)

THE INTERNATIONAL MEDICAL CONGRESS AND THE MEDICAL PROFESSION OF CINCINNATI.—The members of the profession in Cincinnati and its vicinity who were appointed to office by the Chicago Committee, on July 17th adopted the following preamble and resolution:

Whereas, The recent action of the American Medical Association with reference to the organization of the proposed International Medical Congress was, we believe, detrimental to the best interests of the Congress, therefore,

Resolved, That we, the undersigned, nominated members of the Congress, hereby decline to serve.

P. S. Conner,	J. C. Reeve,
F. Forchheimer,	W. W. Seely,
S. Nickles,	J. T. Whittaker,
Thad. A. Reamy,	E. Williams.

MORE RESIGNATIONS FROM THE NEW ORGANIZATION.—We are informed that Dr. W. A. Hardaway, of St. Louis, has declined the Presidency, and Dr. J. Nevins Hyde, of Chicago, the Vice-Presidency, of the Section of Dermatology and Syphilis in the new organization of the Congress; that Dr. E. Williams, of Cincinnati, declines the Presidency of the Section of Ophthalmology; and that Drs. T. A. Reamy, of Cincinnati, and J. C. Reeve, of Dayton, Ohio, have declined Vice-Presidencies in the Section of Obstetrics and Gynecology.

Drs. George M. Sternberg and R. W. Shufeldt, U. S. A., E. Van de Warker, of Syracuse, N. Y., and William Lee, of Washington, J. M. Keating and George E. De Schweinitz, of Philadelphia, have also declared their intention to decline office.

Dr. N. Senn, of Milwaukee, has resigned from the General Committee.

THE INTERNATIONAL MEDICAL CONGRESS AND THE AMERICAN OPHTHALMOLOGICAL SOCIETY. — At the annual meeting of the American Ophthalmological Society held at New London last week, the following resolution was adopted.

Resolved, That it is the sense of the American Ophthalmological Society that the action of the American Medical Association at its late meeting in New Orleans, and of the enlarged Committee appointed at that time to make arrangements for the International Medical Congress in overturning much of the carefully planned work of the Original Committee appointed at Washington for the same purpose, was unwise and not to be defended, unless, possibly, upon technical grounds; and this Society hopes that none of its members will endorse the action of the enlarged Committee by accepting official positions at its hands.

PUBLIC OPINION ON THE WORK OF THE CHICAGO COMMITTEE.—The exclusion from representation in the Congress of the great bulk of the profession, including a large number of the brightest lights of American medicine, seems, not to put it too harshly, like a piece of unwarrantable assumption.

The effect of this action of the Committee remains, of course, to be seen, and can only be conjectured. That it has not met the approval of even all of the appointees of the Committee has already transpired. . . . . Perhaps and doubtless, the thirty-eight States and territories of this Union will be able to get along without the gentlemen whom the Committee have excluded, and who have excluded themselves; but can a meeting with such material left out be said to be thoroughly representative of the medical profession of the United States? The

Digitized by Google

action of the European profession in the premises, remains to be seen.—*Medical Age* (Detroit).

The past week has brought no news calculated to reassure those who are anxious for the success of the International Medical Congress and the credit of American medicine. Nearly all the gentlemen appointed on the organization from Boston, Philadelphia, Baltimore, and Washington have withdrawn, while many prominent men in New York (aside from those forced off) and from the West will, we learn, either formally withdraw, or informally decline to take any part in the work.

The comments of the medical press are almost uniformly condemnatory of the folly and short-sightedness of the American Medical Association. . . . . A meeting of the American Medical Association, entirely revoking its New Orleans work, and restoring the old Committee, with its liberal policy, might, perhaps, save the Congress. We see, at present, no other way.—*Medical Record.*

It has unquestionably become the duty of every well-wisher of the Congress, no matter where he may live, to decline any participation in the emasculated affair, which its present organization must necessarily lead to.—*New York Medical Journal.*

The very fact that the appointees of the original Committee in all parts of the country have acted with such unanimity in withdrawing from prominent positions in connection with the Congress, and have repudiated the action of the present Committee on Organization, is sufficient evidence that there were strong and unimpeachable reasons for their conduct in this matter. . . . . The withdrawal of the leading members of the profession from all connection with the present organization tells its own story, and very plainly says, the Congress must be reorganized on some other basis than the one proposed by the American Medical Association if it is to be a success. In other words, the Association has so seriously blundered in this affair that it must resign its authority as a leading spirit in the reorganization of the Congress. Indeed, it seems to us that the only course now left open to the Association is to abstain from further participation in the arrangements for the Congress, and that it leave this matter in the hands of the medical profession at large, which can be depended on to reorganize the Congress on a successful basis.—*Maryland Medical Journal*, July 18, 1885.

The spirit of dissatisfaction has not been quieted, and the outlook for a harmonious reception of our foreign brethren is decidedly dark.—*Northwestern Lancet*, St. Paul.

No sooner were the proceedings of the Chicago meeting made known than the members of the profession in the eastern cities interested in the organization met and expressed their emphatic disapproval of the action by unanimously refusing to have anything to do with the Congress under the present *regime*. We happened to be in Philadelphia on the occasion of the meeting in that city, and found that the leaders of the profession were of one mind in their determination to withdraw. Similar resolutions have been passed in Boston and Baltimore, and we may say that the majority of the men, eminent in scientific medicine and surgery in the United States, have decided to hold aloof from the Congress. When we ask why they take this serious step, we learn that they have, in the first place, a deep distrust of the American Medical Association as an organization which could satisfactorily carry out such an undertaking, and they have a still deeper distrust of the success of any congress where the best known scientific medical men of the country have been replaced by nominees such as Drs. Cole, Shoemaker, and others. All, too, resent the insult offered to such a veteran as Henry I. Bowditch, of Boston, who has devoted half a century to the advancement of the best interests of the profession in the United States.

What the result will be it is difficult to predict, but it is hard to see how a Congress can be held without such men as those who have signified their intention of resigning. It would be like a Congress in London without Paget, Lister, Jenner, Gull, Hutchinson, etc., and we fear that when the profession in Europe hears of these dissensions, and the withdrawal of the very men they would be most anxious to meet, many who otherwise would have come will elect to stay away.—*Canada Medical and Surgical Journal.*

There is a very unfortunate discussion going on at present in professional circles in America, which, it is quite possible, may turn out disastrously for the International Medical Congress, which it has been decided to hold in Washington in 1887. It will be remembered that a small Committee of the American Medical Association was nominated by the Executive of the Copenhagen Congress, with full power to add to their number, and to act on behalf of their professional brethren. Carrying out their mission, they chose as colleagues twenty-eight leading American practitioners, especially selected on account of their standing in the profession, and drew up the programme which has already been published. Subsequently, when the Committee reported to the meeting of the American Medical Association at New Orleans, exception was taken to their proceedings on the plea that they had exceeded their powers, and had no commission to act on behalf of the Association. The jealousies that had been roused amongst those who had been passed over in the coöptative selection were worked upon by two or three pushing wire-pullers, and, in the end, resolutions were passed revising the work of the Committee, and substituting a Committee of thirty-eight men, selected from the different States and territories, for those added to their number by the original Committee. At a subsequent meeting, the results of which we are daily expecting to hear, the subject was again to come under consideration, and we learn that it was the intention of all the leading practitioners in the States to withdraw from the Congress, if the decisions of the original Committee were not treated with more respect. We sincerely hope that the profession in America will strenuously support their recognized leaders; otherwise they will make an exhibition of themselves to the world, and, besides imperilling the future success of those international gatherings which have hitherto been conducted with so much harmony, will distinctly lower the respect in which the profession is held throughout the world.—*Medical Times and Gazette* (London).

IMPORTANT, IF TRUE.—The *Maryland Medical Journal*, in its issue of last Saturday, states that "it is currently rumored in this city that the International Medical Congress and the American Medical Association have been captured by one of the New York schools, and will

Digitized by Google

be run under its exclusive patronage. 'Madam Rumor' is not always an unreliable witness."

THE MUHLENBERG MEDICAL SOCIETY, of Tennessee, was organized in Central City on Wednesday, July 9, 1885. Dr. J. G. Bohannon was elected President; Dr. W. E. Irvin, First Vice-President; Dr. J. T. Woodburn, Second Vice-President; Dr. J. W. McDowell, Recording Secretary.

The Society will meet the first Wednesday in each month at some town in the county. The Society will next meet at South Carrollton, August 5th, at 10 o'clock A.M. Dr. J. T. Woodburn, of Bremen, will read a paper on "Cholera Infantum."

TYROTOXICON, CHEESE POISON.—At the meeting of the Michigan State Board of Health, July 14, 1885, DR. V. C. VAUGHAN presented a report of his investigations on poisonous cheese. It is well known that cases of severe illness follow the eating of some cheese. Such instances are of frequent occurrence in the North German countries and in the United States. In England they are less frequently observed; while in France, where much cheese is made and eaten, these cases are said to occur very rarely. A few years ago the reputation of a large cheese factory in northern Ohio was destroyed by the great number of cases of alarming illness from eating its cheese. Dairymen know this cheese as "sick" cheese.

Kinds of Cheese that are Poisonous.—A German author says: "The numerous kinds of soft cheese, prepared in small families, or on small farms, are generally the cause of the symptoms; while it is quite exceptional to hear of symptoms arising from the use of cheese prepared in large quantities." Some two years ago, a family in Alpena, Michigan, was poisoned by eating of cottage cheese; the cheese which poisoned so many in this State last year, was made at one of the largest factories in the State, and by an experienced cheese-maker. The old foul-smelling cheeses, such as Limburger and Schweitzer, have never been known to be poisonous.

Effects of the Cheese.—The symptoms produced by "sick" cheese, as reported by German and American physicians, agree quite closely, and are as follows: Dryness of the mouth and throat with a sense of constriction, nausea, vomiting, diarrhœa, headache, sometimes double vision, and marked nervous prostration. In rare instances the sufferer dies from collapse. As a rule, recovery occurs in a few hours, or at most after a few days. The symptoms of cheese-poisoning and those of sausage, canned-meat and fish poisoning, are very similar. Though death results more frequently from the others mentioned than from cheese-poisoning.

Appearance of the Cheese.—The samples of cheese examined had no peculiarities of appearance, odor, or taste, by which it could be distinguished from good cheese. It is true that if two pieces of cheese—one poisonous and the other wholesome—were offered to a dog or a cat, the animal would select the good cheese. But this was probably due to an acuteness of the sense of smell possessed by the animal and not belonging to man. Indeed, if a person tasted a cheese, knowing that it was poisonous, he might detect a sharpness of taste which would not ordinarily be noticed.

Have we any Ready Means of Recognizing Poisonous Cheese?—There is no certain means, aside from a chemical examination, by which a poisonous cheese can be distinguished from a wholesome one. The most reliable ready method is probably that proposed by Dr. Vaughan a year ago, and it is as follows: Press a small strip of blue litmus paper (which can be obtained at any drug store) against a freshly-cut surface of the cheese. If the paper is reddened instantly and intensely, the cheese may be regarded with suspicion. When treated in this way, any green cheese will redden the litmus paper, but ordinarily the reddening will be produced slowly and will be slight. If the piece of cheese be dry, a small bit should be rubbed up with an equal volume of water, and the paper should then be dipped in the water. Dr. Vaughan does not regard the above test as free from error, but as the most reliable ready means now known. Every groceryman should apply this test to each fresh cheese which he cuts. The depth of the reddening of the paper may be compared with that produced by cheese which is known to be wholesome.

Effects on the Lower Animals.—Dogs and cats, at least, are not affected by eating poisonous cheese. This is probably due to the fact that they do not get enough of the poison from the amount of cheese which they eat. The pure isolated poison in sufficient doses would undoubtedly produce upon the lower animals effects similar to those produced on man.

Nature of the Poison.—Dr. Vaughan has succeeded in isolating the poison, to which he has given the name tyrotoxicon (from two Greek words which mean cheese and poison). It is a product of slight putrefaction in the cheese, which probably occurs in the vat, as the curd has been known to poison a person. By this slight putrefaction, or excessive fermentation, as it may be called, a large amount of butyric acid is formed, and this in the presence of the casein of the cheese is capable of developing a poison. Different samples of poisonous cheese contain different amounts of the poison. The same weight of cheese from one cake furnished three times as much poison as that from another cake. The poison was obtained in long, needle-shaped crystals, which are freely soluble in water, chloroform, alcohol, and ether. The smallest visible fragment of a crystal placed upon the end of the tongue causes a sharp, stinging pain at the point of application, and in a few minutes dryness and constriction of the throat. A slightly larger amount produced nausea, vomiting, and diarrhœa. The poison is volatile at the temperature of boiling water, and for this reason even poisonous cheese may be eaten with impunity after being cooked. The substance has also a marked, pungent odor, and through the nose one can obtain sufficient of the volatile poison to produce dryness of the throat. This is true, however, only of the isolated poison. In the cheese the taste and odor of the poison are both modified to such an extent that they would not be recognized, as has already been stated.

The first step in the study of cheese poisoning has now been taken, by finding out what the poison is. Efforts will be made to ascertain the means for preventing its formation.

FERRÁN'S CHOLERA INOCULATION.—The pilgrimage of Professor Brouardel and his companions to the feet of the great Western Sage, who professes to stamp out

Digitized by Google

the most formidable of modern epidemics, has produced the most startling and unexpected results. Dr. Ferrán positively refused to make known his method of preparing the fluid, the inoculation of which, he claims, preserves from cholera. He would not allow the French Commission to carry off even a single tube of vaccine matter for the purpose of examining it under the microscope, and refused to sanction any experiment outside of his "laboratory." The place dignified with that high-sounding name possesses none of the modern appliances of science, not even an apparatus for regulating the temperature of the stove in which the cholera virus is cultivated for attenuation. The single microscope available within its precincts only possesses a magnifying power of 700 diameters, while in all modern laboratories of bacteriology magnifying powers of 1200 or 1400 diameters are considered indispensable. We must admire the genius of investigation which led Dr. Ferrán, with such imperfect means, to achieve such portentous discoveries; but we cannot laud the spirit in which he told the French Commissioners that he could not surrender his secret without "a guarantee." The meaning of this expression was clearly indicated by the Doctor himself, in a letter officially addressed to the (French) Minister of Trade, in which, after deploring the indifference of his native country, which, unlike France and Germany, grants no pecuniary reward to its men of science, he openly says, "All the fame in the world would not preserve my children from poverty if death should overtake me."

It sems fair that, before granting Dr. Ferrán a "*substantial*" reward, the Spanish Government should make sure that there exists a "*substantial*" discovery. The French Commission could not solve the problem, as the Doctor had no microscopical preparations to show them, and would not grant them permission to make any of their own. They had, therefore, no means of controlling Dr. Ferrán's startling announcements as to the mode of reproduction of the cholera bacillus, nor of making experiments upon living animals. All they could do was to attend the Doctor in some of his "*vaccinations*," and to examine the statistical data which seem to plead in favor of his system. Dr. Ferrán inoculated, in presence of the Commissioners, a certain number of Sisters of Charity. He injects the contents of a full syringe (one cubic centimetre) into the back part of each arm. No antiseptic precautions are taken, and the air contained in the syringe is not even expelled before the injection takes place. The results are a slight malaise, with lowering of the temperature; no fever, no vomiting, or diarrhœa. It must be allowed that, on the whole, no bad effects seem to follow the injection. The blood of persons inoculated contains no abnormal elements.

The statistical data, which at first sight appear to confirm Dr. Ferrán's statements, are, upon further investigation, found to be altogether unreliable. The population of Spanish towns is always understated, in order to avoid taxation; the number of deaths is also understated, especially in times of cholera, in order to avoid the much-dreaded sanitary "cordon." No reliance, therefore, can be placed upon the figures, which seem to prove that vaccinated and revaccinated subjects are less liable to infection than others. Besides, it is well-known that in all countries cholera is less frequent among the more prosperous classes of society than among the poor. Now, the poor are properly not to be reckoned among vaccinated subjects, since Dr. Ferrán's charges vary from four to ten shillings. As the Doctor is said to vaccinate from 500 to 600 persons daily, the operation would seem not to be altogether unprofitable, and the "*guarantee*" which Government refuses is evidently drawn from the public. It may, therefore, safely be concluded, as Professor Brouardel remarks, that Dr. Ferrán has far too hastily stepped out of the scientific and experimental period into the period of what he calls "*practice*." Compare with his rashness the extreme prudence of Pasteur! Yet, the French physiologist operated upon cattle, and not upon man.—*Medical Times and Gazette*, July 11, 1885.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 14 TO JULY 20, 1885.

VOLLUM, E. P., *Lieutenant-Colonel and Surgeon.*—To be relieved from duty in Department of the East on the expiration of his present leave of absence, and to report to Commanding General Department of the Platte for assignment to duty as Attending Surgeon at the headquarters of that department.—*S. O. 159, A. G. O.*, July 14, 1885.

MIDDLETON, J. V. D., *Major and Surgeon.*—Leave of absence extended fifteen days.—*S. O. 159, A. G. O.*, July 14, 1885.

BROWN, J. M., *Major and Surgeon.*—EWEN, CLARENCE, *Captain and Assistant Surgeon.*—TAYLOR, A. W., *Captain and Assistant Surgeon.*—BORDEN, W. C., *First Lieutenant and Assistant Surgeon.*—Ordered to prepare for field service..—*S. O. 64, Department of the Platte*, July 9, 1885.

ELBREY, F. W., *Captain and Assistant Surgeon.*—Sick leave of absence further extended four months on surgeon's certificate of disability.—*S. O. 162, A. G. O.*, July 17, 1885.

GRAY, W. W., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Barrancas, Florida, and ordered for duty at Fort Columbus, New York Harbor.—*S. O. 147, Department of the East*, July 13, 1885.

EVESTE, EDWARD, *First Lieutenant and Assistant Surgeon.*—Ordered for duty as Post Surgeon, Fort McDermit, Nevada.—*S. O. 68, Department of California*, July 11, 1885.

POLHEMUS, A. S., *First Lieutenant and Assistant Surgeon.*—Ordered for duty as Post Surgeon, Benicia Barracks, California.—*S. O. 68, Department of California*, July 11, 1885.

WINNE. C. K., *Captain and Assistant Surgeon.*—Ordered for duty at Benicia Arsenal, California.—*S. O. 68, Department of California*, July 11, 1885.

EDIE, G. L., and BLACK, C. S., *First Lieutenants and Assistant Surgeons.*—Ordered for duty with troops en route to Department of Missouri.—*S. O. 78, Department of Texas*, July 10, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL DEPARTMENT OF THE U. S. NAVY, DURING THE WEEK ENDING JULY 18, 1885.

OWENS, THOMAS, *Assistant Surgeon.*—Granted sick leave for one month, July 14, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

ORIGINAL LECTURES.

PLEURITIS HÆMORRHAGICA TUBERCULOSA WITH PURPURA HÆMORRHAGICA.

A Clinical Lecture, delivered at the General Hospital, Vienna.

BY PROF. HERMANN NOTHNAGEL.

(Reported by J. P. CROZER GRIFFITH, M.D., of Philadelphia.)

GENTLEMEN: The patient [who has been previously questioned before the class] complains of shortness of breath, weakness, and cough accompanied by expectoration. He says he feels tired and languid,and, as you notice, he is so very hoarse that he is almost unable to speak. We will now hear the clinical history.

"The patient is a baker, aged twenty-one years. His father died of some lung affection, but with this exception his family history is good. For several years past he has had a cough, which has been gradually getting worse, and which is accompanied by a little mucous expectoration. Five weeks ago he became very hoarse and short of breath, but he had no chill. He found, too, that he was unable to lie on his right side, and his appetite became bad. He declares that he has never spit blood."

Now we must remember that both bakers and millers are very liable to suffer from cough induced by the dust which they inhale. This may finally lead on to bronchial catarrh, and even to tuberculosis.

Proceeding to the examination of the case before us, we find the mental faculties unaffected, and that there is no headache, but we notice a high degree of pallor of the face. The gums and conjunctivæ are pale; the lips pale and cyanotic. The bony framework is of moderate strength, and the muscular system tolerably well developed. The hands and arms are pale, and on the latter we notice an eruption of acne, and, in addition to this, a number of small subdermal hemorrhages. The pulse beats 120 in the minute, is soft, moderately full, and with tension below normal. The frequency of the respiration is 46 per minute. On the legs there is no dropsy, but we observe a great number of the same small hemorrhages. The same is true of the thighs. Larger suggillations in the muscles can nowhere be found. The skin on the trunk is pale and dry, and we see that the patient has fever. His temperature this morning was 100 5° F.; the maximum it has reached at any time is 103.1° F. What then is the chief thing we notice? A high grade of pallor. Yet in spite of this we find a well-developed panniculus adiposus and muscular system.

Now, in inanition and the attending anæmia there occurs a wasting of both muscular and adipose tissue. Whenever we have extreme anæmia without emaciation, the cause must be either: 1. A direct loss of blood; or, 2. A disease of the blood.

We will now examine the respiratory apparatus, to see whether we can there find any cause for the present condition. A laryngoscopical examination has already been made, and revealed only a general redness and swelling of the mucous membrane of the larynx. The thorax is of moderate length, broad, somewhat shallow, but well developed. The respiratory movement is not alike on the two sides; on the contrary, we observe that on the left it is much greater than on the right.

Upon percussion in the *mammillary line* we find the sound in the supraclavicular fossa on the right side somewhat deeper than on the left; over the clavicle alike on both sides; in the right infraclavicular fossa again deeper and louder. In the second intercostal space, left, we get a normal tone, right, a deeper, louder, and fuller one. Now, completing the percussion in the mammillary line left, we find the sounds everywhere normal. On the right side, however, in the third intercostal space, the note is abnormally deep; over the third rib we get a dulness; and as we percuss downwards we find this continuous and increasing.

In the *axillary line* the right side exhibits a marked dulness from the axilla downwards, while the left gives a normal sound. Posteriorly, in the left suprascapular region, the sound is normal; in the right it is louder and fuller. In the interscapular region, and elsewhere over the posterior portion of the chest, the right side is everywhere duller than the left.

What have we now ascertained?

1st. That there is a dulness over the right side, beginning anteriorly at the third rib, and posteriorly at the upper part of the interscapular space.

2d. That this dulness increases in intensity as we percuss downwards.

3d. That there is an abnormally loud and deep percussion note over the upper portion of the affected side. This last is due to the increased tension of the lung, and all together indicate the existence of a pleuritic effusion.

Proceeding now with auscultation, we find everywhere on the left side puerile respiration. On the right side, as far as the second intercostal space, the respiration is weak and vesicular, but with prolonged expiration. In the third intercostal space it is bronchial, but soft, and is accompanied by fine mucous râles, and below this point it continues soft, weak, and bronchial. Thus the auscultatory signs also indicate an effusion into the pleural cavity, and there is, in fact, no doubt that this exists. But we must again consider the pallor, for we have seen together up to to-day but one other case of pleuritic effusion so pale. That was, you remember, a patient with empyema, who was, moreover, much emaciated. What is here the nature of the effusion, and what causes the pallor? We will examine the rest of the body, in the hope of finding there some cause.

The tongue trembles when it is protruded. It is damp and not coated. The heart's impulse is weak, and the apex-beat to be felt most distinctly in the fifth intercostal space in the mammary line. This shows

Digitized by Google

that it has been displaced by the effusion somewhat towards the left. The valvular sounds are clear, and no murmurs or *bruit de diable* are to be heard in either the heart or vessels. The abdomen is soft and its percussion sounds normal. The liver is slightly displaced by the pressure of the fluid in the pleural cavity. The spleen cannot be felt, nor does percussion show it to be enlarged, and we cannot, therefore, entertain the thought of leucæmia. The urine is lessened in quantity; its specific gravity is 1026, and its color yellow. We test it and find it intensely acid. You see the sediment in it, which is composed of urates, and you see also, as I test it, that it contains no albumen, in spite of the presence of fever. The stools are normal in frequency and quality. Have we now found a cause for the pallor? Not yet; and we must look at the blood. [Examines a drop under the microscope.] The white blood-corpuscles are but slightly increased in number, and the red are altered neither in quantity nor quality. Therefore, from this source we learn nothing. There is now but one method left us, and that is to examine the effused fluid. First let us consider certain points in differential diagnosis.

When a patient with a pleuritic effusion has no fever, the fluid is, as a rule, serous. When, however, long-continued fever is present, it consists generally of either pus or blood. But we may have blood or pus in the pleural cavity, and no fever, as occurs in the case of the hemorrhagic effusion accompanying carcinoma of the pleura; and we can also have a clear serous fluid and yet fever may be present. So we see that from the temperature alone we cannot diagnosticate the nature of the fluid.

Great stress is laid by some authorities on the fact that when we find, in addition to the pleuritic effusion, evidences of carcinoma, tuberculosis, or scorbutus, the exudate is probably hemorrhagic. By some, too, the color of the skin is considered an important diagnostic sign. Namely, that when a patient with a pleuritic effusion has exhibited a rapid paling of the skin, the fluid consists of either pus or blood.

Others claim that the presence of œdema of the skin is a sign that the exudate is purulent. This œdema can occur, of course, in numerous diseases, such as abscesses, diseases of the kidneys, etc.

Two questions arise here: First, can œdema be absent in cases of purulent effusion; and, second, can œdema accompany ordinary serous effusion? And the answer to both, it must be admitted, is, "Yes, under certain conditions."

Then importance is given by some to the alteration of the voice, namely, that the presence of a hoarse, hollow voice, such as we hear in this case, indicates that the fluid is probably purulent.

Some of these different diagnostic signs are not without weight, and we conclude that when in any case of pleuritic effusion we have unmistakable evidences of carcinoma, tuberculosis, or scorbutus, a rapid paling of the surface of the body, and œdema of the skin, the exudate is probably, but not necessarily, either purulent or hemorrhagic.

We will now try the "puncture test" with the hypodermatic syringe, and settle the matter finally. You see that the fluid consists of blood; that is, we have a hemorrhagic effusion. Now we know why the patient is so pale. There is probably a large quantity of blood in the pleural cavity.

Our next question is: "Why is the exudate bloody?" A hemorrhagic pleuritic effusion can occur in an otherwise healthy person as the result of *trauma*. When no such cause exists it is usually due to either

1. Tuberculosis.
2. Carcinoma or sarcoma.
3. Diseases of the hemorrhagic diathesis, as:

(*a*) Scorbutus,
(*b*) Purpura hæmorrhagica,
(*c*) Hæmatophilia,
(*d*) Pernicious anæmia,
(*e*) Icterus.

Which is it in this case?

The patient has no signs of tuberculosis in the left lung. In the upper portion of the right lung we hear some moist crackling râles, but these are a common accompaniment of pleuritic effusion. Indeed, under the existing conditions, it is exceedingly difficult to determine whether or not tuberculosis be present. The sputum is muco-purulent, contains but little blood, and is slightly putrid. Microscopical examination has discovered no tubercle bacilli.

You notice the purple spots in the skin of the arms and legs. These slight hemorrhages are characteristic of purpura hæmorrhagica. Their nature indicates that they are not due to scorbutus, for they are not large enough, and there are, moreover, no accompanying hemorrhages into the muscles. When you have but a single isolated case, and no previous history to indicate that it is probably that disease, you cannot be justified in diagnosticating scorbutus unless you find the affection of the gums. Look at them in this case. You see none of the characteristic swelling and ulceration seen in that disorder.

The patient has no tendency to bleed from other parts of the body; therefore, hæmatophilia is out of the question, So also are icterus and pernicious anæmia. There remain to us, therefore, as possible causes of the hemorrhagic effusion, carcinoma or sarcoma of the pleura, and purpura hæmorrhagica. Sarcoma or carcinoma are probably not present. Primary carcinoma of the pleura occurs but seldom, and then, too, the patient would be emaciated as well as pale. Therefore, taking everything into consideration, we think that the patient is suffering from purpura hæmorrhagica, and that this has predisposed to the hemorrhage into the pleural cavity. The prognosis is, of course, unfavorable.

In regard to the therapeutics, Would you aspirate in this case? No; only when the effusion becomes so great that aspiration is a necessity. *Do not give iron.* You must never give iron to a patient with fever; and the same rule applies to cod-liver oil. All we can do here is to employ cold externally, and to administer nourishing food and stimulants.

POSTSCRIPT (three days later).—I have just attended the autopsy of the patient we had before us three days ago. You remember that the left lung showed no signs of disease, and that the presence of fluid in the right pleural cavity rendered it impossible to ascertain whether or not the lung of this side was affected. The sputum, moreover, contained no tubercle bacilli. We, therefore, concluded finally that the disease was one of the disorders of the hemorrhagic diathesis, viz., pur-

Digitized by Google

pura hæmorrhagica, as proved by the small hemorrhages in the skin.

The autopsy confirmed this, but revealed also another disorder in addition to it. We found an old and healed tuberculosis of the lungs, and, arising from this source, an acute miliary tuberculosis of the pleura, producing the hemorrhagic effusion. The pleura was covered with miliary tubercles and fibrin, and its cavity filled with dark red clots. The left lung exhibited some old cicatrices, and the right several similar but smaller ones. This condition could not, of course, have been detected during the life of the patient. Our revised diagnosis must be, then, "pleuritis hæmorrhagica tuberculosa."

In the ileum we found two small tubercular ulcers with extensive ecchymotic surroundings—another example of the tendency to hemorrhage.

This case is an unusual one, in that the acute eruption of tubercles was almost purely local. It is also of very rare occurrence that without any affection of the lung we find such a large hemorrhage into the pleural cavity.

ORIGINAL ARTICLES.

TWO OVARIOTOMIES IN THE SAME PATIENT.[1]

BY JOSEPH RANSOHOFF, M.D., F.R.C.S. ENG.,
PROFESSOR OF DESCRIPTIVE ANATOMY AND CLINICAL SURGERY IN THE MEDICAL COLLEGE OF OHIO.

THE kindness of Prof. Schœnborn, of Kœnigsberg, permits me to lay before you the complete clinical history of a patient upon whom laparotomy was twice performed for ovarian disease. The first operation was made by Schœnborn in 1880, the second by myself in 1884.

M. A., aged 24, married, was admitted into the surgical clinic of Kœnigsberg, July 7, 1880. Her father died of some pulmonary affection. Mother and two younger sisters living and in good health. Two sisters and a brother died in childhood from causes unknown to the patient. Until her marriage, five years ago, the patient was in perfect health. Soon after marriage irregularities of menstruation supervened. The menstrual flow would appear at intervals of eight to ten days and continue for a like period. Three and half years after her marriage, the menses disappeared for seven weeks, when, after reappearing irregularly for a short time, they ceased entirely. During the last four years the patient has been conscious of an unpleasant sensation in her abdomen, but until lately has not suffered any pain. Eighteen months ago she discovered an abdominal tumor which has gradually increased in size. In the last few months the pain has been of sufficient severity to confine her to bed for a week at a time. Patient has never been pregnant.

Status præsens: Patient presents a robust appearance and is well nourished. Thoracic organs normal. The abdomen is distended by a uniform swelling which extends further towards the right side than the left. The integument is somewhat taut; linea alba not pigmented. The greatest measurement of the abdomen is two inches below the umbilicus, where the girth measures thirty-six and a half inches. Other measurements of the abdomen are: eight and a half inches from umbilicus to anterior superior spinous process; eight and a half inches from the symphysis pubis to the umbilicus, and seven inches from the latter to the ensiform cartilage. Palpation reveals the presence of a firm and slightly uneven tumor, on the left aspect of which a number of prominences can be felt. Immediately above the symphysis a small portion of it can be grasped by the hand and moved from side to side on the rest of the growth. Vaginal examination does not reveal the presence of a growth. In a bimanual exploration the fingers can be felt moving upon each other, the flattened cervix uteri intervening between them. The sound enters the cervix readily, but can be pushed into the body only by greatly depressing the handle of the instrument.

Diagnosis: Abdominal tumor.

The operation, July 28, 1880, was made under a spray of salicylic acid. After the surface of the abdomen had been thoroughly cleansed, an incision was made in the linea alba from above the umbilicus to the symphysis. After the hemorrhage was checked, the peritoneum was divided on a grooved director. The smooth surface of the tumor, presenting a number of very large veins, was thus exposed, and the absence of adhesions was established by the introduction of the hand. The tumor sprang from the right ovary. Since fluctuation could not be detected at any part, the use of the trocar was dispensed with and the tumor drawn through the wound and its pedicle was caught in a clamp. After the tumor was cut away, the pedicle was tied with silk ligatures and returned to the abdominal cavity. It was now observed that the left ovary was somewhat enlarged. The toilette of the peritoneum having been completed, a drainage-tube was inserted into the lower angle of the wound. This was closed by six quilled sutures which included the peritoneum and twenty superficial sutures. Lister dressing.

29th.—Patient complains of pain in the abdomen for which ten drops of tinct. opii were given. Catheterization resorted to.

30th.—Vomited twice during the night and repeatedly during the day. Pain in abdomen increased. Hypodermic injection of morphia at night.

31st—Vomited once during the night. Pain continues unabated. Treatment continued.

August 2.—Vomiting has ceased and pain diminished. To the left of the wound, the abdomen is quite sensitive to pressure. Pulse 128, temperature 104.6°. The drainage-tube which, contained an admixture of blood and pus, was withdrawn. All the deep and seven superficial sutures were removed. The Lister dressing was reapplied and treatment was continued.

6th.—The dressing was changed and the remaining sutures were removed. The wound gapes in its upper and middle thirds, and a considerable quantity of pus escapes through the punctures made by the needle. The margins of the wound are approximated by strips of adhesive plaster. The Lister dressing is substi-

[1] Read before the Section in Surgery, American Medical Association, April 29, 1885.

tuted by one of cotton batting. From this date the condition of the patient gradually improved, and she was discharged from the hospital on the 8th of September, cured. The following is the anatomical description of the tumor as given by Prof. Baumgarten. "The tumor, somewhat larger than an adult head, is globular in shape. Its surface is smooth, and on one side the normal tube is attached. A section reveals it to be an almost solid mass from which, as from an opened honeycomb, there oozes from innumerable orifices a thick grayish-white secretion. Microscopic examination shows that the tumor consists of cysts, for the most part microscopic in size, the walls of which are covered by a single layer of cylindrical epithelium and are filled by mucoid masses."

About two months after the patient left the hospital at Kœnigsberg, she began to menstruate, and there has been no interruption to the catamenial flow since. In 1881 she came to this country, and remained well until the summer of '84. In the spring of the previous year she discovered a distinct abdominal swelling which slowly increased in size. From time to time severe abdominal pains, associated with febrile attacks, supervened, for which the patient sought relief in bed. While these attacks lasted, the patient suffered greatly from vesical and rectal tenesmus. When I saw the patient in October, 1884, she presented the following condition: "Rather robust woman, apparently in fair health. Examination of the thoracic viscera gives negative results. The abdomen presents evidences of the first laparotomy. Over a surface two inches in width and extending from a point three inches below the ensiform cartilage to the pubic symphysis, the abdominal wall is greatly attenuated, and has the appearance of cicatricial tissue. Two inches above the pubes a firm ovoid body an inch in width and of somewhat greater length is felt to be loosely attached to the cicatrix. Through the latter the smooth surface of a tumor is readily recognized, and the absence of adhesions established. The tumor is central, and the abdomen presents a 'dome-like' appearance. Its measurement a little below the umbilicus is forty-two inches. Percussion of the abdomen yields a dull note except in the epigastric and lumbar regions, where the intestinal percussion sound is elicited. On deep palpation an indistinct sense of fluctuation is experienced. Vaginal examination shows the cervix high up and almost out of reach. In the posterior cul-de sac, more pronounced on the left, the vaginal wall is bulged downwards by an elastic swelling which is unconnected with the uterus, and by bimanual examination is shown to be a part of the abdominal tumor. By greatly depressing its handle the sound can be introduced into the uterus about two inches." In view of the history of the case, and the physical signs presented, the diagnosis of multilocular ovarian cyst with extensive pelvic adhesions was made, and an operation advised. This was performed Nov. 19th, one week after the cessation of a menstrual period. Drs. Palmer, Krouse, Wilder, and McKee were present, and rendered most valuable assistance.

Owing to the great width of the cicatrix, the incision was made in the median line from a point two inches below the umbilicus to a point equally distant from the symphysis This incision was a little over four inches in length, and was attended by very little hemorrhage. When the peritoneum was divided the anterior surface of the tumor was exposed to view and presented the typical grayish color and glistening appearance of the multilocular cyst. The hand being introduced into the abdomen, the absence of anterior and lateral parietal adhesions was established. The tapping of the cyst was followed by the escape of a pailful of thick ropy chocolate-colored substance, but to permit the withdrawal of the tumor it was necessary to enlarge the incision. When the pedicle was looked for, none could be found. The floor of the sac was so firmly adherent to the rectum, the body of the uterus and left side of the abdominal wall above the latter that a separation of these adhesions was wholly out of the range of possibility. No trace of the pedicle of the right ovary was discoverable. The peritoneal surface of the anterior abdominal wall from the umbilicus downwards had lost its glistening appearance, appearing roughened and mammillated. In view of the extensive pelvic attachments, it was decided to sew a portion of the cyst into the abdominal wound.

After thoroughly cleansing the peritoneal cavity, the basal portion of the cyst was fixed in the lower three inches of the wound by ten silver wire sutures, which were made to include an inch of parietal and cyst wall, and by a like number of superficial sutures of catgut. The extruded portion of the tumor was then removed with the thermo-cautery, and the upper portion of the abdominal wound closed. To prevent the formation of a fistula from the small part of the cyst retained, its surface was everywhere touched with the thermo-cautery. A glass drainage-tube being then inserted, and the wound covered with boracic acid, an iodoform gauze dressing was applied. Time of operation, fifty minutes.

The patient rallied from the ether without vomiting, and in the evening the temperature was normal, and pulse 96. A hypodermic injection of morphia was administered.

Nov. 20.—During the night severe pain in the abdomen supervened. The dressing is saturated with a fluid similar to the contents of the cyst. No point of tenderness. Morning temperature 100.6°; evening temperature 101.6°; pulse 120.

21st.—Passed a fair night under the influence of an anodyne. Has taken considerable milk and champagne. Abdomen very much distended and tympanitic, but not tender. Morning temperature 101.5°; evening temperature 104°. Dressing changed and peritoneal cavity washed out with a saturated solution of boracic acid.

22d.—Patient complains of an intense desire to evacuate the bowels. Is menstruating. When the dressing was removed, it was noticed that the discharge was becoming purulent, and that large shreds of gangrenous tissue were separating from the retained portion of the cyst wall. Tympanitic distention unchanged. Morning temperature 101°; evening temperature 105.5°.

23d.—Menstruation continues. The dressing is saturated with a profuse purulent discharge. Drain-

Digitized by Google

age-tube temporarily removed and large sloughs removed from the wound by irrigation. Morning temperature 100°; evening temperature 100.5°.

25th.—The abdomen is still distended, and patient complains of some pain. Condition of the wound improved. The sloughs have all become detached, and the wound is covered with healthy granulations. Morning temperature 99°; evening temperature 99.5°.

27th.—Menstruation has ceased. A copious evacuation of the bowels followed the administration of an enema.

From this time forward the patient gradually improved for two weeks when a rise in temperature, an increased pulse-rate and marked pain supervened. On examination of the abdomen an indistinct induration to the left of the wound was discovered. On the 14th of December, fluctuation was quite apparent, and twelve ounces of creamy pus were removed with an aspirator. The benefit derived from this was temporary. Reaccumulation of pus in quantity sufficient to be felt by vaginal examination took place, for the relief of which a free incision was made through the abdominal wound. From this time on, the patient rapidly recovered, and was discharged from the hospital ten weeks after the operation. The wound has now been completely closed for three months, and the patient is enabled to perform ordinary household duties. Since the operation the catamenial flow has appeared four times, each period lasting from three to five days.

This case, which I have taken the liberty to present, opens for discussion three questions of considerable importance. They are the comparative frequency of cystic disease in both ovaries, the advisability of performing double ovariotomy when the disease in one gland is but little developed, and the method of treating the cyst by suture to the abdominal wall after more or less of it has been excised.

The observations of Scanzoni based on post-mortem examinations, that in fifty per cent. of cases both ovaries are affected, is not verified by the clinical experience of most operators. In 366 operations for the removal of ovarian growths witnessed by Dorsan, the tumor involved both ovaries in 48, and in 20 other cases, "suspiciously enlarged" ovaries were removed after the tumor had been cut away. Thus in 18 per cent. of his cases both ovaries were affected. In 132 ovariotomies Goodell found it necessary to remove both ovaries in 50 per cent. of all cases. In 293, 101, 229, and 56, and 1000 operations made respectively by Koeberlé, Tait, Keith, Olshausen and Spencer Wells, double ovariotomy was necessary in 37, 27, 13, 9 and 82. While according to the experience of Wells both ovaries must be removed in 8 per cent. of all cases, according to that of others double ovariotomy is indicated in 16 per cent. of all cases. An examination of these statistics likewise shows that different operators are far from agreed as to what constitutes sufficient disease in the second ovary to call for its removal. It must be remembered, in this connection, that the removal of the second ovary adds very much to the danger of the operation. While from single ovariotomies, Wells and Koeberle show a mortality of 22 per cent., the former in 82 double ovariotomies has lost 34 per cent., whereas, 51 per cent. of those operated on by Koeberlé for bilateral ovarian disease have died.

In view of these facts, and the youth and conjugal relations of many of these patients, a question as to the propriety of removing both ovaries at one operation may be raised. Unless the less diseased gland be the seat of quite marked multilocular cystic degeneration, it would probaby be better in many cases to leave it undisturbed, or to empty the cysts of their contents. This was practised by Wells in a girl of 19, from whom he had removed the right ovary. "The left ovary was enlarged to nearly double the normal size. Two follicles, about the size of cherries, were distended by clot. These I laid open, turning out their contents. It seemed hard to unsex a girl of 19, and, if the disease should progress, a second ovariotomy could still be done. This operation was performed in November, 1864. After her marriage the patient gave birth to four children, and when last heard from, in 1881, she continued in good health." The certainty of sterilizing a woman by double ovariotomy should make us hesitate to perform it on young persons. In thirty-two cases which I was enabled to collect in which the operation was twice performed on the same patient, children were borne by five of the cases. The aggregate number of children born between the two operations was fourteen. In one of Atlee's cases the patient was delivered of a child, although the interval between the two operations was only sixteen months.

Another important factor that should incline the operator to conservatism in dealing with a slightly diseased second ovary is the small mortality attending second ovariotomies. Of thirty-two cases, only five, or 15 6 per cent., terminated fatally. If the case of Mears, which died two months after the second operation from an independent affection of the liver, be excluded from the fatal cases the mortality from second ovariotomies is reduced to 12.5 cent. In view, therefore, of the greater danger of double ovariotomy, and the lesser mortality of the second operations, it seems plain that the former procedure should be refrained from except in women approaching the climacteric, and unless the disease in the second ovary be quite pronounced.

From an examination of the subjoined table a rather satisfactory idea of the rapidity with which disease develops in the remaining ovary is obtained. Of thirty cases in which the interval between the two operations is noted, the disease reappeared in the second ovary to an extent sufficient to warrant a second operation, fourteen times in less than five years, and sixteen times after the lapse of that period. In seven cases a second operation became necessary in less than two years, and in three cases in less than a year. On the other hand, in six cases an interval of ten years or more existed between the two operations. In four of the recorded cases menstruation continued after the second operation.

The method of treating the cyst by sewing the small part which could not be removed into the abdominal wound is the feature of greatest practical importance in the case presented. It is almost needless to observe that this plan was adopted through necessity, and not through choice. A separation of

the pelvic adhesions would have involved the integrity of the uterus, ureter, and rectum, and would, with little doubt, have been followed by a speedily fatal issue. It is remarkable, therefore, that while this substitute for ovariotomy has been performed a considerable number of times, and is recommended by Mueller, Schroeder, Pernice, and Rheinstaedter, English and American writers have given it little or no consideration. Of incomplete operations, it is manifestly the most perfect that can be devised, being particularly adapted to cases of broad pelvic adhesions. By closely uniting the remaining portion of the cyst-wall to the lower part of the abdominal wound, the drainage of the peritoneal cavity is not interfered with, and the lining membrane of the cyst-wall is treated extraperitoneally. The most potent arguments against the procedure, for which I would venture to suggest the term "ventro-cystorrhaphy," to distinguish it from other incomplete operations, are, that there is danger of recurrence of the disease, or that the profuseness of the discharge or its long continuance leads to a fatal exhaustion. While experience has shown that these results sometimes follow, it appears to me that they can generally be averted by freely incising the secondary cysts which remain, and by destroying their secreting surfaces by the free use of the thermo-cautery; thereby the cyst-wall will be speedily converted into a healthy granulating wound, which cicatrizes with the rapidity and permanence of ordinary wounds.

ON THE VALUE OF A PROPER RESPIRATORY DIET IN PHTHISIS.

BY SOLOMON SOLIS COHEN, A.M., M.D.,

CHIEF CLINICAL ASSISTANT, OUT-PATIENT MEDICAL DEPARTMENT, JEFFERSON MEDICAL COLLEGE HOSPITAL, PHILADELPHIA.

AMID the conflicting views entertained upon questions connected with the etiology and pathology of phthisis, two facts concerning the disease stand prominently forth, attested by universal experience.

The first is that the disease, or group of diseases, known as pulmonary consumption, is clinically preeminently characterized by failure of nutrition; and the second follows almost as a corollary, that those measures which tend to conserve and restore nutrition, give the best results in the therapeutic management of the disease.

The importance of good food, proper exercise, and fresh air, is not to be announced at this date as a new discovery; nor are the benefits to be derived from those agents of the materia medica variously classed as corroborants, tonics, promoters of constructive metamorphosis, matters of dispute or discussion.

It is not the purpose of the present article to review in detail the various plans of treatment proposed and in vogue, nor to discuss the comparative merits of different drugs in meeting certain indications. The writer desires to call prominent attention to a single feature in the management of cases of consumption, the importance of which is theoretically admitted by all, but which is practically too often neglected; namely, the furnishing of a proper respiratory diet.

That a due supply of oxygen is essential to maintenance of nutrition, is a fact so trite that it hardly seems to deserve especial mention; yet we rarely find the provision of this all-important agent made that decided feature of a plan of therapeusis which a knowledge of its necessity should dictate. It is true that consumptive patients are, in a general way, told to "keep out of doors as much as possible whenever the weather permits"—and that many are sent to various so-called health resorts, in the hope that a milder climate will permit more frequent open-air exercise, or that some peculiar quality in the atmosphere of the chosen place—varying with the theories or prejudices of the physician—will exert a beneficial influence upon the progress of the case. But setting aside the again conflicting theories and assertions as to what constitutes the most desirable climate for the phthisical, the fact remains that those who can avail themselves of change of residence constitute but a small proportion of the number of sufferers. How can we supply respiratory pabulum to those who are compelled to stay at home, where the weather does not permit the requisite amount of life in the open air; to those who are too feeble, or whose avocations are too confining, to allow them to avail themselves of the opportunities afforded by fine weather?

The inhalation of oxygen has been proposed as a measure theoretically indicated to favor nutritive processes in the consumptive. I have had no personal experience with this plan of treatment, having been deterred from resorting to it by the adverse dictum of J. Solis Cohen,[1] who found but a temporary benefit to result from its employment; followed, as Fourcroy had previously recognized by a more precipitate decline.

The inhalation of air subjected to compression, a procedure most prominently advocated by Waldenburg[2] is, however, a means of therapeusis in consumption, not properly appreciated, at least in the United States. The effect is twofold, mechanical and chemical; but the greater value is probably attributable to the former. That an increased quantity of oxygen is supplied with the increase of pressure is of course self-evident, but of what avail would this alone be when the quantity of oxygen supplied under ordinary pressure far exceeds the amount utilized by the normal lung? It is not the quantity of oxygen supplied, but the quantity of blood exposed to oxygenation, to which attention must be directed. Entering the lungs under pressure, however, the air is capable, mechanically, of producing several very desirable effects.

One of the most notable features of the respiratory act in consumptive patients, is the deficient expansion of the chest. Whether this be due to actual consolidation of pulmonary structures, or simply to muscular weakness, it prevents the due interchange of gases so essential to normal respiration, and limits the area of blood exposed to the atmosphere. No matter how balmy the climate, nor how fair the day, a patient with insufficient capacity of expansion

[1] Inhalation; its Therapeutics and Practice, Second Edition, Philadelphia, 1876, p. 77.

[2] Die Pneumatische Behandlung der Respirations und Circulations Krankheiten, Berlin, 1875.

Digitized by Google

must, out of doors as well as indoors, not only fail to inhale a due supply of oxygen, but also fail to exhale the waste products of respiration. Where strength is not too far gone this may be in a measure overcome by voluntary forced respiration; but with the majority of patients some extraneous force must be invoked. This is readily found in the expansile power of compressed air, which forces its way into disused alveoli, and gradually increases the respiratory capacity. That the increase in chest measurement caused by inhalations of compressed air is due to increased expansion and to the forcing open of disused air-cells, and not to the production of an emphysematous condition, is proved by the fact that it is an actual increase in vital capacity. The act of expiration is perfectly performed, the tidal air is fully expelled, and the capacity for forced expulsion of the reserve air is retained.

Auscultation reveals the presence of the respiratory murmur in localities where it had not been previously manifested. I have frequently observed the progress of this reopening of disfunctionated alveoli. At first, the respiratory murmur in the disused areas is fitfully present towards the close of the administration. Inspiration in these situations is often accompanied by a peculiar intermittent râle, which simulates very closely the crepitant râle of the first stage of lobar pneumonia, but is rougher and larger; as if the current of inspired air made interrupted pressure against the agglutinated surfaces of the infundibuli. Gradually the râle disappears, the vesicular murmur becomes clearer, and is heard from the beginning of the inhalation, to some time after its close; and by degrees becomes firmly reëstablished during voluntary respiration. The amount of increase in vital capacity attainable by the persistent and systematic inhalation of compressed air is almost incredible.

Domanski,[1] of Cracow, reports a case in which a gain of 250 cubic centimetres (2850-3100) was produced, and another in which 200 cubic centimetres (2100-2300) increase was obtained. Oertel[2] refers to still greater gains, even 1000 centimetres. In the case of an officer of the United States Navy, under the care of Dr. J. Solis Cohen and myself, the vital capacity was increased from 320 cubic inches to 345 cubic inches, by inhalations of air under a pressure of $\frac{1}{60}$ of an atmosphere, twice daily, for a period of two weeks; one of Waldenburg's cylinders being emptied three times at each visit. This patient was a man of tall stature (6 feet, 2 inches) and powerful build, with the signs of a limited area of consolidation at one apex. In a man 5 feet, 4 inches high, with signs of condensation over the whole of one lung, the vital capacity was increased from 135 to 155 cubic inches.

As to the exact mechanism of the production of this increase, I hesitate to speak positively. The results cited cannot be obtained in every case, even of incipient disease. The amount of space gained as represented by the extent of the area over which respiratory murmur is more or less completely restored, varies greatly. In no case, however, which has been deemed suitable for the treatment, have I failed to observe some improvement in the chest expansion, and in respiratory capacity; although some of these cases have been quite far advanced.

I am inclined to believe that the process of restoration is three-fold. There are, roughly speaking for the purpose of this argument, three classes of alveoli in the phthisical lung. First, the alveoli of healthy areas, which are not always fully expanded, owing to deficient tone in the respiratory muscles. Secondly, alveoli around which, or around the terminal bronchioles of which, a moderate degree of congestion and low grade inflammatory infiltration exists, encroaching, to a greater or less extent, upon their calibre; an impairment increasing as we approach the third class, namely, those occluded or obliterated by actual eruption, deposition, or infiltration of tubercle. Now the increased capacity of the first class is clearly attributable to improvement in muscular tone, resulting directly from the systematic gymnastics to which the thorax has been subjected, and increased indirectly by the general improvement in circulation and nutrition, which is the ultimate aim of the process. The increased capacity of the second group of air cells is partially due to the same cause, but the inference seems plausible, that the systematic compression of congested tissues and inflammatory products due to the dilation of the bronchioles and alveoli by the expansile power of compressed air, results in unloading of engorged vessels, and absorption of exuded and proliferated cells; in perfect analogy with the results of mechanical compression externally applied in many surgical cases. Whether any improvement whatever results in the condition of the third group of obliterated cells, namely, those in and around which tubercle has been developed, is a doubtful question.

But while the increase of respiratory capacity and the consequent improvement of nutrition, are the principal objects gained by inhalations of compressed air, they are not the only ones. When the treatment is first instituted the increase of cough and expectoration is marked. Retained secretions are stirred up and expelled from alveoli, bronchioles, and bronchiectasic cavities. Gradually as the air-cells and air-tubes become rid of accumulated and pent-up masses, the cough and expectoration diminish, the character of the expectorated material improves, and in favorable cases cough finally ceases. Thus the deleterious effect of the retention and decomposition of effete materials as well as the exhaustion consequent upon harassing and often ineffectual paroxysms of cough are obviated; resulting in still further gain of breathing space and in conservation of strength and nutrition. The beneficial effects of this increase in vital capacity can hardly be exaggerated. The mode of death in chronic phthisis, whether it be fibroid, catarrhal, or tubercular, whether the duration of the disease be protracted or comparatively short, clearly points to diminution of breathing space as the principal source of danger, and the establishment of so-called vicarious emphysema in cases of phthisis and chronic pneumonia is a therapeutic hint of Nature's, clearly indicating the

Digitized by Google

direction in which man's efforts should be directed. Increase of appetite is soon manifested, and if sufficient food of proper character and quality be provided, increase of weight rapidly results. In one case, that of a girl of eighteen years, referred to the Philadelphia Polyclinic by a physician of this city, a gain of eleven pounds was noted after six weeks of treatment. One of the most striking and earliest manifestations of improvement is the restoration of natural slumber.

The effects upon the circulation and upon the performance of the respiratory act itself, are of sufficient importance to warrant a separate study. They vary of course with the degree of pressure, the manner of administration, and the duration of the inhalations. Suffice it to say for present purposes, that while immediately after the ordinary administration, which consists of from ten to twenty-five or thirty inspirations of air under pressure varying from $\frac{1}{80}$ to $\frac{1}{30}$ of an atmosphere, the rapidity of the heart's action is always increased, and its force diminished, while the frequency of respiration is sometimes increased and sometimes lessened; after a few minutes rest, the depth of respiration and the power of the cardiac contractions will be augmented, while the frequency of respiration and pulse will be notably lessened. This process continuing, by degrees a permanent reduction is effected in the rate of pulse and of respiration, and the heart becomes permanently stronger. Thus, in the case last referred to, after two months treatment, respiration was reduced from 28 or 30 to 21; and the pulse from 104 to 88. I have never been able to obtain a constant series of results in regard to temperature; but coincidently with the reduction of the abnormal frequency of pulse and respiration, an abnormal temperature becomes lowered.

The advantages to be derived from "pneumatic treatment" are so great, and in many cases so striking, that any one who has once resorted to the method, will not fail constantly to increase his use of it; and it is difficult to refrain from writing so enthusiastically that the charge of extravagance or overstatement will not be brought. Of course, it is to be conjoined with proper dietetic, hygienic, and medicinal measures, according to the varying indications of different cases, and different stages in the same case. Of course, it is not equally applicable to every case, and may fail to fulfil all our expectations in instances apparently promising. Nevertheless there is no one agent capable of producing the same amount of good in the vast majority of cases of early phthisis or in chronic pneumonias and pleuro-pneumonias, which have not been of too long duration. That it has not met with more general introduction must be due to the expense of the apparatus hitherto devised, and the time which the administration of an inhalation occupies. It is hoped that both of these drawbacks will be, in a great measure, removed by the modification of the apparatus of Waldenburg, devised by the writer, and described in the *New York Medical Journal*, Oct. 18, 1884. This apparatus, essentially a small gasometer with a foot bellows attachment, can be procured at a moderate cost, and after the first few visits, can safely be entrusted to an intelligent nurse or patient, for home use.

PNEUMONOKONIOSIS.[1]

BY FREDERICK PETERSON, M.D.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF BUFFALO.

THERE are certain employments whose victims are confined to rooms in which the air is laden with dust of either an organic or inorganic nature.

There are the workers in coal and graphite mines whose lungs, by the inhalation of their dust, become miniature coal mines in the course of time. There are the laborers in iron and steel, such as file-makers, grinders, pin-pointers, cutlers, and needle-makers, the air respired by whom containing sharp, irregular, angular particles of iron, steel, silver, and emery—substances exceedingly difficult of removal. There are the workers in stone, clay, and glass, and in jewel-polishing, such as cement-makers, potters, glass-grinders, stone-cutters, lime-burners, plasterers, brick-makers, diamond-cutters, and masons. Then we have those whose employments lead them to breathe an air full of matters contributed by the vegetable kingdom, carpenters, chimney-sweeps, moulders, millers, cotton-carders, grain-shovellers, charcoal-burners, and workers in flax, hemp, and tobacco. Moreover, such occupations as brush-making, wool-cleaning, silk-carding, making feather ornaments, hair-picking, and button-making expose the operatives to the inspiration of various animal substances, some of exceedingly irritating nature.

In breathing the ordinary dusty atmosphere of cities, the quantity of dust inhaled is small, and it is easily removed by natural provisions in the lungs. But besides the dust of the streets in cities we have an enormous quantity of carbon poured into our urban atmospheres by locomotives, manufactories, and dwelling-houses.

There is for this reason more dust inhaled than can be removed by secretion, gravity, ciliary motion, and coughing. This excess of dust remains in the lungs. In looking at the epithelial cells lining the air-passages with a magnifying power of three or four hundred diameters, many of these are found to contain in their protoplasm dust-particles of various sizes and shapes. I always find dust cells in examining the sputum of hospital patients. The molecules have penetrated the cell walls, or perhaps have been *let in*, so to speak, by the cell itself. These particles now pass through the other side of the cell, or between cells, into the connective tissue containing the network of capillaries of the pulmonary, bronchial, and lymphatic systems. In the connective tissue are wandering cells and young connective-tissue cells, probably identical with white blood cells, which take up many of these foreign molecular matters and carry them about wherever they go. Large numbers of the particles of dust remain in the tissues, but more enter the lymphatic spaces and vessels which they completely fill, or are carried by their currents to the glands along the bronchi previously described. Here they lodge, these glands becoming the chief storehouses of inhaled dust. This is what becomes of the surplus of dust daily inhaled by every inhabitant of every city. Gradually the lungs become discolored

[1] Read before the Buffalo Microscopical Club.

Digitized by Google

by long lines and patches of black carbonaceous matter.

I have been interested for the past eighteen months in looking at the comparative amount of carbonaceous deposit in the lungs and mediastinal glands in over two hundred post-mortem examinations of persons of all ages from one month to eighty years. Up to two or three years there is no appreciable amount of dust deposited in the lung, but the imperceptible daily inhalations gradually, in the course of time, put their indelible black mark on every lung. In innumerable microscopic sections of lungs I have made, I never failed to find carbon deposits in the walls of the air vesicles and in the lymphatic spaces. In persons of seventy or eighty years of age, where senile atrophy has begun to lessen the size of the lungs, these organs are as a rule very dark, and often even entirely black. The bronchial glands are enlarged and like lumps of coal, where their natural color is white. If the lungs and glands show little discoloration at this time, it is because the person has lived a great part of his life in the country or at sea. Still it is probably very rare that this deposition of dust in the lungs of city people brings about serious disturbances. Undoubtedly, there is often a thickening of the walls of air vesicles, occasional faint local congestions, what might be termed in fact a slow, a fifty year chronic pneumonia which seldom gives any trouble. It is true that certain parts of delicate lungs irritated by dust might make a pleasant and fertile garden for the bacillus tuberculosis, or the smouldering chronic pneumonia might become a conflagration, an acute pneumonia, a phthisis, or a consumption. Perhaps, as some authorities state, this inhalation of dust may account, to a degree, for the death by consumption of twenty-five per cent. more people per thousand in cities than in the country.

Thus far, I have been speaking of the lungs of *all* dwellers in cities who suffer but to a moderate extent from pneumonokoniosis. Now let us turn to the operatives in the various dusty occupations I have mentioned. I will enumerate results in a few of them only. Some kinds of dust being more irritative than others, various degrees of chronic bronchitis, or bronchial catarrh, are brought about. The walls of the air passages and bronchial tubes thicken to an enormous extent, owing to a chronic pneumonia, in which new connective tissue is formed. Masses of stored-up dust may excite acute inflammations, followed by the formation of abscesses and cavities; in fact, a fatal phthisis is brought about. In the bronchial glands it is no uncommon thing for inflammation of a suppurative nature to take place. These glands may become so large as by pressure on a bronchus to offer serious mechanical interference to respiration. Coaldust does not seem to irritate as much as other substances, and though in coal-miners the lungs may be so filled with anthracite as to leave little trace to the naked eye of lung structure, yet the number of deaths from phthisis among them is less than one per cent. Here is a man of sixty-seven years, who may serve as an example: Not long ago, as an Erie County Post-mortem Examiner, I was sent by the Coroner to make an autopsy on the foreman of the "cleaning-room" of the large Jewett Stove Works in this city. He had died suddenly. The cause of death was fatty heart, but this fatty metamorphosis was due no doubt to the remarkable condition of the lungs. I make the following abstract from my record of the autopsy:

"On opening the thorax the lungs did not contract as usual. There were old and strong adhesions of both pleuræ everywhere. Both lungs were totally black over their whole surface. They were unusually hard and lobulated like a cirrhosed liver, only the nodules were larger. In numerous small patches there was great emphysema, some of the air-vesicles being the size of peas. Both lungs were very œdematous. The whole upper lobe of the right lung was one extremely hard tumor, like a fibroma, and perfectly black on cutting through. Upon touching with the hands the fresh-cut lung surface they become discolored, as if one were handling bone-black with wet fingers. The trachea, bronchi, and bronchial tubes had clean and white mucosæ. The bronchial and tracheal glands were much enlarged, very hard, and perfectly black throughout."

I visited the "cleaning-room" where he had been employed for thirty-one years and examined the dust under the microscope. In this room castings are brushed off, and the air is so dense with dust that it is almost irrespirable. The dust is chiefly charcoal from the moulds, but a little sand is mixed with it. A large force of men is employed in this room, and most suffer more or less with pulmonary difficulties.

Millers and carpenters suffer to the extent of ten per cent. from phthisis. Graphitosis pulmonum is not oftener followed by consumption than anthracosis pulmonum. I have some microscopic sections of lung from Silesian graphite-miners, prepared by me in Vienna. The men lived to a good old age, although there seems to be little lung-tissue amidst all this graphite.

It is among iron, steel, stone, and clay operatives that the most disastrous results are obtained. Flint-makers suffer to the enormous extent of eighty per cent. from phthisis, needle-polishers following with seventy per cent., and file-cutters with sixty-two per cent. It attacks only about forty per cent. of stone-cutters, although physicians meet with so many cases that they have given it the name of "stone-cutters' consumption." Grindstone-makers, sieve-makers, grinders, lithographers, cigar-makers, brush-makers, and glass-cutters average between 40 and 50 per cent. of deaths from phthisis. Gussenbauer has described a disease of the bones and marrow due to the inhalation of mother-of-pearl dust by button-makers. Among cotton-workers we have the form of consumption known to the profession as "cotton phthisis," the dust raised by beating being composed chiefly of silicious particles, cotton fibres, and woody matter; they all suffer more or less from the bronchitis, dyspnœa, etc., which are the phenomena of that form of pneumonokoniosis known as byssinosis pulmonum. Moulders suffer from anthracosis pulmonum, which frequently results in phthisis. They use exceedingly fine charcoal in their moulds when casting bronze, copper, and iron, which fills the atmosphere about them. Among potters the dust raised causes bronchitis and emphysema, the latter

Digitized by Google

being so common as to give rise to the name, "potters' asthma." There is a "grinders' asthma" known among cutlers, a form of consumption, and extremely fatal.

Particles of all these substances are found in the lungs with the microscope, though sometimes their recognition is not easy. It is occasionally difficult, for instance, to distinguish between the fine molecules of coal, iron, stone, and hæmatoidin, the red pigment of the blood. The lungs may be full of a dark pigment not due to inhalation at all. This is the slaty deposit of the Germans. It is found only in chronic pneumonitis, however, where there have been extravasations of blood, followed by decomposition of red blood globules in the tissues. The red pigment, or hæmatoidin, remains there permanently and changes into a brown or black color in time. Zenker relates the case of a woman who worked in a small room for many years with red sesquioxide of iron. At the post-mortem examination the lungs were found of a bright brick color, and upon analysis some 340 grains of iron were obtained.

Among hemp, silk, flax, wool, hair, brush-making, and cotton operatives, there is seldom any difficulty in recognizing their trades from a microscopical examination of parts of their lungs. Hirt made an autopsy on a maker of feather ornaments. The air-passages were found almost occluded by feathers and dust. Sometimes among charcoal-burners one finds pieces of charcoal sufficiently large to see a pore or two under the glass. Iron and steel particles may be distinguished by proper chemical tests, such as nitric acid and ferrocyanide of potash. The tests for silicic acid will often reveal the presence of stone or glass.

In American cities, where there is a large grain trade, and where are enormous elevators, as here in Buffalo, there is a form of pneumonokoniosis which results very seriously to laborers who do the shovelling. It has been called "grain-shovellers' phthisis." Prof. Rochester, of this city, has had numerous cases and has written an exhaustive paper upon the subject, describing what he calls "elevator pneumonia."[1] The chaff and sand are so irritating that an acute pneumonia is quite a common thing among these laborers. I had several cases while Resident Physician in the General Hospital some five years ago. This pneumonia is very apt to terminate in phthisis.

Thus far, we have been considering solely the inhalation of *irritating* particles, some having more tendency to excite disturbance than others; and we find that they cause almost always chronic bronchial catarrh, may cause emphysema, and often lead to pneumonia and phthisis. But there are occupations which force artisans to inhale not only *irritating* but *poisonous* substances. There is among tobacconists a form of dust-inhalation known as "tabacosis pulmonum," where we not only have some of the inflammatory effects described above, but also a variety of nervous disorders produced by the nicotine of the tobacco-dust. Some of the most deleterious of the trades are those where men are compelled to work in atmospheres impregnated with particles of arsenic, mercury, lead, and copper. Those who suffer most in these occupations are makers of artificial flowers, wall-papers, lead-miners and workers, hatters, painters, enamellers, type-founders, compositors, and coppersmiths. It is said that the hair and bones of coppersmiths become green from the absorption of acetate of copper. Type-founders, compositors, and others who work in lead, inhale sufficient to irritate the lungs and at the same time to produce often the serious colic and paralysis of lead poisoning. Hatters are exposed to arsenic and mercury poisoning, while those who make green wall paper and artificial leaves are apt to suffer from arsenic.

Though I have enumerated a large number of trades, in which the inhalation of various dusts, irritative and poisonous, lead as a rule to serious if not fatal results, the list is not complete. Compared with dust inhalation, other diseases produced by dust, such as certain eczemas and disorders of the eye, are unimportant. Therefore I have said nothing of them.

I have devoted a long paper to the inhalation of particles of organic and inorganic matter, and have spoken only of *dead* particles; but a much longer article might be written upon the inhalation of *living* particles, certain plants of lower orders, fungi, schizomycetes, etc., for I have no doubt that it is chiefly through inhalation that the various bacteria of scarlet fever, smallpox, yellow fever, tuberculosis, and so on through the catalogue of contagious and infectious diseases, reach the interior of our organisms.

I have some microscopic specimens of *pneumomycosis aspergillina* from human lung, showing one of the common forms of mould growing in a gangrenous cavity. Also some sections of tubercle from the lungs of rabbits which were made to inhale air passed through and over tubercular sputum. These sections I made under the direction of Prof. Weichselbaum, of the University of Graz, who has since published his experiments on *Inhalationstuberculose*.[1]

The disease-germs are present in the air of infected districts, are carried by the winds abroad, rise from countless sewers, cesspools, and marshes, and no doubt are inspired into the lungs by thousands at times; and very likely some enter the system by the alimentary canal, though this is by no means certain even in cholera.

To the passage of these living dust-particles the delicate walls of the air-vesicles can offer little resistance, when grosser coal, iron and glass molecules pierce them so readily.

MEDICAL PROGRESS.

COMMA-BACILLUS IN THE HUMAN MOUTH.—DR. W. D. MILLER, of Berlin, demonstrated, on February 16, at the Verein für Innere Medicin (*Independent Practitioner*, May, 1885), a comma-bacillus in the human mouth:

It is a well-known fact that comma-shaped bacilli are constantly present in the human mouth, even in a state

[1] Experimentelle Untersuchunge über Inhalationstuberculose in Wien. med. Jahrb., 1883, S. 169.

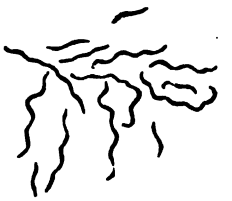
Digitized by Google

of perfect health. No particular importance was, however, attached to this fact until these bacilli were, by Prof. Lewis, asserted to be identical with Koch's comma-bacilli of Cholera Asiatica. Since that time very many bacteriologists have constantly endeavored to obtain the comma-bacilli of the mouth in pure culture. In the *Deutsche medicinische Wochenschrift*, 1884, Dr. Miller described two different schizomycetes which he had isolated from the oral secretions, and which in certain cases appeared as distinctly curved bacteria.

Not until lately, however, did he succeed in isolating from the mouth a true comma-bacillus, and it was finally accomplished, in two cases, by the use of coagulated beef-blood serum. The material from which the cultures were made was in each case found under the margin of inflamed gums in unhealthy mouths. Morphologically this bacillus is very similar to the other well-known comma-bacillus occurring as commata, either singly or in twos (S form), or in spirillum form (Fig. 1). In old cultures of gelatine all the commata

FIG. 1.

FIG. 2.



sometimes grow out into spirilli, giving a pure spirillum culture, cultivated on plates of beef-water peptone-gelatine at 20° C. They appear after twenty hours (in the second dilution), under a power of 100 diameters, as perfectly round, finely granular colonies, with a smooth border and brown color; in the same time the first dilution will be completely liquefied. They liquefy coagulated blood-serum with great energy, as do the other comma-bacilli. On the surface of Agar-Agar they form a yellowish coating, and convert the medium, superficially only, into a paste. They grow slowly on boiled potato. He has, consequently, not yet been able to establish any definite peculiarity of growth. The reactions of this bacillus are such as at once establish the fact that it is altogether a different organism from the comma-bacillus of Koch. It possesses, on the other hand, many of the peculiarities of the Finkler-Prior bacillus. Whether it is identical with this organism must be established by further experiment.

It must be remarked that this organism is, in all probability, not the one which is constantly to be found in every mouth. This grows rapidly on ten per cent. gelatine, while the latter appears to be unable to grow at all on the same medium.

Dr. Klein, in his report on Cholera Asiatica (*British Medical Journal*, February 7, 1885), states that the comma-bacilli of the human mouth have the same peculiarities of growth on gelatine with the comma-bacilli of Koch; but not one of the many forms of microörganisms, curved or otherwise, which Dr. Miller has obtained in pure culture from the human mouth, is for a moment to be mistaken for the bacillus of Koch. If Dr. Klein has really succeeded in proving by culture methods that the common comma-bacilli (vibriones) of the human mouth have the same reaction on gelatine as Koch's comma-bacillus, then it is very desirable that we should be told how he did it, it being the testimony of a very large number of bacteriologists that these organisms do not grow at all on gelatine. An exact proof that the vibriones of the mouth have, on various culture media, the same reaction as Koch's bacillus, would be a point of great weight, while a simple morphological similarity is of scarcely any consequence whatever.

In medical journals, particularly English journals, we continually meet with such statements as—"Comma-bacilli may be found in the human mouth;" "in the intestines in various disorders;" "in certain articles of diet," etc. Therefore, Koch's theory of the cause of Cholera Asiatica is entirely wrong. It is surprising that such views should ever be published by any journal. What if comma-bacilli are found in the human mouth? It is the testimony of ninety-nine out of one hundred that they are *not* the comma-bacilli of Koch. What if they may be found in stale cheese? The cheese spirilli have been proven to be altogether a different organism from Koch's bacillus. It matters not where comma-bacilli are found, or in how great numbers. The question to be decided is, whether any of these comma-bacilli are identical with Koch's, and the universal verdict is that they are not. It remains to be seen whether Dr. Klein can prove his statement as to the identity of the common mouth vibriones with the cholera bacillus.

To put down all comma-shaped microörganisms as one and the same, simply because they are curved, is no more reasonable than it would be to treat all bacilli in the same manner because they are straight, and to affirm that a particular bacillus cannot be the cause of tuberculosis, because bacilli are found in the human mouth, in the intestines, and in various articles of food.

VAGINAL HYSTERECTOMY FOR EPITHELIOMA.—At a recent meeting of the Société de Chirurgie de Paris, M. TILLOUX reported a case of vaginal hysterectomy for epithelioma, resulting in cure. Digital examination revealed the presence of an anfractuous cavity. The edges of the cervix uteri were eroded, but the culs-de-sac were intact. An extremely fetid discharge constantly escaped, and the general health was rapidly declining, as was evidenced by repeated attacks of syncope. The woman readily consented to operation, which was performed June 2, 1885. After chloroformization, the neck of the uterus was drawn down flush with the vulvar orifice. The first step of the operation was to incise the anterior cul-de-sac, and dissect away the uterus carefully from the bladder, a sound having been introduced therein to assist the operation. When the subperitoneal tissue was reached, the fingers only were used to separate the healthy from the diseased tissue. Incision of the posterior cul-de-sac was easily accomplished, and the peritoneum reached. In order to cut the two broad ligaments, M. Tillaux made use of his finger curved over the right ligament to draw it down, and also slipped over his finger, by the assistance of a Cooper needle, a silk ligature, which he knotted. For further security, a clamp was placed on the pedicle along the right border of the uterus, and the ligament was cut between the ligature and the clamp. The thread slipping at this juncture, it was necessary quickly to apply a clamp to

Digitized by Google

the utero-ovarian arteries. M. Tillaux then, seizing the uterus, which was now held only by the left broad ligament, drew it to the vulva, fundus forward, so as to stretch the ligament, which was thus tied and cut with ease. A point of suture were applied to the vaginal borders, a large drain introduced into the peritoneum, and the vagina packed with iodoform gauze.

The results of the operation, with the exception of slight nausea, which persisted for thirty-six hours, were uncomplicated, and the patient is at present entirely well.—*L' Union Médicale*, June 30, 1884.

PHYSIOLOGICAL AND THERAPEUTIC ACTION OF COCAINE.—DR. P. LIVIERATO, in *La Salute*, III., 1885, arrives at the following conclusions relative to the physiological and therapeutic effects of cocaine:

1. Cocaine, even in small doses, has a recognizable effect upon the peripheral nerves when subcutaneously injected.

2. Small doses (one-third of a grain) are able, in some instances, to diminish local sensibility, and to relieve local pain.

3. Larger doses (one and a half grains) may produce complete anæsthesia of all sensibility in a comparatively wide area.

4. Cocaine subcutaneously injected has, besides its local action, an effect upon the circulation.

5. Such action is manifested by doses of one-sixth of a grain, and much more plainly by doses ranging from two-thirds of a grain to a grain and one-half.

6. The frequency of the pulse is increased ordinarily in proportion to the size of the dose, by a few pulsations up to eight and even fourteen during the first minute.

7. The intra-arterial pressure is lowered in most cases from a few millimetres to twenty, according to the individual and independent of the dose.

8. The ascending sphygmographic curve under the action of the drug is lowered, and the descending curve becomes very short.

9. Respiration does not undergo any modification worthy of remark from the administration of doses ranging from one-sixth of a grain to one grain and a half of cocaine.

10. Its action in healthy individuals begins to be manifested within from three to five minutes after the injection, according to the dose. Its action may endure from twenty minutes to more than one hour.

11. Cocaine is capable of diminishing and removing all neuralgic pain.

12. Such effect is not only local, but is exercised at a point remote from that at which injection was practised.

13. The anæsthetic action commences a few minutes after the injection, and continues from one and a half to six hours, according to the dose.

14. Cocaine does not produce any general phenomena in doses ranging from one-sixth of a grain to a grain and a half.

15. The subcutaneous injection of the above doses does not produce mydriasis.—*Gazzetta degli Ospitali*, June 17, 1885.

LUPUS, A DISTINCT DISEASE FROM TUBERCULOSIS.—DR. PIETRO GAMBERINI, in a theoreto-clinical study upon lupus, concludes his observations by enumerating the following propositions:

1. Lupus is not identical with tuberculosis.

2. If tubercular tissue does really exist in the degenerations due to lupus, it is not proved that such tubercular material is the cause of the lupus—holding in mind the extreme scarcity of the bacilli found in lupus by various observers—while the opposite condition seems to exist in tuberculosis—*i. e.*, an abundance of bacilli.

3. The results of experiments made upon rabbits have no corresponding facts to which exception cannot be made in the case of human beings.

4. That the destruction observed in these animals points only to tuberculosis and not to lupus, from which it may be inferred that the latter is a distinct disease, but that accidental tuberculosis may be developed in it.

5. The incurability of the cutaneous tubercular ulcer, and the opposite condition generally observed in the ulcer of lupus, prove the greatest divergence in the morbid processes peculiar to each.

6. Points of differential diagnosis between the two diseases render it apparent that they are distinct, and possess their own pathological processes.—*Giornale Italiano delle Malattie Veneree e della Pelle*, March–April, 1885.

HAIRPIN RETAINED IN THE SIGMOID FLEXURE OF THE ILEUM FOR THREE YEARS: STERCORACEOUS FISTULA, AND CURE AFTER REMOVAL OF THE FOREIGN BODY.—DR. TH. WEISS reports in the *Rev. Médicale de l'Est*, No. 3, 1885, a case in which a hairpin was retained in the sigmoid flexure for a space of three years. The patient was a child, twelve years of age, whose health was seriously affected from an abdominal affection, the nature of which was entirely unsuspected. A few days subsequent to the first examination of the child, a fluctuating mass made its appearance in the left lumbar region immediately below the crest of the ileum. An incision was made at once, and was followed by the escape of a quantity of fetid pus, but examination failed to reveal the presence of a foreign body. After the operation, some amelioration of the child's condition resulted, but in a short time a second abscess formed in the region of the great trochanter, and evidently being in relation with the first. A second incision gave exit to a great quantity of unhealthy pus and permitted the introduction of a drainage-tube. After a few days, the pus which escaped at the lumbar incision was found to be mingled with feculent matter, which shortly became so abundant that anal defecation was almost entirely suppressed. At this time, erysipelas manifested itself, but soon disappeared under treatment, and soon after both the lumbar and crural wounds entirely cicatrized. After four months, however, the fistulæ were reëstablished, and fecal matter again escaped through them. At the end of a week they again entirely closed.

Two months subsequently, a third incision was necessitated by the appearance of a new fluctuating tumor. Finally, a month later, a fourth incision being necessitated for the introduction of a drain, a foreign body was discovered in the lumbar region at the level of the crest of the ilium. Some difficulty was experienced in seizing it with the forceps. Efforts to extract it were, however, successful, and it was found to be a large-sized hairpin, bent and rough with concretions.

Digitized by Google

Careful questioning elicited the information from the child that three years previously he had been in the habit of scratching himself with the hairpin on account of violent itching of the anus, and that on one occasion the pin suddenly escaped him, but that, as he experienced no discomfort therefrom, he had given the matter no attention.

In spite of a second attack of erysipelas, and continuous ill-health for so lengthy a period, the child completely recovered with the exception of a slight contraction of the left leg, which itself is apparently passing away by extension applied at night.—*Journal de Médecine de Paris*, May 31, 1885.

GARGLE FOR CHRONIC PHARYNGITIS.—BAMBERGER recommends the following gargle in chronic pharyngitis:

℞.—Ammonii chloridi . . . gr. lxxv.
Mellis rosæ . . . . ℥iss.
Aquæ . . . . . f℥xij.—M.

S.—Use several times daily as a gargle together with mustard foot baths. The use of tobacco is to be interdicted.—*L'Union Médicale*, June 23, 1885.

A CASE OF CHLOROMA.—DR. F. G. GADE, of Christiana, has had a case of the rare disease called chloroma, chlorosarcoma, green cancer, and periosteal and metastatic sarcoma, which was first described by Balfour, in 1834, and of which ten cases have already been recorded. Gade's case was in a little girl aged 5, who first suffered from anæmic symptoms, and then from a tumor of the left cheek, with toothache, tinnitus aurium, otorrhœa, deafness, and continually increasing exophthalmos. Nine weeks after these symptoms appeared, she died with pyrexia and great prostration, without having exhibited any phenomena of cerebral mischief. At the post-mortem examination, an immense number of greenish-yellow and greenish-gray fibrous tumors of sarcomatous structure were found in various situations, but more especially connected with the periosteum. They were found on the dura mater, in the internal ear, in the orbit, in the periosteum of the skull and facial bones, in large numbers on the sternum, on the ribs and vertebral column, also in the liver, kidneys, colon, lateral ligaments, and the medulla of the bones; also on the lower extremities there were a number of livid spots, the largest of which contained a butter-like substance. The case is very similar to those previously recorded, which were all in children. The green coloring matter, which can be dissolved out by maceration in chloroform as a dark-green oily liquid, is not related, according to Gade, agreeing with Otto, either to the blood or to the biliary coloring matter, but is formed from fat-granules, great numbers of which are found in the cells of the neoplasm.—*British Medical Journal*, July 11, 1885.

POWDER FOR PHAGEDENIC CHANCRE.—M. TERRILLON recommends the following powder as useful in phagedenic chancre:

℞.—Acid. pyrogallici . . . ℥v.
Pulv. amyli . . . . ℥iss.—M.

S.—Mix carefully.

In phagedenic anfractuous chancres, insufflate the powder into the depths of the sore. The dressing should be applied twice daily. The preparation employed should be fresh, and preserved from moisture in a well-corked bottle.—*L'Union Médicale*, July 4, 1885.

A CASE OF LACTOSURIA.—DR. GAUBE reports a case of lactosuria in a child aged fourteen days. The first five days after birth the child was fed on milk and water, owing to the slow establishment of the lacteal secretion in the mother. From the fifth day, the child fed regularly. The day succeeding birth it was seized with diarrhœa, accompanied at first with infrequent vomiting. Examination showed the milk of the mother to be excellent. The fecal discharges were acid, and composed of milk unchanged by intestinal digestion. The child, in the meantime, wasted. The urine on examination was found to have little color, no odor, and to be acid. Boiling produced no reaction. When added to boiling Fehling's solution, no precipitate appeared, but when boiled and added to the solution the characteristic precipitate occurred on cooling. Treated with the subnitrate of bismuth and caustic soda, and heated, it at first turned green, then yellow, and reduced the subnitrate of bismuth. Heating and testing with hydrochloric acid produced no change of color. Sufficient urine could not be obtained at one time to note the specific gravity. An average of two analyses gave about twenty-three grains of urea to the litre of urine, and the amount of urine passed in twenty-four hours was about four ounces. The urine contained no albumen, indican, nor oxalic acid.

As it is difficult to explain the formation of grape sugar in an infant entirely nourished with milk of a good quality, the conclusion was reached that lactosuria, not glycosuria, was the affection to which the symptoms were due.

The child, at the date of the report, when twenty-four days old, had improved in digestion, its weight increased; and the urine, which contained the same proportion of urea per litre, was neutral and reduced neither Fehling's solution nor bismuth.—*Gaz. Méd. de Paris*, June 6, 1885.

UNGUENT FOR THE TREATMENT OF METRITIS.—MARTINEAU recommends the following ointment in the treatment of metritis:

℞.—Potassii iodidi . . . . gr. lxxv.
Ext. belladonnæ,
Tr. benzoini . . . āā ℥ss.
Sodæ hyposulphit. . . . gr. viij.
Ol. amygdalæ dulc. . . . ℥ij.
Adepis benzoinat. . . . ℥vss.—M.

S.—Ft. unguent. Apply on wadding within the cervix.—*Revue de Thérapeutique*, July 1, 1885.

COCAINE BY INSUFFLATION AND INHALATION.—DR. SCHNITZER, recommends the following formula of cocaine for

A. Inhalation:

℞.—Cocaine hydroclor. . . xvj 16 to ℥ss.
Potassii chlorat. . . . . ℥ij.
Aquæ laurocerasi . . . . . f℥ss.
Aquæ dest. . . . . f℥xij.

B. Insufflation:

℞.—Cocaine hydrochlorat. . . gr. xij to xvj.
Morphiæ hydrochlorat. . . . gr. vj.
Bismuthi subnitrat.
Sacch. alb. . . . . āā ℥j.

—*Gazzetta degli Ospitali*, June 28, 1885.

REGENERATION OF THE SPLEEN IN THE FOX AFTER TOTAL EXTIRPATION.—PROFESSOR ETERNOD, of Geneva, publishes (*Rev. Med. de la Suisse Romande*, January 15, 1885) an interesting account of his researches on this point. His results are confirmatory of Tizzoni's The chief point of interest was that, four months after the spleen had been entirely removed, a nodule of newly formed splenic tissue was found, enclosing in its substance foreign bodies that could only have been introduced through the wound at the time of operation. The nodule was 13 millimetres long and 8 broad; and apart from some embryonic tissue, in microscopic character it was almost identical with the normal spleen. Amongst the other conditions found, the most noteworthy were the new formation of adenoid tissue, especially in the lymphatic glands and Peyer's patches, and the transformation of the parenchyma of lymphatic glands into splenic tissue. This last circumstance supports the view held for some time by Professor Eternod, that the spleen is only a vast elaborated lymphatic gland.—*British Medical Journal*, July 4, 1885.

A CASE OF SUBACUTE OSTEOMYELITIS OF THE INFERIOR END OF THE FIBULA: OPERATION AND RECOVERY.—DR. GÉRARD MARCHANT reports a case of subacute osteomyelitis of the lower end of the fibula in which operation was successfully performed by PROFESSOR TRÉLAT.

After chloroformization and the application of Esmarch's bandage, an incision was made along the external face of the diseased bone. An interesting condition observed was the enlargement of the musculocutaneous nerve. The periosteum was not increased in thickness, but adhesion to the bone was slight. After removal of the periosteum the bone was found to be increased in all its diameters, thus filling up the interosseous space. Along with the increased size, general change in the characteristics of the bone existed. The canaliculi had disappeared, as also the details of configuration. In the region of the anterior four or five aperitres could be seen and felt. Examination further showed that from its condition the bone could be divided into two zones, an upper and a lower, corresponding respectively to the middle and its malleolar portions. The inferior zone was slightly united and violaceous, its Haversian canals enlarged and exhibiting at several points drops of dark blood. The superior zone was white, and duller, denser, and more compact, though possessing neither the brightness nor regularity of sound structure.

The boundary between the two portions was marked by an irregularly traced line, resembling a boundary line in a geographical map. These macroscopic lesions confirmed M. Trélat in the opinion that an osteitis existed, and he proceeded to remove the diseased tissue in the upper zone with the chisel and trephine. The lower zone next received attention, and the unhealthy bone removed. The marrow of this portion was found to be diseased, exhibiting in the midst of osseous trabeculæ, which were infiltrated with dark blood, small islands of a yellowish dark substance, about the size of an almond, irregularly outlined, with a *curette a lunette*. M. Trélat removed the diseased marrow for a distance of about two inches, until the diseased foci no longer were evident. The bone was also scraped until all the necrosed tissue was removed. In two months the wound was healed and the patient cured, the only complication ensuing being a suppurating lymphangitis. In slightly more than three months the patient was able to walk, and was radically cured.—*Le Progrès Medicale*, May 30, 1885.

A CASE OF MILKY HYDROCELE.—MR. SIDNEY DAVIES, in the *British Medical Journal* for June 20, 1885, reports the following case of milky hydrocele, obviously caused by the *filaria hominis*. He says:

A Greek, aged 23, consulted me in November last for a swelling of the left testicle. The swelling had the appearance of hydrocele, which disease is common in this country. Accordingly I tapped it, and drew off two ounces of milky fluid. This fluid coagulated on boiling, and, after standing a day, separated into a thick and thin portion; in fact, it had the ordinary properties of chyle. Under the microscope it was found to contain fat granules and granular leucocytes. Among the latter were seen moving three or four embryonic filariæ, of the same appearance and proportions as those I have frequently seen before in the blood of patients with chyluria.

The patient was born in Alexandria, and had lived there until four months previously to my seeing him, when he entered the Cairo police force. He noticed the swelling of the testicle nine months before consulting me. He had twice suffered from gonorrhœa, and had had a "soft sore," but no other disease. He had never had chyluria nor hæmaturia.

In three weeks after tapping the fluid returned, having the same appearance as before. After consulting with Dr. Grant Bey, I determined, by his advice, to open up the tunica vaginalis, and allow the sac to granulate from the bottom. I accordingly cut down into the chylocele, and exposed the testicle. The sac was washed with a 1 in 20 solution of carbolic acid, and a large drainage-tube inserted. The patient had an attack of hæmaturia, presumably from absorption of carbolic acid, which lasted two or three days. There was free suppuration, with rather severe inflammation of the coverings of the testicle round the wound; but the wound healed completely in three weeks after the operation. Up to this date there has been no return of the disease.

THE PATHOLOGICAL PHYSIOLOGY OF THE TESTICLE.—PROF. ANGELO MAFFUCCI has recently performed numerous experiments upon the results of wounds of the testicle, to determine the following questions:

1. How wounds of the testicle result under different methods of treatment.
2. Whether the parenchyma of the testicle is reproduced after in any way it is destroyed.
3. Whether the portion of parenchyma regenerated possesses functional power.
4. From what histological elements of the testicular parenchyma the regenerated tissue takes its origin.

After a thorough investigation of the questions above proposed, as made by careful experiments on dogs, Prof. Maffucci reaches the following conclusions:

1. Under antiseptic treatment the parenchyma of the testicle is regenerated.

Digitized by Google

2. The regenerated epithelial tubules present phenomena of functional power.

3. The neoplastic parenchymatous tissue does not have its origin from old but from special cells of the stroma—with reservation for more exact observation.

4. The last proposition is a direct consequence of the preceding—*e. g.*, that there are special elements in the parenchyma of the testicle which have the power to renew it.—*Rivista Internazionale di Medicina e Chirurgia*, April, 1885.

GASTROTOMY.—The following case of removal of a foreign body from the stomach was reported in a recent sitting of the Dresden District Medical Society by Dr. Credé. A man aged 25, of delicate frame, came into his clinic after having swallowed, a fortnight previously, the whole set of teeth of his upper jaw. He had pushed the teeth down his throat because they were choking him, as he could not bring them up again. As they did not pass naturally, and signs of inflammation of the stomach became visible, Dr. Credé performed the operation. A diagonal cut 15 centimetres long was made below the ribs, the stomach was taken out, and opened by a cut seven centimetres long in the centre of its anterior aspect; the set of teeth was removed, and the rent in the stomach sewn up by three sutures, one above the other. The stomach was then replaced in its proper position. There was no inflammation, discharge, or pain of any kind. The second day after the operation, the patient received liquid nourishment, and after a fortnight solid food. In three weeks he was dismissed, and was able to resume his work. This is the second case in which a set of teeth that had been swallowed was removed by an operation, and the seventh in which gastrotomy was resorted to. The greater number of cases were successful. The first three cases were those in which a knife, a spoon, and a fork, respectively, had been swallowed.—*British Medical Journal*, July 4, 1885.

RARE FORM OF DISLOCATION OF THE SHOULDER.—A case of unusual dislocation of the humerus is described by Dr. K. E. Lindén, under the name of "luxatio humeri erecta," in the *Transactions of the Finland Medical Society*. The patient, a laboring man, aged 35, had been thrown down in a quarrel; and, while he lay on the ground, his opponent pulled his arm upwards, at the same time kicking him violently in the upper third of the left humerus. When Dr. Lindén saw the man, three days later, the humerus formed an angle of about 130 degrees with the acromion and clavicle; the forearm, which was pronated, lay horizontally over the head; the arm was much contused, and the seat of severe pain; while the hand which was supported by the right hand, was numb. All attempts at reduction caused much pain. The head of the humerus could be felt with unusual distinctness in the axilla, where it lay below and somewhat to the inner side of the glenoid cavity, resting against the lower border of the pectoralis major muscle. Reduction was effected, under chloroform, by making extension upwards and outwards. The arm was useless for six weeks; two and a half months after the injury, the man was able to walk, though his arm was still weak. Dr. Lindén has been able to find only five cases of this form of dislocation recorded in medical literature: two by Middledorpf, who first described it in 1858, and gave it the name of "luxatio humeri erecta;" one by Busch (1863); one by Nikolaysen (1873); and one by Alberti (1884). In all the cases, the arm was forcibly extended upwards when the displacement occurred. The symptoms in all resembled those described by Dr. Lindén as met with in his case: the head of the bone lay below the glenoid cavity, at the inner border of the scapula; the deltoid muscle was enlarged; the humerus was raised above the horizontal plane; and the forearm rested on the head, the hand being supported by that of the other arm. With regard to the difficulty of reduction, Dr. Lindén attributes it to the catching of the greater tuberosity of the humerus against the edge of the cavity of the joint.—*British Medical Journal*, July 4, 1885.

RETENTION OF URINE IN A CHILD OF SIX MONTHS.—M. ARNOZAN, in the *Journal de Médecine de Bordeaux*, reports the case of a child, six months of age, who suffered from retention of urine, The child had previously been healthy, and had had no difficulty in urinating, but when seen by M. Arnozan had not urinated for thirty-six hours. It cried and vomited. The bladder was found firm and full in the hypogastrium. The testicles were retracted. The penis and perineum presented no abnormal condition. Catheterization was performed without difficulty with a small elastic Charrière catheter, and urine, very dark but clear, to the amount of nearly four and a half fluidounces was drawn from the bladder. The child at once was relieved and went to sleep. Two or three days subsequently the urine became slightly purulent, and catheterization was continued for ten days, at the end of which time urination occurred spontaneously. Catheterization was required subsequently but once. The child since the attack has been in good health, but when suffering even from slight indisposition slight transient difficulty in micturition is manifested.—*L'Abeille Médicale*, June 29, 1885.

SCROTAL CALCULI.—DR. SCHKOTT has recently described, in a Russian medical periodical, the case of a patient, aged 27, who, when a child, was subject to some obscure disease of the scrotum, and noticed, later on, that he apparently had developed a third testicle, much harder than the two normal glands. For seven years before he came under Dr. Schkott's care in hospital, he frequently passed blood in his urine, and for two years micturition and coitus had been attended with pain. The third testicle reached the size of a goose's egg. Three months before admission he struck the scrotum, which inflamed and suppurated. The abscess burst, and left a fistulous track. On passing a probe into the track, three hard substances, which could be moved separately, were distinctly felt. On passing a catheter, a fistula was detected in the membranous part of the urethra. The scrotum was incised, and seven uric acid calculi were found in a capsule of connective tissue, fitting closely against each other. Dr. Schkott excised the sac after extracting the calculi, and closed the urethral fistula first with catgut, and then sutured the scrotal wound with the same material. The fistula opened up again, but was successfully closed by a second operation.—*British Medical Journal*, July 11, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, AUGUST 1, 1885.

THE SCORBUTIC TAINT.

AMONG the improvements in health and comfort which are due to preventive medicine, none are better marked or more susceptible of demonstration than those resulting from the prevention of scurvy. It is true that it is somewhat difficult to realize the extent to which a century or more ago, this disease or dyscrasia affected the people, in a mild form complicating all other diseases, and in its graver aspects producing epidemics, and destroying the efficiency of navies and armies.

Some idea of the prevalence of the scorbutic taint in those days may be gained from the records of medical practice in the seventeenth, and first half of the eighteenth centuries, in which the occurrence of symptoms referable to this complication is frequently noted.

It is true that in those times the terms scurvy and scorbutic symptoms were often used vaguely and as a cover for ignorance, very much as the term malaria is sometimes employed at present, but it is evident that the physician of 1600 saw so much of this disease, that he suspected its presence as a complication in a large proportion of the cases which he was called upon to treat. As an example of this, take the little book entitled "Select Observations on English bodies; or cures both empericall and historicall performed on very eminent persons in desperate diseases." Written by John Hall in the beginning of the seventeenth century.

John Hall was the son-in-law of Shakespeare, and lived at Stratford-on-Avon, where, in the words of his translator "he was very famous, as also in the counties adjacent." His little book, containing the record of nearly two hundred cases, was first published in 1657 by Dr. James Cooke, and is somewhat rare, being sought for by collectors of Shakespeariana. In the preface the editor says, "It seems the author had the happinesse (if I may so stile it) to lead the way to that practice almost generally used by the most knowing, of mixing scorbutics in most remedies," and scurvy grass figures in many of his prescriptions.

At the present time and in this country fully developed scurvy is so rare that many physicians have never seen a case which they have recognized as such, and do not suspect its presence even when it would be well that they should do so. It must be remembered that the causes which produced scurvy two hundred years ago are still efficient, and that those who, either from choice or from necessity, use salted meats too exclusively and do not use sufficient vegetables, are liable to suffer from these causes.

Fortunately, in such cases there soon arises a special craving for fresh vegetables and vegetable acids, but this is not always the case, and within the last three years we have seen several cases in people in comfortable circumstances in which the scorbutic taint was apparent when attention was directed to it, although it was not at first recognized, and the cases were considered to be rheumatic, malarial, dyspeptic, etc. In two of these cases the gums were decidedly spongy, and there were well-marked vibices on the front of the tibia, and in all of them attention to diet and the free use of lemons produced rapid improvement. It may be well, therefore, to bear in mind the possibilities of this complication, especially when prescribing a course of diet and regimen which is to be followed for a considerable period.

PNEUMONIA COCCUS IN THE AIR.

IN the course of some experiments on microörganisms in the air, PAWLOWSKY, of the St. Petersburg Pathological Laboratory, found on the exposed gelatine plates a culture which, in macroscopic characters, resembled closely those of Friedländer's micrococcus of pneumonia, and, on microscopical examination, proved to be composed of diplococci, some of which presented capsules. There had been cases of pneumonia among the laboratory servants, and this strengthened the supposition that these were pathological organisms. Two white rats were injected with these cultures, and death followed in twenty-four hours. There were pleurisy and hyperæmia of the right lung, and the organ sank in water. The diplococci were found in the exudate and in the lung. Cultures made from them seemed characteristic in the nail-form of the growth; but there were, in addition to Friedländer's large micrococci, smaller ones which it was found impossible to isolate. Further inoculations were made in two rabbits, one guinea-pig, and three dogs. In the rabbits there were fibrinous pleu-

Digitized by Google

risy and croupous pneumonia of the entire lobe of the right lung. In the guinea-pig there was a hemorrhage in the lung surrounded by a zone of grayish tissue, while in the dogs there were fibrinous pleurisy and many foci of gray, solid, airless tissue, in which the alveoli were filled with fibrin and colorless blood-corpuscles. The diplococci were most numerous in the rats.

It is not a little peculiar that servants with croupous pneumonia should contaminate the exposed gelatine plate; we can scarcely suppose they were in the laboratory during the existence of the disease, but the details on this point are rather meagre. The author refers to several features of interest in connection with the organism which has been found associated with pneumonia. Morphologically and physiologically great differences exist in the diplococcus described by different writers. The capsule which Friedländer believed to be specific, has not been found by many other observers. Salvioli describes the coccus as motile. Some have described a large diplococcus, others a small; and again, the results are different. Talamon and others have not been able to cause the pneumonia in dogs, which the author and Lebedinsky have successfully induced. In rabbits negative results followed the experiments of Friedländer; positive, those of Talamon and others. The author concludes that the organism with which he was dealing corresponded in form, mode of growth, and in the effects produced, with Friedländer's coccus of pneumonia. The smaller diplococcus which existed in the cultures was not thought to vitiate the results—indeed, Afanassiew has found both forms in pneumonic sputum.

THE SURGERY OF CYSTS OF THE PANCREAS.

THE *American Journal of the Medical Sciences* for April contains an exhaustive paper, by DR. SENN, of Milwaukee, on the "Surgical Treatment of Cysts of the Pancreas," an affection which, for obvious reasons, is not only extremely difficult of diagnosis, but rarely comes under the domain of the surgeon.

In his own case, that of a young man nineteen years of age, a cyst, containing three quarts of fluid, had developed in five weeks, as the result of a severe fall and blow, through which it was assumed that the pancreatic duct had been lacerated, that the pancreatic fluid infiltrated the gland, and that the cyst formed at the expense of its parenchyma and by distention of its capsule. For the first two weeks after the injury, diarrhœa and vomiting were prominent symptoms, and were followed by the appearance of a round, smooth, fluctuating, and painless tumor, which, on admission to the hospital, was found to occupy nearly the whole epigastric and the entire left hypochondriac region. The cyst was exposed by an oblique incision, five inches in length, made through the abdominal wall over its most prominent portion; the omentum, covering and slightly adherent to the cyst, was opened by an incision three inches long; the fluid was evacuated by cutting into the sac, and the edges of the incision were united to the parietal peritoneum, which had previously been stitched to the skin. Two large drainage-tubes were inserted, antiseptic dressings were applied, and the cure was complete in eight weeks.

The case of Dr. Senn is the sixth on record in which cysts of the pancreas have been subjected to operative interference. In 1881, Rokitansky attempted extirpation of the sac, but this was rendered impossible by the firm and numerous adhesions, and death ensued from purulent peritonitis. Nine months subsequently, Bozeman successfully removed a cyst, which, with its contents, weighed twenty-one pounds and a half. In the remaining four cases, in the hands, respectively, of Kulenkampff, Gussenbauer, Thiersch, and Senn, pancreatotomy was performed, and all of the patients recovered, one having a permanent fistula. From the deep situation of the pancreas, the shortness or absence of a pedicle, and the anatomical relations of the organ, extirpation is of doubtful propriety, while antiseptic incision appears to be a safe and efficient procedure, although it may subject the patient to the annoyance of a persistent fistula.

THE TITLE OF DOCTOR.

IN the *Medical Times and Gazette* for July 4 will be found described a scene at a medical book-club dinner in England, wherein the *dramatis personæ* are Stavesacre, a brand-new Brussels M. D., Cowhage, a M. R. C. S., L. S. A., and Broom, an M. D., Cantab. Stavesacre, who had previously been a licensed practitioner, but not an M.D., had yielded to the pressure of various kinds which has resulted of late years in a passion on the part of certain English practitioners for a right to use the doctor's title rather than that of Mr., had "run over" to Brussels and secured the M.D.,—after how long residence is not stated. The conversation is upon this event in the life of Stavesacre, who admits that his old diplomas were as good as half the M.D.'s about, but "the public somehow thinks otherwise." Further, according to Stavesacre, it is less "shoppy;" "a plain Mr. on a doorplate may be a piano-tuner for all the world knows," and "besides it is very convenient to be called doctor."

Broom, the Cambridge doctor, who has won his title by hard work, thinks on the other hand that the "Dr." is the more shoppy title; and that you can never shake it off. He detests advertising his business, and having always the look of "touting" for patients. Besides, the more one respects the title

Digitized by Google

of "Dr." and what it ought to imply, the more one hesitates as to one's worthiness of it.

Cowhage complains of the M.D. as a "conventional and accidental standard of superiority." A young man, whose father happens to have more money than another's, is sent to a school where he can get a title, and may not be a whit more worthy to be called Dr. than half a dozen others. "It is monstrously unfair," says Cowhage.

But Broom again charges his friends with wrangling about the shells and letting the oysters drop. Those patients that choose the doctor by his doorplate are infinitesimally few, and little worth having. The best patients are those who judge the pudding by the taste, and not by the elegance of its recipe, who come to you because of the good report their friends give of you, and not because of any university *imprimatur*. "No," he says, "let us stand on our own bottom, and despise such fortuitous and rickety elevations as diplomas and degrees. If we work so as to win confidence in our own efficiency, throwing off all pretence to be what we are not, why then we shall earn, not perhaps fame and fortune, but our own and others respect, which, considering all things, is the best reward that a poor practitioner can look for."

To any one who, without prejudice, examines all sides of this question, it is evident there is some truth in what each one of these medical men says. But it seems to us plain, also, that the Cambridge doctor has the best of the argument, and that he who follows the line of motive laid down by him will not only be the happier man, but ultimately the more successful physician in every sense of the word.

We desire, particularly at this time, to call the attention of our British cousins to this matter and these facts, because our own country is again becoming the focus towards which foreigners are turning their attention with a view to obtaining the title of doctor. Few as yet have forgotten the smirching which the American degree received some years ago by the wholesale issue of bogus diplomas on this side of the Atlantic, diplomas which were boldly sold in England and Scotland, in France, Germany, and Italy. We are in a position to know that many of these diplomas were bought by foreigners in good faith—that is, they thought they were obtaining them from respectable institutions.

Recently, we say, there is again a disposition to look to America for easily obtained doctors' titles. Many of these applications come from honest intentioned men, some of whom are willing to pass an examination, but few are willing to attend the single course of instruction which is alone required by the colleges of this country to make the regularly licensed practitioner of Great Britain eligible to examination for the degree. Unfortunately, too, we note that two or three American colleges which lay claim to respectability, are bidding, as it were, for candidates of this kind by advertising their short courses in the English journals, and we are aware of at least one instance in which a degree was conferred by one of our western colleges upon an English licentiate without attendance, but on examination only. Let them beware. They are treading upon dangerous ground.

INCEST AND IDIOCY.

THE results of recent investigation only go to confirm those of a less modern date in showing that the history of Œdipus Coloneus does not represent the type of the offspring of incestuous marriages. Œdipus, one of the most unfortunate of mortals, who unwittingly slew his father, and became partner of his own mother's bed, had sons and daughters who were perfect in intellect and in body. One of the daughters, indeed, must be regarded as showing a nobleness of character and life, and a loftiness and heroic resoluteness of purpose almost unequalled by any woman of ancient or modern times. As Penelope stands forth the Greek type of wifely love and fidelity, so does Antigone represent a daughter's fearless devotion to her unhappy father, and a sister's to a brother.

But according to Legrand du Saulle's recent investigations, as published in the *Journal D'Accouchements* of June 30th, the children of incest are peculiarly liable to mental or physical defect, or to disease. He gives seven illustrations, five of which we will briefly state.

A girl nineteen years of age had been the mistress of her father for three years, and by him she had three children, two of whom died early from convulsions, while the third had clubfoot.

A girl sixteen years of age, was deflowered at thirteen by a brother; this brother left to become a soldier, and she then had sexual intercourse with a younger brother, seventeen years old, and from this relation she gave birth to an idiot child.

A woman thirty-three years of age, insisted upon being the mistress of her son, who was nineteen years old; the offspring of this unnatural association was an idiot.

In another instance a woman thirty-nine years old, but still beautiful and of high social position, had a son nineteen years old, whom she regarded as an Apollo. She became his mistress, and gave birth to a child that died of convulsions in the third year.

A father debauched his daughter of fifteen years; he found her pregnant after a time, and hung himself; four months after his suicide, she gave birth to a child which lived and was an idiot.

These facts are of very great interest in mental pathology, and they likewise have their moral lesson. They tell us that there are laws which cannot be violated with impunity, and that the vengeance falls

Digitized by Google

upon the offspring of incestuous relations, the sins of the fathers and mothers visited upon the children. The Eumenides of Greek tragedy no longer walk the earth; they were the dark shadows of eternal, immutable, omnipotent law which is now recognized, but not yet fully comprehended.

HYDATID DISEASE AT THE PATHOLOGICAL SOCIETY.

IT is a rare event at any Society to have such an exhibit of cases of hydatid disease as that at the Pathological Society of Philadelphia at its last meeting, on June 25th. In the first place, Prof. Osler exhibited, under the microscope, hydatids found in the urine of a case of hydatid disease of the kidney, the cysts from which are passed periodically and coincidently with symptoms of nephritic colic and a sense of fulness in the region of the kidney. It is believed that this is the only case of hydatid disease of the kidney which has ever been reported as occurring in American practice.

Next, Dr. Longstreth exhibited six specimens of hydatid disease, all of unusual interest. The first was one of hydatid cyst of the liver, with resulting obstruction of the common bile-duct, associated, during life, with attacks of biliary colic of so peculiar a character that it was at least concluded that they were not due to gall stones. The second was a case of hydatid disease of the liver, with hydatid cyst of the pelvis, which during life pushed up the bladder in such a way that its cavity could not be reached by the longest catheter in use. The third and fourth were also cases of hydatids of the liver. The fifth and sixth were instances of hydatid disease of the brain, in one of which the cyst, probably half an inch in diameter, lay in the longitudinal fissure. The other was a brain in which were two hydatid cysts.

A very interesting fact in connection with these specimens, all of which belong to the Museum of the Pennsylvania Hospital, is that five out of the six were from foreigners, two being Frenchmen, two Italians, one a Portuguese, and one a colored woman. The question of the possible occurrence of this form of disease in native-born Americans was, however, settled by the fact that the patient from whom Dr. Osler's specimen came, although an Englishman, had lived thirty-five years in America; and one of Dr. Longstreth's was a colored woman, native to the country.

The undoubted rarity of the disease on this side of the Atlantic, well shown by Prof. Osler's statistics, published in the *American Journal of the Medical Sciences* for October, 1882, can only be ascribed to the less intimate relation of our people with dogs, which are the natural habitat of the tænia echinococcus, the parent of the echinococcus cyst. It is interesting, also, to note that two of the Frenchmen were dog fanciers, one having been in the habit of biting off the ears and tails of dogs he was raising.

THE NON-INJURIOUS EFFECT OF ANTIPYRINE IN PREGNANCY.

CHIARA, *Annali di Ostetricia*, gave to a woman in the ninth month of pregnancy, who was attacked with pneumonia, antipyrine. A remarkable reduction of temperature followed, but premature labor came on.

The question naturally arose as to whether the antipyrine brought on labor, and, to settle the matter as to whether this medicine has any oxytocic power, he gave sixty grains of it, in divided doses, to twelve pregnant women, seven of them not yet in the ninth month; the others near the period of labor. In none was any injurious result observed, the pregnancy being undisturbed. So far, therefore, from attributing any unfavorable influence to antipyrine given in pregnancy, Chiara regards it as having a favorable influence, for, by the reduction of temperature it effects, the occurrence of premature labor, of which pyrexia is so frequently the cause, is prevented.

REVIEWS.

A SYSTEM OF MEDICINE, BY AMERICAN AUTHORS. Edited by WILLIAM PEPPER, M.D., LL.D., Provost and Professor of Medicine and Clinical Medicine in the University of Pennsylvania; assisted by Louis Starr, M.D., Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania. Volume II. Pp. 1312. Philadelphia: Lea Brothers & Co., 1885.

THE second volume of this great work has been issued promptly and fully bears out the promise of the first. The general diseases are brought to a conclusion and the remainder of the volume is occupied with "Diseases of the Digestive System." Thirty-eight articles are contributed by twenty-two authors against thirty-two by twenty-one authors in volume one. It is to be hoped that the increase in bulk will not be progressive as the work goes on; the limit of convenience as regards size has been reached.

The volume opens with an able and carefully prepared consideration of rheumatism and rheumatoid affections, from the pen of Dr. R. Palmer Howard, of Montreal. Gout, by Dr. W. H. Draper, of New York, follows naturally. We should like to have had from the author a more positive expression of opinion as to the prevalence of the disease in this country. Rachitis, by Dr. Jacobi, of New York, and Scurvy, by Dr. Wales, are exhaustive articles by men of extensive experience and wide reading. Dr. Tyson, of Philadelphia, writes upon Diabetes, a disease with which his name has long been associated as a worker in its clinical and pathological aspects. Dr. Lynch, of Baltimore, writes the article on Scrofula. It is a pity that the numerous recent researches which go far to show the identity of tuberculosis and scrofulous affections, could not have been

Digitized by Google

incorporated. Hereditary Syphilis is considered by Dr. J. William White, in an elaborate and critical article of over sixty pages.

The Diseases of the Digestive System occupy the remainder of the volume. The editor might have cut down with advantage the articles on the orifices, so fully dealt with in the surgical systems; fifty-six pages on the Mouth and Tongue, by Dr. Cohen, of Philadelphia, and forty-three on Anus and Rectum, by Dr. T. G. Morton, and Dr. H. M. Wetherill, of Philadelphia. Dr. Cohen also writes the Sections on Diseases of the Pharynx and Œsophagus; and it is superfluous to say that they are well written. The articles on Functional and Inflammatory Affections of the Stomach are from the pen of Dr. Armor, of Brooklyn. The other diseases of the stomach—ulcer, cancer, etc., are considered by Professor W. H. Welch, of Johns Hopkins University, in a series of papers which exhaust the subjects and will be for many years to come the standard work of reference on these important topics. The articles on Diseases of the Intestines occupy over three hundred pages, and are contributed by W. W. Johnston, of Washington; J. T. Whittaker, of Cincinnati; J. Lewis Smith, of New York; Philip S. Wales, of Washington; Hunter McGuire, of Richmond; Joseph Leidy, and I. Edmondson Atkinson, of Baltimore. Dr. Bartholow takes the entire subject of Diseases of the Liver. The Assistant Editor, Dr. Starr, deals with the Diseases of the Pancreas. Dr. Alonzo Clark, of New York, contributes the article on Peritonitis; no one else in the country could have done it so well, or so appropriately, as the man to whom we owe the opium treatment of the disease. The volume concludes with an article on Tabes Mesenterica, by Dr. Busey, of Washington.

An extraordinary index accompanies the volume; one hundred and eighteen pages! bewildering in its fulness, and much of it superfluous.

The third volume, we understand, will be ready by the first of October, and the work will be completed early next year.

MATERIA MEDICA AND THERAPEUTICS; AN INTRODUCTION TO THE RATIONAL TREATMENT OF DISEASE. By J. MITCHELL BRUCE, M.A. Aberd., M.D. Lond.; Fellow of the Royal College of Physicians; Physician and Lecturer on Materia Medica and Therapeutics, Charing Cross Hospital; Assistant Physician to the Hospital for Consumption, Brompton. 16mo. pp. 547. Philadelphia: Henry C. Lea's Son & Co., 1884.

THIS volume is another of the excellent series of student's manuals, and is so full of information that the first year's student is charitably advised to confine his attention to the materia medica proper, and under the action and uses of the drugs, to read only those portions printed in thick type. As stated in the preface, it is therapeutical in its scope, and intended to be a rational guide to the student and practitioner of medicine in the treatment of disease. The antiquated method of classifying medicines in accordance with their effect upon the human system, is discarded in favor of a natural arrangement, in which articles of the inorganic materia medica are comprised in groups of metals, acids, alkalies, and so forth; whilst the two divisions of drugs from the vegetable and from the animal kingdoms, constitute the organic materia medica. The author attaches importance to his plan of systematically tracing the physiological action and uses of the different drugs in their passage through the body, from their first contact with it locally, until they are eliminated in the various secretions. He urges that his innovation of discussing the action and uses of remedies under the heads of the physiological systems of the body such as the digestive, the respiratory, etc., aids in conducting the pupil from facts with which he is familiar to the great principles of treatment. Whilst the value of this volume to American students will be somewhat diminished by the fact that it is intended chiefly as a commentary upon medicines officinal in the *British Pharmacopœia*, we can cordially recommend it to those of our readers who desire to be fully informed upon the opinions held abroad as well as at home, in regard to the many unsettled problems of therapeutics.

SOCIETY PROCEEDINGS.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated Meeting June 25, 1885.

THE PRESIDENT, E. O. SHAKESPEARE, M.D., IN THE CHAIR.

DR. WM. OSLER exhibited for DR. MCLAREN, of Paisley, Ontario, some specimens, which he had sent him, of

HYDATIDS PASSED WITH THE URINE,

with the following history, dated April 13, 1885. The patient, Geo. S., aged 58, an Englishman, resident of Ontario for thirty-five years, at present a farmer, but formerly a butcher for fifteen years. Always enjoyed good health until about four years ago, when he had a severe attack of nephritic colic on the right side, lasting only a short time and quickly relieved. Had no further trouble until two years afterwards, when a similar attack occurred, confining him to bed for several weeks; some days he was better, but always worse on exertion. After a period of improvement for several weeks, during which time he was able to attend to his farm duties, he felt pain and uneasiness over the right kidney followed in a day or two by pain at the point of the penis, which continued for several hours and was relieved by the passage of gelatinous-looking masses in the urine. These bodies—hydatid—he has continued to pass at intervals of from two to four weeks. The discharge is always preceded by an uncomfortable feeling of fulness in the region of the kidney and pain or uneasy sensations at the penis. No tumor has at any time been discovered in the neighborhood of the kidney. With the exception of these attacks of pain and distress in the urinary organs, prior to the discharge of the hydatids, he enjoys good health. He lost no weight; appetite good; bowels regular.

The specimens, which were given to me for examination by Dr. Palmer Howard, of Montreal, consisted of ten or a dozen hydatid cysts, ranging in size from a pea to a grape, and contained in a small quantity of urine. They were evidently the daughter-cysts of a larger one which was in communication with the urinary

Digitized by Google

passages. Several of the cysts contained smaller ones (granddaughter-cysts). On examination of a drop of the urine in which they were, numerous hydatids and the characteristic hooklets could be seen.

Echinococcus of the kidney or urinary passages is very uncommon. Statistics show that the left organ is more frequently affected than the right. The points of interest in this case are: the long duration, the absence of evident tumor, and the excellent condition of the patient. Here is evidently a cyst of considerable size, possibly in the right kidney, and which bursts at times into the pelvis with the discharge of the hydatids.

In 1882 Dr. Osler reviewed the literature of American cases of echinococcus disease, and made inquiries of the curators of the principal museums, the result of which was the collection of sixty-one instances of the disease (*American Journal of the Medical Sciences*, October, 1882, page 475). In not one of these was the cyst in the kidney. Since that date six other cases have been reported, viz.: by Carson (cyst of liver), *St. Louis Courier of Medicine*, 1884; Schæffer (liver), *Trans. Med. Soc. of State of Pennsylvania*, 1884; Wier (liver and mesentery), *New York Med. Journal*, 1885; Helm (cyst of liver, ruptured into intestine), *New England Med. Journal*, 1883-4; Welch (spleen), THE MEDICAL NEWS, Jan. 19, 1884, page 80.

DR. MORRIS LONGSTRETH then exhibited a series of six specimens of echinococci situated in various organs.

CORRESPONDENCE.

LANGEN-SCHWALBACH AS A HEALTH RESORT.

To the Editor of THE MEDICAL NEWS.

SIR: The name Schwalbach was formerly Schwalbenbach (Swallowbrook), and according to folks-lore is derived from the charming legend of a maiden whose life was saved by a young swallow, to which she had been kind, and which, with other swallows, brought her in nutshells water from a spring, the virtue of which the swallow had discovered when herself ill. The future husband of the young girl, in gratitude, built a house for the sick about the marvellous spring. The latter became famous. A town arose, and to this day its coat of arms is a swallow and a brook.

In order to reach Schwalbach (or Langen-Schwalbach) the visitor may go directly to Mayence from Paris, then to Wiesbaden, and thence drive in a carriage or go by an uncomfortable diligence. Or the route may be taken *via* Ostend, rail to Cologne (ten hours), and boat to Coblenz. Pass the night (a superb bit of Rhine scenery here) and go on next day by train to Eltville. The express boats do not stop at Eltville. The other boats are too slow. From this place take a carriage (ordered beforehand from Schwalbach by telegram). The way lies through Schlangenbad, another bathing resort to which many patients are sent for baths before taking the cure at Schwalbach. The waters at Schlangenbad are "*indifferent*," that is, they possess no especial chemical or mineral properties, but when warmed seem to exert a soothing influence and thus prepare "nervous" or hysterical patients for the powerful waters of Schwalbach, the effect of which is very decided. I do not deem it necessary to spend any time at Schlangenbad (forty-five minutes from Schwalbach by carriage), but if patients are directed to do so, and especially if sensitive, they should not remain long, nor go out of doors after 5 P. M., except on very warm days, for the place lies in a deep valley, entirely shut in by hills very thickly wooded. The consequence is an atmosphere of extreme dampness.

Schwalbach lies upon three gentle hills, deep in a valley, formed by mountains of a moderate height, whose summits are crowned by superb forests. The springs lie 900 feet above sea-level. The air is pure and refreshing, and the temperature rarely exceeds 15° R. (65¾° F.) during the summer. The climate is healthful. Epidemics are unknown here, and there has never been recorded a single case of cholera. The average duration of the cure is six weeks, and I would advise patients to reach Schwalbach, at the latest, by the middle of June or the first of July. After the middle of August rains are frequent, and in the valley the dampness naturally soon becomes disagreeable to the delicate. Hotels are numerous, the best one being the Alleé-Saal, kept by Mr. Ernst Grebert, who is also banker for American letters of credit. It would be well to write him in advance, in order to secure sunny rooms. As a dependance he has a beautiful villa, which is very convenient for families. He will send breakfast and supper to the villa, but expects his guests to come to the hotel for the one o'clock dinner. There are also many pensions and furnished apartments which afford a more economical manner of living. The walks and drives about the place and vicinity are very charming, as are also, especially, the grounds of the bathing establishment. There is an excellent orchestra which gives three concerts daily. The Casino, a fine building belonging to the establishment, is the rendezvous in the evening. Here, concerts, balls, and various entertainments are given, and it includes a spacious reading-room in which may be found daily papers from every country. Circulating libraries are plentiful. The shops are very good.

Schwalbach is a quaint old town, straggling down the valley from the bathing section, which is very pretty and well arranged. For the privileges of the place, visitors, who remain longer than one week, are obliged to pay ten marks or two and one-half dollars. There are several springs which are used medicinally; only two need be mentioned. If one of the others is indicated, the resident physicians, Grebert (brother of the proprietor of the hotel, and a very skilful and agreeable gentleman), Genth, and Frickhoeffer, will give the proper directions.

The two springs at Schwalbach which are in common use are the Weinbrunnen and the Stahlbrunnen. Of these the former probably is sufficient for the majority of patients. As will be seen by the following analysis.

	Free carbonic acid in one pound of water.	Bicarb. of protox. iron in one pound	Bicarb. salts.
	Cubic inches.	Grains.	Grains.
Stahlbrunnen .	50.27	0.643	4.660
Weinbrunnen .	45.6	0.443	11.967

Digitized by Google

In this analysis I give merely the active ingredients, the Stahlbrunnen is richer in free carbonic acid and iron salts and consequently too strong for many persons:

There are but three known springs which contain more iron than the Stahlbrunnen. As to the proportion of carbonic acid gas, the latter is the most powerful of all known iron springs. The effects of the iron and carbonic acid gas are too stimulating to be borne with impunity by very delicate patients until toleration has been established. And here it should be said, that American women cannot bear the strength of water which seems to agree perfectly with the Germans. Patients should, therefore, be advised not to begin with the degree of strength of drinking water, nor remain in the baths for the length of time, which will probably be recommended by the resident physician. Moreover, the temperature of the bath at first should be warmer than is the rule.

I had the fortune to be able to watch the effects of these waters upon twelve or fifteen patients, who were under my immediate supervision. Two of them were so powerfully affected, even by diluted drinking-water and weak baths, that it became necessary for them to abandon both. This, however, is exceptional.

The Schwalbach waters are extremely beneficial in the cases for which they are indicated. Notwithstanding the relatively small proportion of iron, anæmia is often very rapidly relieved by the drinking water, which is quickly digested and assimilated. The large proportion of carbonic acid gas renders the water very stimulating, whether used internally or externally. The appetite is rapidly restored, the color returns to the face, the general strength increases daily, morbidness vanishes, the mind becomes tranquillized, chill and tendency to "take cold" disappear. In many cases this improvement is surprisingly rapid and the cure becomes what the Germans are fond of terming "brilliant." The cure is carefully systemized, the water being drunk, and the baths taken, at certain fixed hours.

Patients begin with the Weinbrunnen and after a stated period of three to four weeks, some are ordered to change to the Stahlbrunnen, but, as already remarked, the Weinbrunnen is sufficiently strong for Americans. A patient brings her glass and drinking tube (I say her, for the patients are nearly all ladies), takes them to the Weinbrunnen which flows into stone tanks beneath a pretty, open building, or rather a roof supported by posts, and there the women who dispense the water attach to the glass a number which the patient must bear in mind. At first only one-half the glassful should be taken, the quantity being gradually increased as directed by the physician. Everybody walks while slowly drinking through the tube, and the sight of scores of persons imbibing the water during a promenade is very comical. The drinking is repeated once or twice during the day. Diet is carefully regulated, especially salad and fruit being strictly forbidden.

The baths are conveniently arranged in a long two-story building which contains ninety-three chambers. Bath tickets (none being required for drinking) are bought by the package, and the name and hour of each patient are carefully recorded so that at the hour the bath is always in readiness. A steam whistle upon the bath-house is blown every hour, thus giving notice to those who bathe at that hour. The water is heated by steam, which is turned on a few minutes before the bath is taken, the attendant regulating the temperature with care according to the directions of the physician, who will suggest 25° or 26° R., or 88° or 90° F. This, I believe, is not sufficiently warm for the first bath, 29½° R. being only blood-heat. The temperature may gradually be lowered in later baths. The patient sits upon a wooden stool weighted with lead. A cover is put upon the tub to preserve the carbonic acid gas, to protect the lungs of the patient, and to avoid loss of heat. The local physician will direct the patient to remain in the first bath ten minutes and gradually to increase the duration of subsequent baths to twenty minutes. None of my patients, all of whom were Americans, could endure this length of stay without distress and not one of them was allowed, even in the later baths, to exceed eight minutes.

German women seem to be made of different material. They can drink more water and remain in the bath far longer than our countrywomen. A heated linen sheet and towels are provided for drying purposes after the bath and if requested the attendant will dry the patient. Very delicate invalids should not at first use water of full strength either for bathing or drinking. In the bath-houses are special chambers for the diluted bath and near the spring is a jar filled with ordinary water for the purpose of weakening the iron water. The baths are now so arranged that the water will not stain the clothing, as it formerly did, with iron rust. After the bath the patient goes to her lodging and rests upon the bed for at least one hour,

At first the effect of the bath is enervating, notwithstanding that for two hours after leaving the bath the skin is in a condition of great stimulation. Perspiration is common but disappears within an hour. The carbonic acid gas bubbles constantly during the bath and acts as a rubefacient. In case of weak heart the gas is frequently oppressive and gives the patient a sensation of weight upon the chest. Such cases should begin gently with diluted water, remaining in the bath only four or five minutes.

In order to meet the probable objection of the physician that such care is unnecessary, the patient should be furnished with a written request to this effect from her personal physician. One of my patients was the victim of a serious mitral affection, but by gentle and careful use of the water at first, she slowly advanced to water of full strength and was greatly helped by her stay in Schwalbach. It is sometimes the case that the water causes headache, vertigo, flushing of the face, and these sensations are experienced especially after a full meal. If the patient lie down the distress increases, while a short walk in the shade generally overcomes it. This effect of the water is not common. If toward the end of the cure these symptoms appear for the first time, it is an indication that the baths should be less frequent or discontinued. Constipation is rather frequent, and is regulated by the use of Hunyadi Janos or Friederichshall water. Exercise is urged upon all patients, and the daily promenade or donkey ride is gradually lengthened. No patient should bathe before breakfast. Many foreigners do this, but for American women it is unwise.

The cases which are benefited by the Schwalbach

Digitized by Google

waters may be briefly enumerated as follows: Anæmia; loss of nerve power: general muscular debility, including muscular tissue of the intestinal canal; chronic uterine catarrh; abortion; chlorosis; menorrhagia; relaxation and imperfect development of the uterus; prolapsus; sterility; dysmenorrhæa; metritis and all kindred affections; hysteria; hysterical paralysis; hyperæsthesia, and other similar nervous ailments.

The Schwalbach waters are not sufficiently known, nor are they prescribed by American physicians as frequently as they deserve. Their great value in the treatment of the nervous disorders which are so common among American women needs no further suggestion. The details I have given will I trust render it easy to send patients to these springs and likewise enable physicians to supply them with all necessary information. Living costs from $1.75 to $3.00 per day, according to circumstances. The expense of the baths is about fifty cents each.

HAMILTON OSGOOD, M.D.

THE DISINFECTION OF RAGS.

THE issue of the *New York Times* of July 7th, contained an article headed "Disinfection Unnecessary—Conclusions of the International Sanitary Conference of Rome." The author of this article, taking a report in the *British Medical Journal* as his authority, ventures to assume that the correspondent of the Philadelphia MEDICAL NEWS has "interpolated" a paragraph in his report upon disinfection. He says: "This paragraph appears in another form in a letter to a Philadelphia paper, written from Rome under date of June 3. The portion in parentheses is supposed to have been interpolated by the writer of the letter on his personal responsibility. The language used is as follows: 'Disinfection of merchandise and of the mails is unnecessary. (Steam under pressure is the only reliable agent for disinfection of rags—*les chiffons en gros.*)'"

In a letter published in *The Times* of July 11th, the subscriber officially denied that the correspondent of THE MEDICAL NEWS had interpolated the paragraph in parentheses, in the following language:

"This inference as to an unjustifiable interpolation is entirely without foundation. The report of the Committee on Disinfectants is correctly given by the correspondent of the Philadelphia journal referred to. The writer was a member of the Committee on Disinfectants which was constituted as follows: Sternberg, United States; Koch, Germany; Proust, France; Eck, Russia; Thorne-Thorne, England; Hoffmann, Austria; Semmola, Italy. There was no opposition to the paragraph relating to the disinfection of rags, either in the committee or in the Conference."

In *The Times*, of July 22d, there is a second article, not signed, in which the assertion is made that a gentleman *interested in the importation of rags* has received a cablegram from Dr. Robert Koch to the effect that the paragraph referrring to the disinfection of rags does not appear in the report of the Committee. This has been copied in the *New York Medical Journal*, and it becomes necessary for the delegate from the United States to defend himself from the charge of having added to the official record of the Committee on Disinfectants, of which he was a member.

Either Dr. Koch is mistaken, or he has been misrepresented by the gentleman *interested in the importation of rags*, for the official record of the proceedings of the Conference contains the paragraph in parentheses which, it is alleged, has been "interpolated" by the correspondent of THE MEDICAL NEWS, upon his "personal responsibility."

Attached to this note is a copy of the report of the Committee on Disinfectants of the International Sanitary Conference of Rome; also a copy of the translation given by the correspondent of THE MEDICAL NEWS.[1] The writer submits that Article V., which contains the paragraph alleged to have been "interpolated," has been correctly translated by the correspondent of THE MEDICAL NEWS, and correctly quoted by the writer in his letter to *The Times* (July 11th.)

The printed copy of the report accompanying this circular was distributed to the members of the International Sanitary Conference at the Session of June 2d. It corresponds with the *official record* as given in *Procès Verbal*, No. 10, page 3; and in the *Relevé des Conclusions Adoptées*, page 16.

The truth of this statement may be verified by referring to the printed copies of the proceedings brought by the subscriber from Rome, and now on file in the office of the Hon. Secretary of State, and of the Surgeon-General U. S. Army.

GEO. W. STERNBERG,
Major and Surgeon, U.S.A.,
Delegate to the International Sanitary Conference at Rome.

NEW INVENTIONS.

IMPROVED SPECTACLES FOR "FAR" AND "NEAR" MONOCULAR VISION.

BY R. R. GURLEY, M.D.,
OF BARNES'S HOSPITAL, WASHINGTON, D. C.

THE sides (with or without ear-hooks) rotate through three-quarters (instead of one-quarter) of a circle. The nose-piece is in the plane of the rims, not, as at present, at an angle to that plane. One side of the frame contains the "near," the other the "far" lens.

This saves the annoyance of two pairs of glasses, reversing being sufficient to change from "far" to "near" and *vice versâ*. A little thought shows that if two cylinders are required, the angle of *one* must be the *supplement* of the usual angle, as the direction of vision is reversed. Practically, this frame is very convenient.

A NEW PHIMOSIS INSTRUMENT.

BY R. W. KNOX, M.D.,
OF HOUSTON, TEXAS.

THE attention of the profession is called to a new forceps that will be found of service in excision of the prepuce, and in some other operations where a tissue- or suture-forceps is needed. The cut represents the instrument so accurately that a description is hardly neces-

[1] It is unnecessary to reprint here these somewhat lengthy documents, which fully justify the statements made by Dr. Sternberg.—EDITOR.

Digitized by Google

sary. Each blade resembles a tuning-fork, having an open slit running through its middle for the last two

inches of its length, and when brought into contact with its fellow is fastened to any degree of tightness by a slide-catch in the handle. The advantage over the ordinary clamp is readily noticed, in that it is more easily fastened upon the part, and when fastened no tension upon the prepuce is necessary for its excision, the cut being made through the slits with a sharp-pointed bistoury. The mouse-toothed extremity makes it a tissue-forceps, and its advantage in steadying flaps for the introduction of sutures will be readily seen.

NEWS ITEMS.

PROVIDENCE.

(From our Special Correspondent.)

THE FISKE FUND PRIZES.—At the annual meeting of the Rhode Island Medical Society, held in Providence, June 11, 1885, the Committee on the Fiske Prize Fund, through Dr. Charles L. Parsons, Charman, reported as follows:

(1) For an essay bearing the motto, "Behold How Great a Matter a Little Fire Kindleth," and upon the subject, "The Present State of the Germ Theory," the sum of $200 was awarded the writer, Dr. Charles V. Chapin, of Providence.

(2) For an essay bearing the motto, "*Quid nimium probat, nihil probat*," and upon the subject, "The Physiological and Pathological Effects of the Use of Tobacco," the sum of $200 was awarded to the writer, Dr. Hobart Amory Hare, of Philadelphia, Pa.

The following subjects were then announced for the current year:

(1) "The Methods and Practical Results of Treatment of the Malarial Diseases now Prevalent in New England."

(2) "New and Altered Forms of Disease Due to the Advance of Civilization the Past Half Century."

For the best essay on either subject, worthy of a premium, the writer will receive the sum of $200.

MORE RESIGNATIONS FROM THE NEW ORGANIZATION OF THE CONGRESS.—We are requested to state that Dr. H. N. Spencer, of St. Louis, declines to accept the Vice-Presidency of the Section of Otology, and that Drs. C. H. Mastin, of Mobile, and Harrison Allen and Morris Longstreth, of Philadelphia, also decline to accept the offices to which they have been appointed by the New Committee.

PROPOSED CHANGE IN THE MEMBERSHIP OF THE CONGRESS.—The following suggestion, we understand, has been forwarded to the New Committee on the Organization of the Congress:

Resolved, That the Council of the New York State Medical Association respectfully recommend to the Committee of Arrangements for the International Medical Congress the following modification of the rule by which the American membership of the Congress is to be constituted, to wit: That the American membership of the Congress be constituted of delegates who shall be entitled to participate in the business and scientific proceedings, and of members who shall be entitled to participate only in the scientific proceedings of the Congress; that the delegates may be appointed by the American Medical Association and by State and local organizations in affiliation therewith in the proportion of one delegate for every ten or fraction of ten members of the organizations thus represented; that members of the regular medical profession of the United States may become members of the Congress by registering their names as such and by taking out tickets of admission.—*New York Medical Journal*, July 18th.

In commenting on this proposed change in the rule of membership, *The Medical Record* says: "This is virtually no compromise, since no self-respecting physician would accept membership or do work under such conditions."

THE ALLEGHENY COUNTY MEDICAL SOCIETY AND THE INTERNATIONAL MEDICAL CONGRESS.—The Allegheny County Medical Society, at a meeting held in Pittsburg July 21, 1885, adopted the following resolutions, which were offered by J. B. Murdoch, M.D.

Whereas, The American Medical Association, at its recent meeting in New Orleans, saw fit to revise the action and annul the appointments of the original Committee appointed at Washington, to make arrangements for the Ninth International Congress; and

Whereas, The new Committee, at its recent meeting in Chicago, has made such changes in the arrangements for the Congress as in our opinion will mar its success and prove injurious to the interests of the medical profession as well as to the interests of the American Medical Association; therefore be it

Digitized by Google

Resolved, That the Allegheny County Medical Society disapprove of the recent action of the American Medical Association and its new Committee and respectfully recommends that the American Medical Association shall, at its next meeting in St. Louis, rescind its recent action and restore to the original Committee full power to make all the arrangements for the Ninth International Medical Congress.

Resolved, That the Secretary furnish a copy of the foregoing resolutions to the Secretary of the American Medical Association, and that he shall also furnish copies of the same to the *Journal of the American Medical Association* and to THE MEDICAL NEWS for publication.

PUBLIC OPINON ON THE CONGRESS ORGANIZATION.—The action of this Committee confirmed the gloomiest forebodings. The Committee chose as its officers men who, whatever may be their talents, had led the movement at New Orleans, and secured themselves in office. Many physicians who had accepted position in the Congress from the original Committee, despairing of the success of the undertaking in its new hands, determined to withdraw from the organization. Others, openly declaring they would not serve under such officers, also withdrew.

The meetings of the profession in Philadelphia, Boston, Baltimore, Washington, and Cincinnati, not to mention individual instances in other places, bear witness to the extent and earnestness of this feeling. Every day has brought fresh accessions to the list of those who decline to follow such leaders, and as the facts of this unfortunate business become more generally known, the list of those who distrust the leaders of the revolution inaugurated at New Orleans will grow apace.

Much was said at New Orleans and elsewhere about e Code question in connection with the Congress. ich gentlemen as have seen fit for reasons to withdraw om the Congress as at present organized, have been ccused of being unfriendly to the Code, and supporters f the New Code.

Philadelphia was the birth-place of the Code. There it was engrafted on the Constitution of the American Medical Association, and first offered as the creed of the profession in the United States, and there if anywhere, is its spirit a living spirit, and does its letter carry the force of law. And yet Philadelphia physicians were the first to take up arms against the New Orleans movement. But the question of Code was not in their minds. They well knew how adroitly and with what effect it had been used at the National Association, but when they met to record their objection to the Congress passing into the hands of its present leaders, the Code was never once mentioned; it was not thought of. The motives which influenced them, the causes which led them to decline to accept office in the Congress under its new organization, were of another and very different kind. Among other reasons these gentlemen withdrew from the Congress because—and chiefly—they distrusted the new management, and because the profession at large had been denied representation in that body.

When Dr. Leidy and Dr. Agnew, Dr. DaCosta and Dr. Stillé, Dr. Horatio Wood and Dr. Gross, and Dr. Parvin and their coadjutors met, their purpose was to withdraw from the Congress for the simple reason of distrust in its new management. They felt aggrieved at the behavior of the Association at New Orleans. They were dissatisfied with the action of the Committee at Chicago. And they went to record to this effect.

That the same feeling of distrust—not to use a stronger word—reaches to many other places, no observant man will deny. That it exists to such degree—that it exists at all, affords cause for the liveliest apprehension. That it will acquire such proportions as may lead the National Association to call a halt and undo some of the work it did in such unseemly haste at New Orleans, remains to be seen.

The conjuncture is certainly grave enough to make such action seasonable. And if wisdom united to courage and the charities direct and control the Association, it may still recover from the stab inflicted with its own hand at New Orleans, and bring the session of the International Congress in 1887 to a successful close. Otherwise the fate of the Association, no less than that of the Congress when it meets on American soil, is easily read.

The end of one will be disintegration and decay. That of the other will be mortifying failure. These are strong words, but sober withal.—*American Practitioner.*

The International Medical Congress, which is to convene in Washington, in 1887, it is to be feared will be a flat failure on account of the questions of medical politics and geography which have been raised by a few gentlemen who are anxious to play the rôle of Atlas to the medical world. Since the action of the committee at Chicago, scores of eminent physicians, whose names shed the brightest lustre on American medicine, living in Philadelphia, Boston, Baltimore, Louisville, and other large cities, have withdrawn and positively refuse to have anything to do with the matter. It now looks as though the Medical Congress will be like the play of Hamlet—with Hamlet left out. — *Indiana Medical Journal.*

The medical press, both in the United States and in England, has disapproved of the action of the American Medical Association in overthrowing the work of the Original Committee on the organization of the Congress. In fact, we are unable to mention at this time but one prominent journal which has sustained the Association in its course, and this is the journal owned by the Association and conducted solely in its interest. There seems to be no doubt in the minds of unbiassed and disinterested observers that the Association has been drawn into a position wholly untenable and unwarranted, and that its action was not only unwise but revolutionary. It is also evident to those who wish to see things in their true light, that the Association was drawn into this muddle by the action of but comparatively few of its members, whose motives, for their part in this affair, were not of the most disinterested character. The present outlook for the Congress admits of but one opinion, which is this, that the Association has committed a serious blunder and has shown itself incapable of reorganizing or conducting the Congress under its auspices. It seems clearly the duty of the Association to resign this matter into the hands of the general profession. The Association has so completely forfeited the confidence of the best minds of the pro-

Digitized by Google

fession, and has so antagonized the medical press of the country, that it seems a mistaken policy for it to attempt to proceed with the work of reorganization. The new Committee entrusted with this matter finds itself embarrassed and restricted in its actions from every direction. Many of its appointees have declined to serve under its administration, and it will also find that as it attempts to fill vacancies other vacancies will occur.

To make a long story short, we much doubt whether many physicians with self-respect will consent to accept the gifts of this Committee second-hand. No man with proper feelings desires to be put in a false position and to accept honors already declined by others. Facts are stubborn realities, and the sooner the present Committee on the Reorganization of the Congress realizes the doleful part it has been called upon by the Association to play and refuses to perform this part, the better will it be for the Association, for the Congress, and for themselves. The resignation of this Committee will relieve the present embarrassment of the affairs of the Congress. It will then be possible for the Association to reorganize this work, or else to abandon quietly the scheme of holding the Congress under its auspices. The latter policy would seem to be the most advisable from the present point of view.—*Maryland Medical Journal.*

Notwithstanding the efforts to prevent the successful meeting of the Congress, it will convene, and the combined forces of all the discontented "tribes of the East" will not prevent it, and those who refuse to serve on the committees will find that their places will be filled by representative men, who will forget personalities for the sake of doing honor to the cause of medicine.

We would call the attention of our professional brethren across the Atlantic to the fact that we have about sixty millions of people on this side, and among them thousands of better men in the medical profession than those who seek to interfere with the proper organization of the International Medical Congress, which is to meet in Washington in 1887. The doctors from abroad may rest assured that they will meet with a hearty welcome at the Congress, and that their associates in that august body will consist of the most accomplished gentlemen in the United States, and that they will in no way be disappointed in their expectations.—*Medical Herald* (Louisville).

The arrogance with which a few members of the profession in the cities of Philadelphia, Baltimore, Washington, and Boston, assume to constitute not only *the* profession of those cities, but also *the* representatives of all the respectability and science of the profession in the United States—the bitterness with which they assail the American Medical Association—and the odium they attempt to cast upon the representatives from each State, chosen by the Association to constitute a part of the Committee on Organization of the Congress, through their chosen organs, make it necessary to analyze this seemingly heterogeneous mixture of arrogance, bitterness, and misrepresentation, to lay bare its true animus, that if any important mistakes have been made the medical world may see clearly what the mistakes were and *who made them.—The Journal of the American Medical Association.*

Those who have looked forward to taking part in the next International Medical Congress, and have counted perhaps on making personal experience of that friendliness and hospitality of which every English doctor who has yet crossed the Atlantic has brought back such golden report—yes, and not only those, but every practitioner to whom the reputation of his profession is dear—will have read with intense surprise, if not distress, the intelligence we published last week, that the Washington Congress is in imminent danger of falling through. We are sorry to announce that our worst anticipations are in process of realization. The leading practitioners of Philadelphia, many of whom were to hold high office in the Congress, according to the list distributed by Dr. Billings some months ago, met together on the 29th ultimo, and decided that, as the changes recently effected in the preliminary organization and rules for the International Medical Congress of 1887 "are inconsistent with the original plan, and detrimental to the interests of the medical profession in America, and of the International Medical Congress," they would decline "to hold any office whatsoever in connection with the said Congress as now proposed to be organized." This resolution was signed by thirty of the most distinguished practitioners in Philadelphia, including men like Weir Mitchell, Horatio Wood, Roberts Bartholow, Da Costa, Duhring, Goodell, Minis Hays, Leidy, Pepper, W. Osler, Stillé, Tyson, and Yandell. We hear that a similar movement is on foot in Boston, and that it is quite likely that the most distinguished practitioners in that hub of the universe will follow the lead of their Philadelphia *confrères.* And as some of the leading New York men, including Dr. Jacobi and Dr. Lefferts, who were to have presided over sections, have already been deposed from their places as adherents of the New Code; while Dr. Bowditch, the most respected physician of Massachusetts, has been struck off the list of vice-presidents for his sympathy with that party, it must be admitted that the *New York Medical Journal* is probably right in describing the outlook for the Congress as "gloomy." We can only hope that the sound sense for which our American cousins are so distinguished will prevail, and that the decisive action of the Philadelphia practitioners will rouse the mass of the profession in America to step in and to decide by overwhelming numbers before it is too late, that old controversies shall be sunk, that old ill-feeling shall be buried, and that no one shall be allowed to turn partisan spirit into a ladder for his own elevation at the expense of the reputation and good-fellowship of the profession to which he belongs.

We do not wish, and we hope no one on this side the Atlantic will attempt, to revive the memories of the celebrated dispute on the Codes. We believe that the late Dr. Panum, the lamented President of the Copenhagen Congress, distinctly insisted, when the invitation to America was accepted, that the Code question should not be raised; and we feel sure that a very large majority of English and Continental practitioners will refuse to cross the water if this understanding is not rigidly kept to. They will feel, too, that if they go to Washington they can only go as the guests of an undivided profession. A Congress from which the most distinguished representatives of American medicine were excluded, or had withdrawn, would not be worth going to as a scientific meeting, while the remembrance of the bitterness and heart-burnings which had attended its organization would rob its social distractions of all their charm. It would be like feasting with a man, while his

Digitized by Google

wife, unjustly divorced, stood in the street watching. We can assure our American readers that, in the present case, the best English sympathies will be with the wife. The men whom English visitors, if they go, will go to see and hear, are the very men who have been elbowed out of the Congress. The scientific success of a Congress does not depend on numbers, but on quality. The profession in America is, no doubt, rich in numbers, as well as in scientific activity, but it is not so rich that it can afford to play all Europe with only pawns on its side of the board.—*London Medical Times.*

YELLOW FEVER AND CHOLERA.—The Marine Hospital Bureau is informed that up to July 16th there have been twenty-four cases and four deaths from yellow fever at Havana.

The United States Consul at Barcelona, Spain, makes a report to the Marine Hospital Bureau of the number of cases and deaths from cholera in the infected districts of Spain from the beginning of its appearance, March 4th, to July 4th. There were 28,044 cases and 12,347 deaths.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.—Dr. F. Le Sieur Weir has resigned the Chair of Dermatology in this institution.

THE ALUMNI ASSOCIATION PRIZE OF THE COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.—This prize, of five hundred dollars, is open to the competition of alumni of the College, and will be awarded in May next for the best essay showing original research upon some medical subject.

THE BERLIN UNIVERSITY HYGIENIC INSTITUTE.—PROFESSOR KOCH commenced, on the 1st of this month, a monthly course of lectures on Bacteriology in the University Hygienic Institute. The arrangements of his new institute, to which the building formerly occupied by the Polytechnicum has been assigned, are not quite completed, but some of the laboratories are so far fitted up that Professor Koch can now deliver courses to the University, similar, though on a more extensive scale, to those arranged last autumn and winter for civil and military medical men. Professor Koch's official connection with the Imperial Board of Health has now ceased. He will now devote himself as Professor of the University, and Director of the new Hygienic Institute, to bacteriological study in connection with hygiene.—*British Medical Journal*, July 4, 1885.

THE COLORING OF PICKLES WITH COPPER.—By virtue of the power conferred upon him by law, the Commissioner of Health of Brooklyn has declared the practice of coloring pickles with copper, in any form, to be dangerous and detrimental to the public health, and has prohibited the selling, or having for sale, in Brooklyn, of pickles so colored.

NOTES AND QUERIES.

THE INTERNATIONAL MEDICAL CONGRESS.

To the Editor of THE MEDICAL NEWS.

SIR: Without intending, in the least, to censure the action of the special committee of the American Medical Association, which recently met at Chicago, I feel it to be incumbent upon me to resign the position which I hold as a member of the Council of Military and Naval Surgery and Medicine of the International Medical Congress, which was organized to assemble in Washington in 1887. The reasons which impel me to this step are: I was appointed to that position by the *Original Committee*, and as their action in organizing the Congress has been revised, and their appointments very largely annulled at the last meeting of the American Medical Association, I do not think I can, in justice to the committee from which I hold my appointment, longer continue my connection with the Congress as it is now organized. In withdrawing from the same, I now desire to state, as much as I oppose the action of what is known as the new Code party, and as heartily as I approve and endorse the Code of Ethics as adopted by the American Medical and American Surgical Associations, still I am thoroughly and entirely opposed to the introduction of any and all medico-political questions into the organization of purely scientific bodies such as the International Medical Congress. This furnishes another reason why I am unwilling to occupy any position which would seemingly indorse such action.

The Secretary-General, at whose hands I received my appointment, having resigned, and the gentleman selected to fill his vacancy declining to serve, leaves no one in position to whom I can address this communication. This must be my apology for intruding myself upon your journal.

I am, very respectfully,

C. H. MASTIN, M.D.

MOBILE, ALA., July 17, 1885.

PATHOLOGY OF THE LONDON HERBALIST.

"You know, sir, bad spirits means that the liver is out of order. The doctors gives you a deadly mineral pizen, which they calls blue pill, and it certainly do pizen 'em, but then you run the chance of being pizened yerself. You 've noticed the 'oles in a sheep's liver after it's cut up, 'aven't you? Well, them 'oles is caused by slugs, and 'uman bein's is infested just the same. So is awsiz (horses), bu' they don't never take no blue pill. Catch 'em! The doctors knows all about it, bless yer, but they don't talk so plain as me. *I* calls out-of-sort-ishness 'slugs in the liver,' and pizens 'em with three penn'rth of dandeloin tea, for which I charges thrippence. *They* calls it 'sluggishness of the liver,' and pizens 'em with a penn'rth of blue pill, for which they charges a guinea, and as often as not they pizens the patient too."—*London Cries*, 1885.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 21 TO JULY 27, 1885.

BELL, JOS., H, *Major and Surgeon.*—Died at Yonkers, N.Y., July 21, 1885.

MCDOUGALL, CHARLES, *Lieutenant-Colonel and Surgeon* (retired).—Died at Fairfield, Va., July 25, 1885.

STRONG, NORTON, *Captain and Assistant Surgeon.*—Ordered for temporary field duty with battalion Eighth Cavalry, at Hillsboro, New Mexico.—*S. O. 34, Headquarters District of New Mexico*, June 27, 1885.

EVERTS, EDWARD, *First Lieutenant and Assistant Surgeon.*—Ordered for duty as Post Surgeon, Benicia Barracks, California.—*Par. 3, S. O. 70, Department of California*, July 15, 1885.

WINN, C. K., *Captain and Assistant Surgeon.*—Ordered for duty at Benicia Arsenal, California.—*Par. 3, S. O. 70, Department of California*, July 15, 1885. (*Modified par. 2, S. O. 68, S. O. Department of California.*)

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

VOL. XLVII. SATURDAY, AUGUST 8, 1885. No. 6.

ORIGINAL LECTURES.

A MODIFIED OPERATION FOR CYSTOCELE.

Remarks before the Cincinnati Obstetric Society.

BY THADDEUS A. REAMY, M.D.

(Specially reported for THE MEDICAL NEWS,

By James M. French, M.D.)

GENTLEMEN: Contrary to the custom of the Society, I will make a verbal instead of a written presentation of the subject assigned me. I do not desire to offer a new operation, but only a modification of the operations already proposed for the relief of cystocele. I will not go into the causes of cystocele any further than to bring forward the facts necessary to explain the operation proposed.

It is well known that Scanzoni advocated the doctrine that cystocele may exist primarily without a prolapsus of the anterior wall of the vagina or other conditions of the vagina to cause it, the vaginal prolapsus being secondary and dependent upon the cystocele. He supposes that in these cases there is spasm of the fibres of the body of the bladder, while the neck is quiet—the urine thus forced to remain in the fundus, dilating it and producing the cystocele. This view is adopted by many, but is discarded by most authors.

Cystocele is rarely found in women who have not borne children. It is rarely disassociated with deformity of the vagina. The walls of the vagina in such cases have been altered in their conditions, in their relations, and in their thickness. In short, we have a prolapsus, and this is especially the case if there is any great degree of cystocele. The bladder is to a great degree held in its position by the firmness and supporting power of the vaginal walls, the relations being intimate, and so long as the vagina maintains its proper strength, its proper size and relations, there can be little or no cystocele. It is now stoutly denied, especially by my friend, Dr. Frank P. Foster, of New York, that the vagina or perineum have anything to do in supporting the uterus. Be this as it may, it is clear that loss of the perineum and associate deformity of the vagina, play a very important rôle in cystocele, and this fact must be considered both in a study of causes and devising methods of treatment. Of course, we all know that generally in these cases one of the most troublesome symptoms is irritability of the bladder, although even this is held in question by some. I need not dwell longer on this part of the subject, as I am speaking to practitioners, not to students or beginners.

Now, the question is, What can be done for the relief of this condition? and it was to illustrate the operation for this that I brought the subject before you this evening. We know that the first and simplest methods which are employed are those which aim to hold the bladder in place by pessaries, etc. Dr. Skene has devised a pessary which is one of the very best within my knowledge. There are many others with which, of course, you are familiar. In simple cases these devices do very well indeed; but even in such cases they seldom accomplish a cure, operative measures becoming a necessity. I am well aware of the fact that in any surgical measures yet devised, we have not in all cases, even permanent relief, much less cure. Indeed there are many who deny that permanent relief is obtained by any surgical or other measures in any case. With these views I cannot agree. My own clinical experience fully warrants me in dissenting. In almost every case where there is not serious uterine prolapsus, as well as prolapsus of the vagina and bladder, permanent relief may be expected provided the surgery be well done. But of course in cases where there is perineal loss, with vaginal deformity and prolapse, the operation for cystocele proper must, in every instance, be associated with or supplemented by perineorrhaphy and, if necessary, colporrhaphy. The fallacies which are held by so many on this subject, in my judgment, have their origin chiefly in the erroneous conclusion that because it is difficult, and in many cases impossible to cure a uterine prolapsus, it is, therefore, impossible to cure a vaginal prolapsus, forgetting that the former frequently exists for a time without the latter; although it must be recognized by all that sooner or later the uterine displacement will generally follow as an inevitable result of the dragging of that organ by the prolapsed vagina and bladder. It is true the weight of the vagina is not great, though under such circumstances it is generally increased above normal, for subinvolution of the vagina is almost uniformly present; nevertheless the weight is quite sufficient to cause the evil. It is not the amount of weight, but the direction and character of the dragging that finally accomplish the bad results. I may as well here as elsewhere declare my belief that, in addition to this dragging upon the uterus, there is the negative influence: absence of such support as the normal vagina gives to the uterus. Unpopular as this view is at the present day, I still believe that this support is not wholly a myth, although, in former time, it has unquestionably been overestimated.

But as to surgical methods, I shall only refer to those proposed by Dieffenbach, Sims, and Emmet, though there are many others of merit. The method of Dieffenbach, as all know, consists of an elliptical denudation from the anterior vaginal wall, closing the edges by suture. When well done, union is firm, and in simple and mild cases the result is satisfactory. But in bad cases the extent of denudation necessary causes deformity of the vagina when the cure is effected. Sims's method consists of an elliptical denudation as in the method of Dieffenbach, but the whole surface is not denuded, only a narrow strip, forming the ellipse, the centre being undenuded thus (see blackboard). There are two important objections to this method. First, at

Digitized by Google

the middle of the ellipse especially, so great is the tension upon the sutures, that they are liable to cut out at once. Secondly, when union is secured, the paths of denudation and of union are so narrow that in a short time the newly united tissue will have stretched under the tension to which it must be subjected, and the benefits of the operation are lost. These are just the same objections which exist against both Sims's and Emmet's operations for prolapsus of the posterior vaginal wall. The principles are the same, no matter which wall is to be treated.

For Emmet's latest operations, I must refer you to the figures in his book.[1] It will be seen that the lines of denudation follow no geometrical rules, and cannot be described. Two-thirds of the figure next to the uterus are in form not unlike the ellipse of Sims or Dieffenbach. The remaining portion is crescent-shaped with its concavity toward the urethra. These lines are approximated and union occurs. The old objections again arise. First, there is a portion in the centre undenuded, so that should union occur the tissues must yield in time. Second, as this distinguished author himself confesses, union at the triangular angles is difficult to obtain, a second operation often being necessary.

This last objection, Dr. Emmet thinks, he has now succeeded in overcoming by another modification which I do not detain you to describe, as you have access to his better description in his valuable text-book. It is sufficient for my purpose to say that in the modified operation one crescentic line of denudation crosses the base of the urethra with its convexity toward the meatus. Another similar line crosses the upper portion of the vagina with its concavity toward the uterus. This author, with the candor for which he has such just reputation, admits that he has tested the method in but few cases and cannot yet tell how it will stand the test of clinical experience. I must state my objection that this method also leaves the central portion of mucous membrane undenuded, so that it seems probable that the parts will yield.

As to my own method, I have followed it in public hospitals and in private practice for eight years, with very satisfactory results in favorable cases. I think it has some important advantages.

For the operation, the patient is placed in the extreme lithotomy position, an assistant holding each lower extremity, the posterior vaginal wall held back by Sims's speculum. The tissues are caught up by a small double-toothed tenaculum forceps, and the cutting is done with long scissors, sharp-pointed, curved on the flat—the same as used in perineorrhaphy.

A constant stream of water at 100° F. is allowed to play on the field of denudation, the water being carbolized. This controls hemorrhage and keeps the field clear.

I beg to refer you to the imperfect figure which I now draw on the blackboard, which explains the direction and extent of denudation, also the method of suturing and closing.

Fig. 1 illustrates practically the direction of the denudation, but of course this will vary with the amount of cystocele you are dealing with and the amount of tissue you desire to remove. The denudation is also modified in width or length as each case requires. If you desire to cut deeply, you must remember to avoid wounding the ureters as you denude

FIG. 1. FIG. 2.

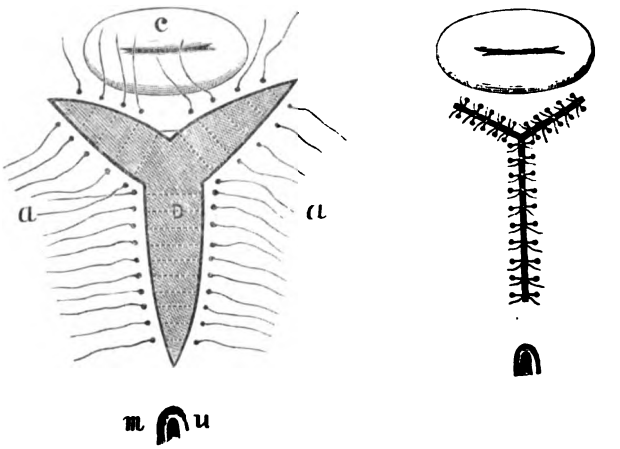

FIG. 1.—D. Denuded surface. The lines of denudation are sharply defined, so that when the sutures are tightened they shoulder against each other, and firm union by first intention is secured. Ordinarily no cicatricial tissue is found in the line of union.

a. This suture approximates the three angles.

c. Cervix.

m u. Meatus urinarius.

FIG. 2.—Position of parts after sutures are tightened so as to approximate the edges bounding the field of denudation. Sutures tied.

the lateral branches. There is, however, substantially no danger of this unless you carry the arms some distance out beyond the cervix. I have never encountered accident, but theoretically the danger does exist. I will call your attention later to the importance of carrying the denudation deep, and sometimes even into the bladder.

With regard to the position of the ureters, you will see by looking at plate No. 3, by Savage, that the relation is given. The bladder-wall is cut away, showing the relation of the cervix to the entrance of the ureters into the bladder, and it shows you the direction followed by the ureters as they enter.

The inquiry as to results might be stated as Thomas puts it. He says it is not material what direction the denudation may take, provided you get rid of sufficient redundant tissue (or words to that effect), and take up the pouch that is present, for it will contract from all directions. But you can readily see that the uterus is one fixed point, the meatus another, and the greatest amount of redundant tissue is situated just forward of the cervix. Now you can see a step further, that if you carry the arms of your denudation on either side of the cervix, the direction of the contraction will be directly in harmony with the original construction of the parts, and that the contraction, if you get union, will be in the very direction in which you desire to get support. Further, in this method the tissues can be safely subjected to greater traction than they can bear in any other method of procedure. In the clinical use of the

[1] Principles and Practice of Gynecology, third edition, pages 362–3.

Digitized by Google

method you will find that you do not have to denude so large a field in order to get sufficient contraction, or, rather, no one path of denudation is so wide.

Now a word with regard to the depth of the denudation. As you come down toward the urethra, you can denude very deeply, but it is not necessary to go so deep there, as it is further up towards the bifurcation of the denudation. Here, however, if you simply take off the mucous membrane, and do not go through the muscular tissues of the vagina into the cellular tissue between vagina and bladder, the operation will fail, and because you can denude so deeply with safety by this plan is one of its chief advantages. In two cases in which I desired to cut deep, I have opened the bladder and formed a vesico-vaginal fistula, but I closed it up at once with the sutures of the operation for cystocele, and nothing untoward occurred. Denude deeply, for the more deeply within limits the more certain you will be to get good results. As already stated, at the upper extremities of the denudation it is better not to go too deeply, on account of the ureters; but that danger, as already stated, I do not regard as great.

The sutures are placed in much the same manner as in the other operations, only it is important that they be placed close together. I usually put as many as eight to the linear inch of the denudation. It is important that the suture marked "a" be placed as represented in the drawing. This is for the purpose of drawing the three arms of the Y together, when the stitch is drawn tight. The consequence is that the tissue is pulled forward and backward and the uterus being more fixed than the other parts, the tissue is put upon a stretch transversely also. It is immaterial whether the threads show on the denuded surface or simply split the tissues in the middle of the denuded surface. Even if the suture should go into the bladder, it will do no harm. It is important to get the border surfaces united perfectly by first intention.

The kind of suture I am using is the so-called silk worm gut, out of which fish-lines are made. It is really made of the intestines of a fish, it is an animal ligature, and you can with ease render it perfectly aseptic. It is strong enough for any purpose of this sort. You can draw it with almost your entire strength without breaking it. It is prepared for use by cutting the kinked ends off with the scissors, and throwing the rest into a carbolized solution—a ten or fifteen per cent. solution in warm water, and in a half hour it is ready for use. Tie two or three knots, or it may come undone, but you may cut the ends short or long as you please. Its advantages are: first, it is very smooth; you can arm the needle with it directly and it will not kink like a silver wire. Second, it has strength enough for any operation of this kind, including trachelorrhaphy. Third, if you render it antiseptic, my observation has been that no more suppuration will follow than follows silver wire. In this I agree with the opinion of my friend, Dr. Sutton, who has used this suture many times more than I have and who first advised me to employ it. Fourth, although the ligature gets soft enough in the preparation for you to tie it with ease, yet it gets no softer, although permitted to remain in the tissues three or four weeks, thus affording support as to position of tissues equal to that of silver wire. Fifth, although an animal ligature, it is not absorbed, and remains like a wire for weeks. Sixth, you can leave the cut ends in the vagina, for they will not jag the tissues, and even a No. 28 wire will jag if the ends are cut short.

After the operation the patient must be kept in bed and a self-retaining catheter kept in the bladder, constantly, for eight or ten days until union is complete. This, I regard as essential, since the distention of the bladder, which may not prevent union, will nevertheless prevent the union from occurring with the field of the operation in the contracted state so favorable to good results. These remarks will impress you as all the more important, if you recall my recommendation always to carry the denudation through the vaginal wall, at least near the centre.

I have operated after the method proposed in fifty cases, and think my experience warrants the claim that it possesses the following advantages:

1. Simplicity, ease of execution.

2. Less width of denudation is required at any given point, in order to secure the necessary contraction after closure than in other methods.

3. The deep denudation necessary to cure, in all cases, can be done by this method with greater safety.

4. Since tension upon any one line of the operation after union is less than after other methods, and since the deep denudation causes firm union, the good results are likely to be more permanent.

5. After cure, the vaginal orifice and entire anterior wall of the vagina will conform more perfectly to the original.

In closing the discussion which followed the above, DR. REAMY said: I shall have to dismiss the question that has been raised concerning the propriety of making a perineorrhaphy or a colporrhaphy posterior, by simply calling your attention to the fact, in the beginning of my remarks, I stated that what I should say had reference only to the operation for cystocele, without any of the complications, except prolapse of the exterior wall of the bladder, and I referred to the other complications only so far as to be understood. I have frequently made my operation, however, in connection with perineorrhaphy and posterior elytrorrhaphy. Of course, no man would make this operation alone except for pure cystocele, or cystocele with prolapse of the anterior vaginal wall, which is also cured by the operation. No treatment is complete unless you restore the vagina. It is advisable, however, when the posterior operation is to be done, and plenty of time is allotted to the operator, and where he can control the patient, to make the operation on the anterior wall first; then, as soon as the patient has recovered, and before she is out of bed, to make that on the posterior wall.

With reference to the method of Dieffenbach, for which one of the speakers has expressed preference, with Emmet's modification, if we take out sufficient tissue, in the elliptical form, it does well, provided the case is an uncomplicated one. To show that it is defective, however, we have but to consider what will be the shape of the cicatrix resulting from the removal of an elliptical portion of mucous membrane in a bad case demanding extensive denudation. Will not every one agree that it is the highest type of gynecological skill to restore deformed parts as nearly as possible to their natural condition? In Dieffenbach's operation what do you do? You draw the edges of an elliptical

Digitized by Google

denudation together, and necessarily deform the vagina. The method disregards the form of the wall, and does not regard the constriction of the vagina where it goes forward to join the bladder wall. It makes a flat, straight surface. In addition to this it removes so broad a surface that to go deep is dangerous. The prime advantage of the operation proposed, on the other hand, is its simplicity, and the small amount of tissue removed. Still, if the two arms of the denudation are placed side by side, it will be seen that the amount of tissue removed is considerable. The apex of the undenuded surface between the arms is fixed to the anterior uterine wall, and the result is practically the same as if a much larger surface were denuded. No undenuded surface is covered up. The angles are so easily brought perfectly together that union readily occurs. The rule is to make the denudation wide or narrow, according to the degree of cystocele, and to carry the lower arm down far or only a short distance, according as urethrocele is present or absent.

In reply to the statement of a gentleman who thinks the proposed operation the same as that of a distinguished author named, except that the directions of the triangles are reversed, I remark that he is mistaken. First, the arms of the denudation are in different relations. Second, the central denudation in my operation, which runs longitudinally with the bladder, is complete—no undenuded portion—edge to edge. Finally, in this connection, it is eight years since my method was devised and done in a public hospital.

ORIGINAL ARTICLES.

COCAINE IN THE TREATMENT OF THE OPIUM HABIT.[1]

BY J. T. WHITTAKER, M.D.,
PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE IN THE MEDICAL COLLEGE OF OHIO, CINCINNATI.

THE remarks which I beg to offer to the Academy are based upon the treatment of two bad cases of the opium habit, one treated without, and one with, cocaine, whereby I had the opportunity of contrasting the effects. This contrast was made all the more striking from the fact that the case treated with cocaine had been on a previous occasion treated without it, the conditions on the two occasions being about the same.

My first opiophagist was a successful merchant who had fallen into the habit after prolonged use of the drug prescribed by his attending physician for relief of neuralgic pains. I shall not run the risk of wearying the Academy with details. This individual awoke one morning hemiplegic and hemianæsthetic, and it was the fright occasioned by these symptoms that led him to send for a physician. I found him a victim of confirmed morphinism. He had no less than five hypodermatic syringes in his various pockets (one in each coat-tail pocket), and was using the drug in this way in the quantity of fifteen grains per day. I undertook to cut the patient off at once, keeping him under close surveillance night and day, but symptoms of collapse with colliquative diarrhœa set in on the same evening, so that I was compelled to resort to the use of opium with large quantities of brandy to save his life.

The treatment of this case was a three weeks' siege of more or less constant attendance on my part, and vigilance on the part of the nurses. The victim of delirium tremens could scarcely have suffered more intense torture of mind. At last, at the end of about three weeks, the patient was able to walk about, and in another week to take daily rides; but there was still occasional insomnia, much mental distress manifested in a whining, whimpering, scolding way, and there remained occasional attacks of irregular shooting neuralgic pains in the arms and legs, which were quite defiant to all kinds of treatment. The pains seemed always more imaginary than real, but they formed the basis of complaint. At last the wife of the patient, who was much of a hysterical turn herself, concluded to take him to the faith-cure in a distant city. A stay of a week seemed to be of so much value to several members of the family as to justify the importation of the establishment to this city *en masse*. This was accordingly done, and thus was a branch of this ever-recurring temple of credulity set up with us. The original importers of it finding it growing a too expensive luxury, broke with it finally altogether, and rapidly increasing failures in treatment soon broke it up. But whether from pride, or lapse of time, or, what is more probable, from increasing general health after release from the opium, the patient continued to improve, and remains, I am informed, in a fair condition of health after the lapse of a year.

My second patient was a young woman of good physique, aged about twenty-five, who had likewise been introduced to morphinism by use of the drug in relief of an obstinate neuralgia—at least this was her story. Besides this physical there were psychical reasons in her situation in life which made her a more easy victim to the allurements of the drug. This patient, according to her own statement, had taken never more than three to five grains per day, and always by the mouth. After several ineffectual efforts to stop the use of it at her own house, she put herself under absolute control at the Good Samaritan Hospital. The morphia was withdrawn at once. Two nurses were detailed to watch this patient by night and day. The suffering that set in by the end of the second day was extreme. Quinine was given freely, and chloral at night, but without effect. There was no sleep throughout the night. On the next day, for a profuse diarrhœa, bismuth was ordered in full doses, and for the total anorexia the simple tincture of cinchona. At night atropia was administered hypodermatically with the statement, for its psychical effect, that the solution contained morphia The atropia produced no sleep whatever and by midnight the patient had become desperate. She pleaded for morphia continuously. The nurses, however, remained firm in their refusal. Forty grains of the bromide of potassium were then administered, but there was still no relief. The patient now tried a ruse which nearly proved successful. She pretended to fall asleep, whereupon the nurses, wearied by the watch of the previous night, fell into

[1] Being the remarks made in the opening of the discussion of the subject at the Cincinnati Academy of Medicine, June 29, 1885.

Digitized by Google

a real deep sleep. The patient now arose and began a search for her clothes, which had been secreted; failing to find them, she tied her bed-clothing by the ends and by means of this improvised rope slid down to the ground, ran across the street and was found by a passing policeman standing in her night clothes pounding upon the door of a neighboring drug store to awaken the clerk. By the time the hospital authorities became aware of her escape the officer had returned the patient to the gates of the house. It was then thought best to practise gradual withdrawal of the drug, and this treatment was effectually carried out, but not without great distress, in the course of two weeks.

This patient persisted in refraining from opium for three years, when, during an attack of pneumonia, her physician in a distant city prescribed it in relief of her cough, and started her, according to her own account, anew in the habit. So soon as she felt herself thoroughly addicted to the drug she came back to this city to make the effort to desist from its use. She was taking now but two grains a day, one grain morning and evening, but she had the manner and bearing of a confirmed *habitué*. She made two distinct efforts to break the habit at her house, during which time she took large doses of the bromides, of chloral (two drachms in one night), of atropia, of the fluid extract of coca, and, on one occasion, to secure the only sleep she had, she inhaled chloroform for an hour. These statements were confirmed by a friend who had procured the remedies, as also by the presence of the drugs in the room.

Two weeks ago she reëntered the hospital under the promise which I had to make that I would prevent any undue suffering—anything that approached her previous experience—by the use of a sufficient quantity of morphia. Upon admission she was given ten drops of a four per cent. solution of the muriate of cocaine every two hours, but as this remedy produced no perceptible effect by night beyond a slight flushing of the face, she was allowed an injection of morphia, one-fourth of a grain. She rested fairly, but slept none that night, and on the following morning began to show the usual symptoms of abstinence. A cup of strong black coffee braced her for a time, but by ten o'clock she was in a state of great nervous unrest. I now gave her hypodermatically ten drops of a ten per cent. solution of cocaine. The effect was very striking; within five minutes the agitation subsided, the patient seated herself in a chair—she had been walking the floor wringing her hands—and with a flushed face and brightening eyes she expressed the immediate relief she felt, and began quite an animated conversation. This state of exhilaration was continued for an hour and a half, at the end of which time the old nervous symptoms began to assert themselves, and in two hours she was as bad as before.

Not to protract too much this history of a single case, I may state that four such doses were taken in the next twenty-four hours, two more than I had intended, always with the same immediate effect, but each time of shorter duration.

After the last two injections she complained of very unpleasant sensations in the chest—sensations of oppression—with a general feeling of distress, to such degree that she declared she would not have another injection. To this proposition I readily assented, as there seemed to be some failure in the action of the heart. These unpleasant sensations disappeared under the use of coffee and brandy, but the patient was by no means as comfortable as she had been after a dose of morphia. Except the quarter of a grain referred to, no morphia had now been taken for seventy-two hours. I left under the impression that the victory had been gained, but only to learn in the course of the same day that the patient, after some altercation with one of the attendants, had returned to her home. She sent for me in the afternoon and informed me that she had taken half a grain of morphia. I thereupon withdrew from the case.

Four days later I was again summoned to her house on another pretext. I found the patient entirely free from the influence of opium, so far as I could judge, and was called to prescribe for a severe diarrhœa from which she always suffered for a time when the drug was discontinued. She had not touched it since, she said, with an air of pride, and after the night's sleep which the half a grain had secured, she had really had no craving for it which she could not resist. I visited her daily for ten days thereafter, during which time she rapidly regained her color, increased her weight, and recovered her natural buoyancy of spirits. She was herself persuaded—and this was the opinion of her friends—that she had gained such an easy victory by the use of the injections of cocaine. Therefore I give the case for what it is worth. Perhaps it may be an incentive to trial of its value in cases where testimony may be more carefully weighed. From my own observations, I am convinced that cocaine alone is not a perfect antidote or substitute for morphia, but I feel sure that a faithful trial of it will show it to be the best auxiliary we have.

With the indulgence of the Academy, I will now venture to make some remarks upon the opium habit in general, more especially regarding its diagnosis, the tolerance which, as is universally known, is gradually established, the evils which finally ensue, and the most approved means of treatment in our possession.

For the more pronounced cases of this morbid condition we must take a passing glance at the Orient, where the opium habit prevails at all times, we might say, as an epidemic. The law which forbids the use of alcohol is largely responsible for the universal use of opium in Mohammedan lands. Some form or other of nerve narcotic seems to have become necessary to man, and this is the form which has substituted all others in the East. Then, other forms of religion, as that of the Buddhists, for example, impose upon their followers long periods of fasting and opium is taken to relieve the cravings of hunger. It is estimated that one hundred millions of Chinese are opium smokers. But the influence which is far more powerful in the East than either hunger or religion is the belief that opium has aphrodisiac properties. It is strange that this drug has come to be credited with

Digitized by Google

such effects when if there is any thing definitely settled regarding it the very reverse is true, as is seen among all its *habitués* Some idea of the extent of the use of opium in India may be gathered from the fact that nearly two and a half millions of dollars are paid for license fees alone, many of the dealers in Calcutta, like the beer brewers in our own country, owning seventeen shops apiece. Richards made a series of extensive observations upon the opium eaters of India, 143 of whom had taken the drug from 10 to 20 years, 62 from 20 to 30 years, and 18 over 30 years, in quantities varying from two to forty-six grains per day. He remarks that when used in moderate quantity it produces no perceptible effects except anaphrodisia, and as regards crime its *habitués* compare very favorably with those of alcohol, as opium eaters are, as a rule, a law-abiding class. Further, that it contributes but very slightly to insanity, as the opium eaters thus affected constitute but 0 0007 of the population. Used in excess, it begets the same physical and psychical degradation noticed in other races. But the opium habit is unfortunately not confined to the followers of Mohamet, nor to the lands of the East. It has found its way extensively throughout Europe and is increasing every day with us. Allen Williams makes the astonishing statement in the British Encyclopædia that quite a million people in the United States are addicted to this habit and that though Chinese immigration has been brought to a stand, the number of *habitués* continues to increase. In Michigan one ounce per week is, he says, the average quantity used by each opiophagist. This statement would seem to bear the imprint of exaggeration if the physician may judge from his own observation, but it is contended by those who stand behind the scenes, or rather counters of our drug stores, that not all the truth is told. The victims who do become the clients of physicians, maintain that they have been introduced to the use of the drug in relief of pain. Physicians' prescriptions are filled and refilled continuously long after medical attendance has ceased or the cause for the use of the drug has disappeared. The victims of tabes, cancer, tuberculosis in advanced form, and other incurable diseases, furnish a certain but by no means the largest contingent of cases. The great percentage of cases is furnished by the individuals of neurotic temperament, of weak will power, or unfortunate surroundings.

The tolerance which is begotten to the use of opium has been known ever since the drug was used in medicine, which period antedates by many centuries the birth of Christ. We become familiar with excessive quantities in the treatment of peritonitis, tetanus, chole- and nephro lithiasis, mania, etc., but these quantities are equalled, if not exceeded by opium *habitués*. Thus Taylor reports that the average quantity of the English opiophagist is from 3 to 8 ounces of laudanum per day. Coleridge is said to have taken a pint a day, and it is reported of De Quincy that he took a quart a day. Disregarding these statements as lacking authentic support, I may cite the case reported by Husemann of a woman affected with carcinoma uteri who took at least 20 grains of morphia a day, and a similar case by Credé, whose patient took 52 grains a day. Jul. Beer reports the case of a woman affected with metritis and fistula, who often took 24 grains a day and who consumed more than a pound and a half of the acetate of morphia in the course of three years. Burkhart mentions a case of morphinism where the victim after long internal use commenced its administration subcutaneously with 30 grains, and later increased the dose. But the most famous case is that recorded by Albin Eder in the *Oesterreich Zeitschr. für prakt. Heilk.*, No. 33, 1864, of a preacher who had used the drug for eleven years. He commenced with the tincture, which he gradually increased to one ounce a day, then used opium in substance in doses increased from 18 to 160 grains a day. Thereupon he began the use of morphia at the rate of seven grains every 9 hours, which he increased some months later to 27, and finally to 45 grains.

When the condition known as morphinism is reached its signs are plain and easily discerned, but where but small quantities are taken there may be no outward manifestations of the vice at all. A growing irritability of temper, a spirit of fault-finding, a fretfulness over trifles, or a temporary exhilaration with its reaction of depression, an increase followed by a blunting of the usual sensitiveness, or a lack of delicacy and refinement, may be remarked by the closest relatives, but not perhaps in any suspected connection with the habit. There is no doubt that unless discovered by accident the great majority of these cases remain unrecognized until the more pronounced signs of the condition supervene with the gradually increased dose. Walle, of Hanover, who suffered in his own person, speaks of this as the first stage or phase of the condition. With the occurrence of the second stage ensue more distinctive physical and psychical signs which are easily recognized when once the suspicion of the physician is aroused. The body is usually bent, the gait is sluggish, all movements are slow and more or less uncertain; there are tremor of the hands, and muscular twitchings in various parts of the body. The face is pale or wears a yellowish or greenish cast, the expression is dull and heavy. The eyes are half closed, with slow drooping of the lids, to be often suddenly lifted and again to droop. The eyelids are red from frequent friction with the hands, which are also often brushed across the forehead. The pupils are contracted and irresponsive. There is more or less constant sniffling of the nose with occasional forcible sneezing and the discharge of a thin watery mucus. Characteristic changes are always to be observed in the teeth. This singular fact, first remarked by Combes, was communicated to the Paris Academy, April 28, 1885, by Rochard. It is noticed that so soon as the body becomes saturated with morphia the enamel of the opposed surfaces of the molar teeth begins to suffer. The process of decay next invades the premolars, and lastly the canine teeth to such degree as to give them a cup-shaped form. Caries of this kind being unattended with periostitis is not painful, though it runs a rapid course. Yawning, long, deep, and more frequent and protracted than when waking from sleep, is a quite characteristic sign. There is more or less complete anorexia with especial aversion to meats; the taste is

Digitized by Google

blunted or lost; the tongue is coated; eructations, vomiting, and borborygmus are frequent; There is constipation or alternate diarrhœa, with, in the former case, unusually long stay and straining at stool, and the occasional discharge of mucus and blood. The skin sweats profusely after the slightest exercise or after any disturbance of the emotions. The urine in consequence becomes scant and dark; albuminuria or glycosuria may develop (Loewinstein); and the bladder becomes irritable when not quieted by the immediate effects of the drug. Amenorrhœa is common in the female and aspermatism in the male. The sexual functions, though slightly stimulated in their cerebral aspects at first, become gradually more and more obtunded until they are entirely lost, both as regards desire with pleasure and capacity. The average number of children of the opiophagist is reduced to 1.11 after eleven years of married life (Richards).

With these physical are associated psychical traits equally characteristic. There is the same languor of mind as of body, expressed in the general lack of interest or inability to concentrate the attention. It is plain to see that the intellectual and moral tone of the individual is reduced to a lower plane. The opiophagist grows neglectful of family duties and social obligations, becomes careless and untidy in dress, inconsiderate and indifferent to the opinions and regard of others, entirely preoccupied with his own sensations. The flashes of consciousness or wit which in highly sensitive, poetic, or overwrought imaginations may even exhibit the scintillations of genius, become more and more fitful and further apart, to leave the gloom of life more palpable and permanent than before. It is easy to stray from the rigid requirements of science to the airy realms of rhetoric in describing, or trying to illustrate this sombre state and still keep within the sober bounds of truth.

The last stage of morphinism is reached when the stage of apathy gives place to the stage of excitement. Such tolerance has now been established that appalling doses are required to maintain the effects. The gait has become more and more impaired. Lewin speaks of a case where it became necessary to use a cane, and there are on record cases which presented the symptoms of ataxia. The main cause of the excitement is the exhaustion produced by loss of sleep, which has now become impossible under whatever dose. Whatever interrupted sleep is secured leaves no sense of rest or refreshment. The bed is found tossed about in the morning with the jactitations of the night. Under this condition the expression grows more and more anxious and excited, the face is haggard, the eyes sunken and shining, there are outbursts of genuine mania, or delirium occurs with hallucinations under which the patient sinks with a slow marasmus, or with a condition of profound melancholy whose end may be precipitated by suicide.

There is, probably, no victim to the opium habit in excess that has not at some time made some effort to discontinue its use, as there is no *habitué* to any, even the most innocent quantity, who does not look forward to the time when he will abandon it altogether. The class of people who become addicted to opium, as to any vice, is precisely the class that abound the most in good intentions. But the desired result is rarely accomplished. The confirmed opium eater can never desist unaided, and cannot be always rescued permanently even with every assistance. Every failure in the attempt breaks anew the force of the will, or what fragments of it are left, until at last the victim surrenders with the resignation of despair. Recovery is, then, only possible by the substitution of the will of others. Absolute control, with perfect isolation, is therefore a *sine qua non* in the treatment of most of these cases. It becomes, then, a question whether or not the drug is to be suddenly withdrawn. The authorities are about equally divided upon this question, which had best be left to the judgment of the practitioner in the individual case; so much will depend in solving it upon the amount which has been taken, and the temperament and constitution of the individual patient. A gradual withdrawal entails much less severe, but more prolonged, suffering, and patients are much more willing to undertake a siege of this kind than to storm the citadel at once. In private practice, in the great majority of cases, there will be no assent on the part of the patient to any kind of treatment which does not promise decided assistance in the way of substitution, or so-called antidote, from the start. Patients who submit readily to sudden withdrawal, without conditions, and experience speedy cures, are cases of deception. They have the drug secreted about them, or obtain it from sympathizing attendants. Druggists, like saloon-keepers, who are very lenient in their supplies, easily overcome their scruples with the reflection that others will comply if they refuse.

Thus arises the question of an antidote. It is quite superfluous to mention here more than the names of the drugs which have enjoyed this reputation from time to time. Atropin, pilocarpin, muscarin, each possesses properties antagonistic to some of the effects of opium; and are hence, strictly speaking, antidotes in cases of acute poisoning by the drug. But none of these agents antagonizes the cerebral effects of opium, which constitute the chief suffering of the opium devotee. Chloral and chloroform, hyoscyamus, conium, etc., may force a sleep of a few hours, to leave the patient more wretched than before. The various bromides fail of even temporary relief. Strychnia, quinia or cinchona, capsicum, agents whose virtues have been vaunted in the treatment of morphinism, owe their reputation rather to transient indications they may meet than to any neutralization of effects. So far as real relief of the condition is concerned, none of the remedies equals in value prolonged warm baths, gentle friction of the surface, or the administration of a cup of strong, black coffee. I do not speak of the multitude of secret antidotes sold at large, and used in so-called "retreats." What virtue they possess is wholly due to opium. Large quantities of morphia are now exported to China for the cure of the opium habit. The powders are mixed with rice, and taken at gradually increasing intervals.

The true antidotes of opium being thus of so little use, search has been made in a different direction to find, not an antidote, but a substitute; and this investigation has been rewarded, to some extent, with

Digitized by Google

the discovery of the properties of coca, a drug which, while it does possess some antidotal qualities—mydriasis, for instance—possesses more analogous properties, especially as regards its action on the brain.

Coca, or more properly cuca, is a remedy comparatively new in materia medica, but its popular use is as old, so far as we know, as opium itself. In comparatively modern times the wood of the coca tree, as one of the red woods, has become an article of extensive commerce on account of its color; but, long before this period, the leaves were found in common use as a masticatory by the natives of various parts of South America. The tree grows spontaneously on the east of the Andes, but has been successfully cultivated in Bolivia. It is estimated that eight millions of people chew the leaves of cuca, which they carry in leathern pouches mixed with the ash of other plants, which alkali softens the leaves for easier mastication. Two to three ounces of the leaves constitute the average daily quantity for each individual; but this quantity is exceeded when extra labor is to be performed, or when new stimulus is considered necessary for extra-aphrodisiac effects. It is the universal testimony of all travellers that cuca begets a singular exhilaration, a feeling of buoyancy and light-heartedness, an increase of muscular strength, insensibility to fatigue, obtunding of the sense of hunger, a peculiar suppleness of motion, "long-windedness" at high altitudes, and decided stimulation of the genital sense. Garcilasso never observed any ill-effects from its use, and Van Tschudi remarks upon the good health and longevity of those accustomed to it. Markham says of it that it is the "least injurious, and most soothing and invigorating of all the narcotics used by man." Dr. Archibald Smith makes the statement that cuca, "when fresh and good, and used moderately," increases nervous energy, removes drowsiness, enlivens the spirits, and enables the Indian to bear cold, wet, great bodily exertion, and even want of food to a surprising degree, with apparent ease and impunity." And, though it has been accused of producing in excess tremor of the limbs and a gloomy melancholy, he has never seen a case of the kind in an acquaintance with its effects on all classes of people for many years. The article on this subject in the *British Encyclopædia*, which contains several of the remarks cited, quotes also from an apostrophe by the poet Cowley concerning coca:

> "Whose juice suc'd in, and to the Stomach tak'n
> Long Hunger and long Labor can sustain;
> From which our faint and weary bodies find
> More Succour, more they cheer the drooping Mind
> Than can your Bacchus and your Ceres join'd."

The physiological effects of coca were first scientifically studied by Mantegezza in 1858, who showed that when chewed it keeps the teeth white, facilitates the process of digestion, and diffuses a sense of warmth over the whole body. The mouth, nose, and eyes become dry after its use and there is a decided increase of strength, of motility, and heightening of the intellectual faculties. The drug was used as a remedy for various forms of "dyspepsia" attended with pain, colic, enteralgia etc. In the following year, 1859, the first chemical analysis of the drug was made by Niemann, who discovered the alkaloid cocaine, a principle which had the property, upon its application to it, of making the tongue almost insensitive. It is singular that although this observation was subsequently made by Carus, of Leipsic, who noticed also that the same loss of sensation occurred in the throat, both statements having been later repeated also by Fronmüller and Schroff, and that Aurep in 1880 noticed loss of taste as well as touch in the tongue, and loss of sensation in the skin after a hypodermatic injection of cocaine, it is singular that our knowledge of the range of the anæsthetic properties of cocaine should have been reserved to last year, when ensued the almost accidental discovery by Koller of the anæsthesia of the eye following the application of the muriate of cocaine prepared by Merck.

It does not pertain to our subject to speak of the local anæsthetic properties of cocaine which formed the subject of full discussion in this Academy a few weeks ago. Nor is there much to add regarding this active principle of the drug to what has been said already concerning the substance itself. Freud has just published (May, 1885) the results of his studies with cocaine, testing its effects upon muscle with the dynamometer and its psychic reaction with Exner's neuramöbimeter, confirming the observations of clinical experience. The failures, or want of effect, so often noticed with coca itself, find ready explanations in the statement of Merck that the quantity of cocaine contained in various samples of coca leaves varies between 0.2 and 0.02 per cent. So uncertain have been the results of the use of coca in its various preparations that it has been practically abandoned in the treatment of morphinism except as one of the agents *ut aliquid faciat*, among which numerous preparations the conscientious practitioner would select one which had received some sanction in the treatment of the special disease. Moreover, the various unknown changes which the alkaloids undergo in the stomach, together with the more sluggish absorption, and the cost of the drug, give good reasons of support for the clinical experience that the only certain speedy and effective mode of administration is by the hypodermatic method. It is best at first to combine the cocaine with morphia, the muriate of each alkaloid preferably, commencing with a grain of cocaine and whatever strength of morphia may be considered best in the individual case, having especial reference to the quantity of morphia used, and then gradually withdraw the morphia. An approximate idea of the quantity of morphia that has been in daily use may be learned, if concealed, from the effects of the cocaine, as the more exhilaration or euphora produced, the less has been the quantity of morphia.

It is necessary to continue with the cocaine for several weeks after the morphia has been withdrawn, for Burkhardt has shown that the so-called abstinence symptoms, excitement, unrest, neuralgias, chills, sweatings, insomnia etc., with unappeasable cravings for the drug, may set in after two months of abstinence. Opium is known to remain a long time in the body in intimate union with the protoplasm of nervous tissue. Stas claims to have found morphia in bodies after 13 months of inhumation, and Drag-

Digitized by Google

endorff and Kauzmann have shown that, mixed with moist organic matter, morphia preserves itself unchanged for months. It is essential here not to confound color reactions with the ptomaines, and to use in case of doubt the test of physiology. Such a mistake was actually made by Sonsegnos, and was rectified by Selmi after the manner mentioned, but this subject does not properly belong to this discussion. The fear of a cocaine habit is quite ungrounded, in fact. That is, there is no fear of danger, or of damage from small doses, and large ones produce effects too immediately unpleasant to lead to any abuse. The statement that the patient will return to his old habits in time is no real objection, as the physician is concerned only with the case in hand at the time and need have no more regard for the future than any other humanitarian, or at least no more concern than in the case of any other disease liable to return, malarial fever, for instance, with a new reception of the poison. During the interval of freedom the will of the patient may be, with proper methods, drilled to better discipline, just as, in time, we may sometimes drill with electricity the few twitchings of a paralyzed muscle to a more perfect tone.

CASE OF VARICELLA SIMULATING PEMPHIGUS.

BY W. H. GEDDINGS, M.D.,
OF AIKEN, S. C.

M. T., a little girl, five years of age, previously healthy, was attacked with scarlatina on the 26th of January. On the 31st the eruption disappeared, and the usual desquamation began. The latter process was exceedingly slow, lasting until February 14th. On the following day a number of translucent vesicles, about the size of a small split pea, appeared on the face and other parts of the body. A few of them were slightly umbilicated, but, as a rule, they were dome-shaped, quite thin, and filled with clear, serous fluid—presenting, in fact, all the appearances of varicella. The diagnosis was subsequently confirmed by the occurrence of several other cases of chickenpox in the same house.

Feb. 15 (second day of the eruption).—The vesicles are much larger, several of them being fully as large as a hazelnut. The contents of the vesicles have lost the crystalline appearance of yesterday, and become straw-colored. Any one seeing the case at this stage for the first time, and unfamiliar with its previous history, would at once have pronounced it to be pemphigus. She complains of some pain and considerable pruritus.

16th.—Pulse 126, but is reported to have been as high as 130. The bullæ continue to increase in size, some of those on the ankle being fully one inch in diameter.

17th.—Bullæ still larger, many of them being the size of an English walnut. On the ankle and leg several of them have become confluent, forming an immense bleb some four inches in length, occupying nearly the whole of the anterior surface of the leg, and almost encircling it. On the face and elsewhere there are a few fresh vesicles with clear contents, and differing in no aspect from those of an ordinary case of varicella. She suffers terribly with pain, and, where the cutis is exposed, the burning is so intolerable that she shrieks with agony.

18th.—No new bullæ.

19th.—Bullæ drying up.

20th.—Shrinkage of the bullæ and drying continue, but there is still some fever, and the little patient is so weak and exhausted with suffering that her hands shake like those of an old woman.

25th.—The bullæ and vesicles have all dried and exfoliated. She gradually recovered flesh and strength, and soon became bright and cheerful. At the time of her departure for her home, in New York, several months later, she had quite recovered her usual health.

We find, in dermatological literature, descriptions of varicella bullosa, and of urticaria bullosa, but, to my knowledge, no mention has ever been made of cases of varicella in which the bullæ exceeded an inch and a half in diameter.

TWO CASES OF DIPHTHERITIC CONJUNCTIVITIS.

BY G. DE SCHWEINITZ, M.D.,
OPHTHALMIC SURGEON TO THE CHILDREN'S HOSPITAL; PROSECTOR OF ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA.

THE opportunity of studying types of conjunctival inflammation, complicated by a deposit of diphtheritic membrane, is perhaps sufficiently rare to make the following cases worthy of record:

CASE I.—Nellie C., two and a half years of age, was admitted to the Children's Hospital, February 2d, of this year, at that time suffering from a severe attack of phlyctenular keratitis. The course of this disease was unusually stubborn, and many relapses occurred. When the child was finally on the fair road to recovery she contracted measles, which were then epidemic in the Hospital. Her case of measles, although uncomplicated, was very decided, the temperature on one occasion reaching 106° F. During the fever and also during convalescence a marked relapse of the eye troubles occurred; so that, by the time convalescence was fully established, the child was the subject of a most pronounced case of mucopurulent conjunctival catarrh, with ulceration of both corneæ, the surfaces of the upper lids of both eyes and a large area of the surrounding skin of the face being covered with eczematous ulceration. Under treatment these lesions gradually abated until May 23d, about two weeks after the attack of measles, when the eyes in all particulars again put on an angry look.

On the following morning the symptoms were more aggravated, and the conjunctival surfaces of both upper lids were more or less covered with a gray exudation. The same exudate was further present in the mucous membrane of the nostrils, a few patches on the inner surface of the lower lip, and quite generally on the eczematous ulcers of the face, especially on the lower lids, where they were in contact with the under surfaces of the swollen and overhanging upper lids and consequently in contact with the exudation. Further, the upper lids were hot,

Digitized by Google

tender and rigid, being difficult of eversion. The exudate, which was in, rather than upon, the mucous membranes, could not be wiped off, but was only detached with effort and left beneath a depressed and raw surface. In addition to these local manifestations marked constitutional disturbances were present. The pulse was rapid and feeble, the respiration noisy and frequent, the temperature elevated (101° in the morning, 103° in the evening), the tongue brown-coated and the skin harsh and dry.

In two days the membrane slowly changed from a gray to a yellowish-gray color; was more generally present and became more decidedly incorporated with the tissues. The suppuration, which had been so profuse, almost ceased; or, to speak more accurately, gave place to a thin, sanious discharge, intensely irritating, which ran from the eyes and nostrils and excoriated all surfaces with which it came in contact, adding thus to the general discomfort of the child and the disfigurement of her face. The exudation confined itself to the tarsal conjunctiva, leaving the ocular conjunctiva free, although greatly swollen and inflamed.

By the eighth day the disease, or at least its local manifestation, had reached its height, and from that time until the fourteenth day it gradually declined, the swelling of the lids slowly diminished, and the exudation both upon the face and conjunctiva disappeared.

At the present writing, one month after the onset of the disease, its external lesions have passed away. Both corneæ, however, have suffered severely. In each, the spot of previous ulceration has developed into an area of purulent infiltration with staphylomatous bulging, most marked on the left side, but in each also clear cornea remains, and later operative measures may restore fair vision to the child.

In the treatment of this case recourse was had to the following measures:

During the period of the greatest intensity of the local condition warm compresses were constantly applied to each eye. All affected areas were kept as clean as possible by frequently washing with a solution of bichloride of mercury (1:1000), and a solution of atropine (gr. iv–f℥j) was dropped into the eyes every three hours.

The constitutional treatment consisted in the administration of milk punch, quinine, and iron.

After the second day the child was given five minims of the tincture of the chloride of iron, and $\frac{1}{48}$ of a grain of bichloride of mercury every three hours and the quinine by suppositories. Variations in the treatment from day to day were necessary, but it is needless to refer to them in detail.

CASE II.—Joe W., aged ten, was admitted to my wards about the first of May on account of keratoiritis of his right eye. He was progressing favorably, when in his left cornea appeared a phlyctenule and later a phlyctenular ulcer, together with some conjunctival catarrh. This was pursuing the usual course of such a condition until May 27th, or four days after the disease in Case I. had appeared, when the eye and surrounding tissues took on great swelling, and an exacerbation of all previous symptoms occurred, especially of the catarrh, which became muco-purulent, or indeed entirely purulent. On the following day the upper lid was still more swollen, the discharge had diminished and a membrane, in all particulars resembling that seen in the case just described, appeared in the tarsal conjunctiva. On the third day the œdema of the upper lid was enormous; the purulent secretion had ceased; the cornea, a view of which could only be obtained with the greatest difficulty, was dull and hazy, "like that of a dead fish," and the membrane almost entirely covered the inner surface of the lids. Under treatment the symptoms gradually subsided, and now no traces of the disease remain, except a faint nebula at the inner margin of the cornea. The right eye, which was scrupulously protected, escaped infection.

In the treatment of this case, during the first thirty-six hours of the disease, iced compresses were applied to the eye and blood was taken from the temple, as the nutrition of the patient was good. These measures produced no appreciable effect, and at the end of that time for the cold compresses were substituted wads made of cotton steeped in water as hot as could be borne by the skin, the application being made for five minutes at a time every two hours. The cutaneous surface of this lid was further painted freely with collodion, with the hope that the contracting film thus produced would, by an even pressure, aid in diminishing the œdema. Strict attention to cleanliness, by the aid of antiseptic washes, was ordered, and mydriasis, by the use of atropine solution, maintained. In addition to these measures supporting food, milk punch, and quinia and iron were administered. The result of this treatment was most happy; the swelling subsided; the membrane disappeared; suppuration was reëstablished, and now scarcely any result of the disease remains.

Remarks.—It seems reasonable to place the epidemic of measles in direct etiological relation with the development of the first of these two cases. A child of depraved nutrition, disposed to facial eczema, and just convalescent from an attack of acute illness, is the typical subject for diphtheritic inflammation of the conjunctiva. It is further interesting that, in two other instances, this epidemic of measles in the Hospital was followed by diphtheria of other mucous surfaces—the larynx in one case and the fauces in another. In brief, the diphtheritic influence being present, this type of inflammation was the more readily engrafted upon a mucous membrane whose resisting power was lowered by previous inflammation and the effects of acute illness. To a certain extent the same conditions obtain in the second case; but it seems more natural to assume that, inasmuch as the same nurse attended to both cases, although in separate rooms, an accidental, but still a direct inoculation from the original case was the etiological factor. The fact that this attack pursued a much more benign course and recovery was reached without loss of any corneal tissue, is probably explained by the superior nutrition of this child as compared with that of the other.

Many other points in the etiology of diphtheritic conjunctivitis might be dwelt upon, but the whole subject has been so thoroughly investigated that it is only necessary to refer to the classical paper of A.

von Gräefe (*Arch. f. Oph.*, I., i. 168, 1854), and the more recent discussion by Mr. Nettleship (*St. Thomas's Hospital Reports*, vol. x., 1880). Gräefe, De Wecker, and other continental ophthalmic surgeons, have made a distinction, more or less sharply marked, between diphtheritic and membranous ophthalmia; while Nettleship, and more recently Juler, are disinclined to maintain this distinction. Be this as it may, it seems proper to classify the two cases just reported, by virtue of the course they pursued and the pathological lesions which they exhibited, as instances of true diphtheritic conjunctivitis.

I have to thank my colleague, Dr. B. Alexander Randall, for his assistance in the treatment of these cases; and also Dr. S. D. Risley for valuable advice, he having kindly seen the cases with me during a brief absence of Dr. Randall from town.

1330 SPRUCE STREET, PHILADELPHIA.

MEDICAL PROGRESS.

DIABETIC GLYCOSURIA IN OLD MEN.—DR. LANDRIEUX and H. ISCOVESCO reach the following conclusions relative to diabetic glycosuria in old men.

1. There is no reason to establish any essential difference between the terms glycosuria and glycosuric diabetes.

2. Senility gives to glycosuric diabetes special characteristics.

3. Senile glycosuric diabetes is ordinarily presented under the form of intermittent or remittent attacks.

4. Senile diabetes is frequently accompanied by other disorders of assimilation, as shown by azoturia, albuminuria, and the presence of the bile pigments.

5. The various mal-conditions observed in old men may be explained by a general ataxia of nutrition.—*La Progrès Médicale*, June 27, 1885.

FERRÁN'S CHOLERA INOCULATIONS.—Whatever may have been the attitude, whether of hope, of incredulity, or of suspension of judgment, which scientific men at first assumed with regard to Dr. Ferrán's alleged discoveries of the complete life cycle of Koch's bacillus, and of the immunity conferred by inoculation with it, he has, by his conduct towards the French Commissioners, headed by no less eminent a physician and sanitarian than Dr. Brouardel, completely put himself out of court, and thrown away all claim to the sympathy and support of the profession.

The disease that Ferrán induces in his subjects appears to be identical with, though happily for them milder than, that which Thiersch in his well-known experiments produced in mice, and which is now very properly held to have been a form of septicæmia, and not cholera at all; but that was in the dark ages of microzoic pathology.

But even supposing it were possible, as it may yet be found, to induce cholera by the injection of bacilli or their products, there is no ground whatever for imagining that it would confer immunity. It is true that those specific diseases, smallpox, measles, etc., one attack of which, as a rule, protects against a subsequent infection, and in which, therefore, artificial infection holds out a greater or less probability of a like immunity, do occasionally recur; but we have, considering the high mortality, the irregular distribution and the long intervals elapsing between epidemics of cholera in Europe, a number of instances of persons being again attacked, quite sufficient to justify the belief that one attack does not in any way protect against the disease in future, and that *à fortiori*, its inoculation, if practicable, would be utterly inoperative. Without repeating Jenner's experimental inoculations of smallpox after vaccination, persons are continually of necessity and in the path of duty exposed to risks and circumstances under which they must certainly have, in many cases, contracted the disease had not vaccination conferred protection. But in the case of a disease not contagious in the ordinary sense, as enteric fever or cholera, such conditions do not occur, and direct crucial experiment, as drinking the stools, being obviously inadmissible, it is difficult, if not impossible, to say that even some out of numbers of persons operated on must otherwise have been attacked. Protection, even as Ferrán asserts, for a few weeks is a pure assumption; indeed, the idea of temporary immunity requiring a repetition of the operation is entirely without analogy, and seems a mere device to obtain repeated fees.—*Medical Times and Gazette*, July 18, 1885.

THE CONTEMPORANEOUS USE OF IODIDE OF POTASSIUM AND CALOMEL.—A writer in *Il Morgagni* calls attention to the ill-effects following the local application of calomel to an ulcerated cornea in a patient who, at the same time, was receiving the iodide of potassium internally. According to the results of experiment upon animals, the reasons for the bad effect observed are that after some days the iodide of potassium is present in the lachrymal secretion, where, uniting with the calomel in the conjunctival sac, the protiodide and biniodide of mercury are formed; the first being irritant, the second exceedingly irritant, and even caustic. It is noteworthy that the same results have been noticed after baths of iodized water.—*Gazzetta degli Ospitali*, July 15, 1885.

NEW EXPERIMENTAL AND CLINICAL RESEARCHES UPON BRIGHT'S DISEASE.—PROF. MARIANO SEMMOLA deduces the following conclusions from the results of his latest experimental and clinical researches upon Bright's disease:

1. Albumen can traverse the renal tissue without any previous alteration in the histological elements of the kidney, and without leaving any trace of its passage.

2. If the passage of albumen is persistent, the first effect is hyperæmia with intraglomerular and intratubular hemorrhage, and the capsule is distended in a mass after boiling, and sometimes is simply raised and separated from the glomerulus by an empty space. There is also observed considerable migration of leucocytes without any alteration of the epithelium. The urine contains hyaline cylinders. These are the first results of an inflammatory action in relation with the functional activity of the kidney.

3. If the functional process persists beyond even eight or ten days, especially with the injection of albumen in the proportion of one gramme for every thousand grammes of the animal's weight, the invading process is attended by a mild inflammatory action, in

Digitized by Google

addition to a turbid swelling of the epithelium of the tubules, fatty degeneration, and thickening of the intra-tubular connective tissue.

This proves that the functional activity, which the kidney must sustain in the gradual and prolonged elimination of inassimilable albumen, is apt to provoke successively in different parts of the organ an inflammatory process which, commencing in simple hyperæmia, may result finally in the establishment of interstitial nephritis. Prof. Semmola is convinced by repeating the experiments and injecting very minute quantities of albumen, in order to have the experiments well under control and preserve the life of the dog for seven or eight months, that they will result in producing the last phases of the large white kidney—that is to say, the atrophic kidney.

4. The histological alterations in the kidney persist for some time after the injection of the albumen without producing a continuation of albuminuria.

5. Along with the elimination of albumen with the urine is also observed *albuminocholia;* that is to say, the elimination of a certain quantity of albumen with the bile.

In relation with the above experiments, Prof. Semmola proposes to continue his researches on the pathology of Bright's disease with the following experiments to determine:

1. The comparative influence upon renal elimination produced by the injection of albuminose, which is presumably more assimilable, such as serum of blood, albumino-peptones, white of egg, and milk.

2. The influence of albuminous injections upon the crasis of the blood, and upon the elimination of a quantity of albumen greater than that injected.

3. The influence of albuminose injections upon degree of activity in the combustion of nitrogenous matters and upon the production of urea.

4. The influence of albuminose injections upon the dyscrasic condition of the blood, and their relations with the production of anasarca.—*La Medicina Contemporanea*, June, 1885.

POWDER FOR PYROSIS.—M. PETER in *L'Union Médicale*, July 18, 1885, recommends the following powder in the treatment of pyrosis:

℞.—Sodæ bicarb. . . . . gr. xl.
Cretæ præcip. . . . . gr. xv.
Ext. nucis vom. . . . . gr. iss.
M. Div. in chart. No. x.

S. One three times a day for patients submitted to milk diet with whom the milk does not agree.

If diarrhœa is also produced, the subnitrate of bismuth should be prescribed in doses of ten grains combined with a sixth of a grain of extract of nux vomica, and from one-sixth to one-third of a grain of powdered opium.

LUMBAR NEPHRECTOMY.—MR. CLEMENT LUCAS removed (in Guy's Hospital, on the 14th instant) a distended floating kidney, filled with large calculi, which could be felt through the abdominal parietes. The operation was performed without difficulty through the loin, leaving the peritoneum uninjured. The patient is progressing uninterruptedly towards recovery, her temperature continuing normal as before the operation.—*British Med. Journal*, July 25, 1885.

A CASE OF CORYZA CASEOSA.—DR. BOURNONVILLE reports a case of coryza caseosa, in an old man, 72 years of age, a coal-burner by trade. The patient, since 1882, had been inconvenienced by stoppage of the right nasal fossa, lachrymation of the right eye and violent pain in the right forehead and side of the nose, angle of the eye, upper jaw, and teeth. After a long remission of the symptoms, the pain again returned and invaded also the left side of the forehead.

The patient finally sought admission into the hospital, chiefly for trouble experienced with his eye. Pressure upon the right lachrymal sac caused the escape of a mucous discharge, for which the canaliculi were slit and Bowman's sound daily introduced through the nasal duct. The sound was movable in all directions, and if allowed to remain for a short time was found coated with a dark-brown deposit, nearly half an inch broad.

By this treatment, the lachrymation was diminished, and the patient left the hospital. He, however, returned in a short time, and an inflammatory fluctuating tumor had made its appearance over the lachrymal sac, the contents of which could not be pressed through the canaliculi. Incision gave free exit to considerable quantity of pus. In a few days a fluctuating tumor made its appearance over the left inner orbital angle, by pressure upon which pus was caused to flow from the incision on the right side, but not from the canaliculi of the left side. Incision now was made into this tumor, and shortly two fistulous openings made their appearance at the root of the nose, giving exit to a scanty, thick, ill-smelling discharge. A sound introduced could be moved upwards, inwards, and downwards. When water was injected through one fistulous opening, it escaped partly through the other and partly through the canaliculi of the right side and the nostrils, or through the pharynx into the mouth. The water in passing through the fistulous cavities became turbid, fetid, and contained a quantity of caseous particles. Daily cleansing of the fistulous passages with a 2½ per cent. solution of boric acid, and injection of the nose with a weak solution of common salt, produced no improvement. Examination, in which a little finger was introduced into the right nostril, caused the patient to choke, and to discharge through the mouth several fetid, putty-like masses the size of a walnut. Examination showed that the antrum of Highmore communicated with the nasal passage by a passage easily admitting the finger, and contained similar masses to those already discharged, and easily recognizable by the finger. Little bleeding resulted from examination. By use of the nasal douche, two additional masses were evacuated and free passage of air through the nostrils established, and examination showed the antrum to be free. The left nostril was normal. The fistula on the right side of the root of the nose healed promptly, but that on the left persisted, while the water injected escaped, carrying with it cheesy matter as above. The fistula was accordingly dilated, the periosteum loosened, and the opening in the lower wall of the sinus enlarged, so that thorough cleansing by injection was possible. Examination again made by reflected light through the fistulous

Digitized by Google

opening, showed that only an inferior crest on the posterior wall of the septum remained,

The discharge of some additional putty-like masses and small pieces of necrotic bone followed the last-named treatment, after which the mucous membrane became clean and natural in appearance, and the wound healed in one week.—*Centralbl. für Chirurgie*, No. 16.

HYDRATE OF CHLORAL AS A PREVENTATIVE OF THE NIGHT SWEATS OF PHTHISIS.—NICOLAI, in the *Rif. Med.*, recommends hydrate of chloral in the night sweats of phthisis.

Two drachms of chloral hydrate are dissolved in two goblets of water and brandy in equal parts. In the evening, before going to sleep, the patient is sponged with the mixture.

If such application is insufficient, a shirt, wet in the same solution, is put on the patient during the night, and when removed the patient is wiped dry.

The effect of the remedy is excellent, especially in children suffering with the night sweats of phthisis. Frequently three or four applications are sufficient to cause cessation of the sweats, which persist for several weeks.—*Gazzetta degli Ospitali*, July 15, 1885.

TUMORS IN ANIMALS.—MR. J. R. BLAND SUTTON, F.R.C.S., in an elaborate study of tumors in animals, reaches the following interesting conclusions:

1. No tumors are peculiar to man; certain forms occur with greater frequency in him than in other animals, notably the cancers. This may depend on paucity of observations, but the conclusion is warranted by our present knowledge.

2. Sarcomata, fibromata, osteomata, and enchondromata are the most widely diffused of all growths; they occur in fish and all intermediate forms up to man. We have reliable evidence of the occurrence of osteomata in extinct forms; these growths constitute an ancient inheritance.

3. Fatty tumors are almost entirely confined to animals long domesticated,—the ox, horse, sheep, etc.

4. Odontomata are of frequent occurrence in mammals.—*The Journal of Anatomy and Physiology*, July, 1885 (London).

HYSTERICAL SUPPRESSION OF URINE.—A peculiar case has been communicated by DR. T. J. GRIBLING, of Waalwijk, to the Netherlands Medical Society, where there was profuse perspiration, accompanied with partial, and, for a time, complete suppression of urine. The patient was a girl of nervous constitution, who was, however, in good health till she was about 12, when she somewhat suddenly complained of extreme fatigue and want of power in the legs. She then began to suffer from violent headache of the left frontal region, which, though persistent, always became especially violent at noon. In the evening, when it abated, profuse general perspiration came on. When the writer first saw the child, this had been going on for some months. There were converging strabismus, and quick respiration and pulse; the temperature was normal, and no organic disease could be detected. The legs were quite powerless, but gave normal electric and reflex reactions. She had not at that time menstruated. The bowels acted very rarely, and the quantity of urine was very scanty. The food taken was very small in quantity; nevertheless, the girl's weight did not materially decrease. This state of things continued for a year, uninfluenced by arsenic, atropine, and numbers of other remedies which were tried. The suppression of urine then became absolute, and the perspiration still more profuse. The author was careful to remark in the patient's hearing that, when the urine returned, the perspiration would be diminished. In about five weeks' time, menstruation occurred, and a quantity of urine was passed. On this, the girl said to her mother: "Now the sweating will cease;" and, in fact, it did so, and did not return. The urine continues to be passed in satisfactory quantity, but there are still headache and want of power in the legs.—*British Med. Journal*, July 25, 1885.

A NEW METHOD OF ADMINISTERING PEPSIN.—DR. PROSSER JAMES recommends the following method of administering pepsin. He says:

In adding another to the numerous preparations of pepsin, it is unnecessary to enter upon its physiological or therapeutical action. Pepsin has conquered for itself an important position in modern practice, and the new preparation is simply designed to render its administration more easy, as well as more satisfactory. The importance of administering it within a short time of taking the food on which it is expected to act has been generally appreciated, so far as giving directions for the dose to be taken a little before or a little after a meal; but too often these directions are not implicitly followed, partly, perhaps, from the prejudice many patients have to take physic with their food; moreover, this plan is ineffectual. In natural digestion the pepsin is not all poured on the food at once. By the movements of the stomach its contents are successively exposed to the action of the gastric juice as they come in contact with the walls. To imitate this we might take pepsin in successive portions; but patients, who mostly think it hard to swallow a single dose of medicine with a meal, will not be easily persuaded to sip it, and they usually object to the taste of the liquids. There are other reasons why some of the preparations in common use are ineffectual. Thus, when taken with strong wines, the pepsin is precipitated, and the vinum is perhaps the worst preparation we can employ.

To secure pepsin being taken at the time it is required—that is, with the food on which it is to act—I have endeavored to convert it into a condiment. At first I tried a sauce, but with less success than I had hoped. Considering that pepsin is so associated in digestion with hydrochloric acid that some have held that a definite compound—pepto-hydrochloric acid—is formed, it occurred to me that, as chloride of sodium is the universal condiment, a combination with that salt offered the most likely solution of the problem I had set myself.

A simple mixture of pepsin with salt may be successfully employed as a digestive condiment, provided it be freshly prepared each time; for such a mixture, if kept, is apt to decompose, and the patient who has once observed this will take no more of the putrefying powder. How to overcome this difficulty was the next problem; and this has been also solved. The pepsin and the chloride must be brought together in such a way that possibly a compound, or pepto-chloride, may be formed.

Digitized by Google

Whether such union occur or not, a powder thus prepared is quite stable. I have before me now a sample made many months ago, which has been used at intervals at the table in place of common salt. It has a faint color, which is not objectionable, and used as table salt is nearly indistinguishable from that condiment. Here, then, is a digestive condiment, a peptic salt, which many may be glad to try, and which has already given me satisfaction.

I propose to call it "peptic salt," or "digestive salt," or it may be ordered in prescriptions, if preferred, as salt-pepticus, or as pepto-chloride of sodium. Ten grains of my peptic salt will dissolve nearly 200 grains of hard-boiled albumen, or two ounces of lean-cooked meat. It may take the place of table-salt in the dyspeptic's dietary.—*The British Medical Journal*, May 16, 1885.

TREATMENT OF VOMITING IN THE INTESTINAL CATARRH OF CHILDREN.—DR. J. M. KEATING recommends the following as a very valuable remedy in the treatment of vomiting in the intestinal catarrh of children:

℞.—Sodæ bicarb. . . . . gr. xv.
Creasotæ . . . . . ♏ij.
Syrupi acaciæ . . . . fʒss.
Aquæ lavandulæ . . . fʒj.—M.
S.—Teaspoonful.

As the most valuable prescription for the treatment of cholera infantum, he recommends the following:

℞.—Morphiæ sulph. . . . gr. ½.
Acid. sulph. aromat. . . gtt. xxxij.
Sp. vini gallici . . . . fʒij.
Syrupi simp. . . . . fʒss.
Aquæ anisi . . . q. s. ad fʒij.—M.
S.—Teaspoonful every hour.—*The Archives of Pediatrics*, July 15, 1885.

CORROSIVE SUBLIMATE AS AN ANTISEPTIC IN OPHTHALMIC SURGERY.—M. CHIBRET read a paper before the third session of the French Society of Ophthalmology, in which he pointed out that notwithstanding the benefits that may frequently be obtained from the use of boric acid and carbolic acid, when an antiseptic is required, they frequently disappoint expectation. M. Chibret has for the last eight months employed corrosive sublimate with great advantage. At first he used it in the form of lotions and ointments, but lately he has had recourse to irrigation, the strength of the solution being 1 in 2000, a strength that is well borne by the healthy eye. It may be applied six times daily. In the first instance, M. Chibret employed it in cases of keratitis with severe and extensive inflammation and hypopyon. Struck with the extraordinary diminution in the degree of suppuration, he ventured to employ it in a case of panophthalmia from punctured wounds, and was not afraid to allow the fluid to penetrate into the interior of the eye. He was delighted to find the ophthalmia promptly arrested. In other cases of keratitis the same success attended the use of the remedy. He dwells on the importance of making the jet of fluid impinge with a certain amount of force on the tissue of the cornea and sclerotic, so as to have a certain penetrating power, and so to act not only on the surface but upon the deeper layers of these membranes. When the eyes are very irritable and the jet cannot be well borne, cocaine may be employed.—*The Practitioner*, July, 1885.

LOTION IN EXCESSIVE PERSPIRATION.—PROF. KAPOSI recommends the following lotion in excessive perspiration:

℞.—Naphthol . . . . . gr. lxxv.
Glycerinæ . . . . . fʒijss.
Alcoholis . . . . . fʒiijss.—M.

S.—Dissolve. Bathe the region which is the seat of hyperidrosis once or twice daily with the solution, and powder with simple starch or with starch and naphthol—2 parts to 100. In the case of profuse perspiration of the feet, put small pieces of wadding sprinkled with this powder between the toes. If baths with the lotion cause erythema, they must be suspended. In phthisical patients, when night sweats are severe, the use of the alcoholic solution of naphthol—1 or 2 parts to 100—frequently produces amelioration of the symptoms.—*L'Union Médicale*, June 27, 1885.

ON THE IMPORTANCE OF EARLY PARACENTESIS IN THE TREATMENT OF ASCITES.—DR EDWARD DRUMMOND, in a paper upon the foregoing subject, says:

It was certainly the practice once, and I believe it is still largely the case, to defer this operation too long, and only resort to it as a mere palliative measure, in order to give a few hours or days of respite from the suffering to which the presence of so much fluid in the abdomen naturally gives rise.

I have witnessed a large number of cases of cardiac, renal, and hepatic dropsy, in which all the ordinary routine treatment by drugs, hot-air baths, etc., failed to arrest, by a single hour, the onward march of the disease and its accompaniments; where a laboring heart, a cirrhosed liver, or disorganized kidney, had its difficulties intensified by the mere hydrostatic pressure of a great mass of fluid distending the peritoneal cavity.

Not to mention the increased difficulty, nay, the almost impossibility, of necessary movement, exercise, etc., all absorbent action of the vessels must be reduced to a standstill, every function of digestion, assimilation, micturition, defecation, obstructed; respiration and oxygenation of the blood impeded; the heart's action embarrassed; and the mere weight of fluid rendering compulsory the maintenance of a sitting posture, by day and night, must be fearfully exhausting to a patient in so advanced a stage of disease, in which the blood is so impoverished and so highly charged with the products of arrested secretion.

Proper diet, with a minimum of fluid, and such medicines as acetate of potassium, sulphate of magnesium, nitrous ether, jalap, elaterium, and other hydragogue cathartics, and still more, perhaps, digitalis, casca, or convallaria majalis, are no doubt useful, especially in the early stages, while iodide of potassium with iron and Baillie's pill must not be forgotten. All these, however, and many more similar preparations, will only excite illusive hopes.

If the fluid be removed by *early*, and, if necessary, *repeated* "tapping," followed by well-regulated firm

Digitized by Google

pressure, then these remedial agents become really potent for good.

It is generally held that such a course of treatment is more especially useful in dropsy dependent upon cirrhosis, but I have found it less successful in cardiac and renal dropsy, and, in a fair proportion of cases, it has proved *curative*, while in all it has diminished the patient's sufferings, and made his invalid state endurable.

Where an advanced form of Bright's disease, a progressive cardiac lesion, malignant or albuminoid disease of the liver, or like inevitably fatal malady, stands behind, it can of course only be a palliative, but it is a *real* one; it robs a necessarily fatal illness of its worst horrors; gives literally *a breathing space*, a respite from unavoidable suffering, and adds some weeks or months of comfort to a doomed existence.

When, however, the ascites depends on a cause which is temporary—wholly removable or capable of becoming stationary—then paracentesis so practised is the chief means of cure. In any case it is impossible to insist too strongly on the importance of an early recourse to it, as adding tenfold efficacy to otherwise impotent therapeutic means.—*The Practitioner*, July, 1885.

DIAPHORETIC TREATMENT OF NEPHRITIS.—The *St. Petersburg Med. Woch.*, quoting from *Vrach*, reports the treatment of nephritic patients by N. HESS by wet packs, hot baths supplemented by wrapping in blankets, and hot-air baths, and draws the following conclusions: (1) The least rise of temperature occurs with packs, the greatest with hot baths. (2) While the temperature is found to sink still further twenty minutes after the pack, it remains at the same height for an hour after both the other methods of treatment. (3) After water baths the temperature regains its original height more slowly than after air baths. (4) During the pack the pulse becomes slower; during both water and air baths, on the contrary, it is quickened for an hour afterwards. (5) Under the influence of the pack, respiration is moderately quickened; during both water and air baths it is still more quickened, but subsequently returns to its normal rate more rapidly than after the pack. (6) The most powerful sudorific effects are produced by hot baths, the least powerful by packing. (7) Though the baths are more stimulating, packing soothes the action of the nervous system, brings the patient on better, and produces a subjective feeling of improvement afterwards.—*The Lancet*, June 27, 1885.

NERVOUS COLIC.—DR. SHERSHEVSKI, in the *Lyon Médical*, March 1, 1885, reports a number of cases of colic which seemed to be due to a neurasthenia of the nervous elements of the intestinal canal. They were all in intelligent individuals whose work was chiefly mental. These persons suffer habitually from constipation, with abdominal distention and burning eructations, but without loss of appetite. From time to time, under the influence of prolonged intellectual work or of mental emotions, an aggravation of this condition occurs, with the following symptoms: Excessive meteorism with or without a discharge of gas from the bowel, superficial panting respiration, cyanosis, pains in the neighborhood of the liver or in the umbilical region, or shifting, or feeling of weight in the lower part of the abdomen and severe tenesmus. The attacks subside after some days with the occurrence of copious evacuations. Shortly before their onset the feces become flattened, as if there were an intestinal stricture. The author attributes these symptoms to a lesion of the nervous system producing an intestinal spasm ocated in the circular fibres of the muscular coat. This theory of the etiology would seem to Dr. Shershevski to be demonstrated by the action of the remedies employed. For, while purgatives increase the pain and constipation, opium and belladonna reduce the meteorism and cure the attacks.—*The Practitioner*, July, 1885.

TREATMENT OF DIPHTHERIA BY THE HYDROCARBONS.—DR. DELTHIL, in the *Journal de Médecine de Paris*, gives the following practical exposition of the treatment of diphtheria by the hydrocarbons:

1. If a suspicious contact causes fear of angina maligna, as prophylactic measures, the individual may be submitted to vapors of the essence of turpentine, either by allowing him to respire them from time to time or by impregnating a couch, upon which he should recline, with the substance.

2. If diphtheritic symptoms are manifested, but do not appear especially grave, it will be sufficient to impregnate the patient's room with the vapors of turpentine, by submitting the remedy to a temperature of 140° F., by a warm-water bath.

The turpentine should be crude, and not rectified. Naturally, of course, the quantity evaporated should be proportionate to the size of the room. In a very large chamber numerous evaporating vessels are necessary. In nearly every case such vaporization is sufficient to prevent diphtheritic angina, if used at the initial period of the attack.

3. If after such measures the symptoms become more serious and assume a toxic character, fumigations, by combustion, of gas tar and spirits of turpentine should be practised as follows:

Take about ten drachms of tar and eight drachms of crude turpentine in a metal or earthen vessel. The mixture is then set on fire, and the fumigation thus produced should be repeated every two hours, or at greater intervals when amelioration is produced.

In order that the procedure may be successful, it should be carried out in a small room, in which all the outlets may easily be closed. Into such room the patient should be carried, and allowed to remain a half hour, and then be removed to his own chamber where the evaporation of turpentine should be constantly maintained. If the odor of turpentine, as sometimes happens, is too penetrating, this effect may be obviated by the addition of spirits of lemon or lavender, thus producing a true perfume.

Local applications of lime water or lemon juice should be made at least every hour, day and night. In the same manner a mixture of oil of sweet almonds, spirits of turpentine, lemon or lavender, with the yolk of an egg, and syrup of mucilage, may be used. Ipecac should be used as an emetic when it becomes necessary to rid the bronchi of free diphtheritic exudations. Tracheotomy, if necessary, should also be performed.

The duration of the treatment is commonly from twelve to fifteen days, during which the fumigations

Digitized by Google

may be practised without danger even in children only a few months old.

Sulphate of quinia should also be employed when systemic intoxication exists, and the temperature of the sick-room should be kept at an elevated point.

SUPRAPUBIC CYSTOTOMY.—MR. F. SWINFORD EDWARDS, at the conclusion of a clinical lecture upon the above operation, says: Suprapubic cystotomy is on the whole the best operation for establishing a permanent outlet for the urine in cases of enlarged prostate and contracted bladder, where, the patient having to void on all occasions his urine by means of an instrument, lives in constant dread of the never-ending instrumentation. Of the relative merits of the suprapubic and prostatic punctures in cases of distended bladder with enlarged prostate, it is difficult to judge until we have more cases of the latter submitted to us. Personally, I should be inclined to favor the prostatic puncture on account of the capital drain it provides, and I should not be surprised were it in the future to take the place of both the rectal and suprapubic punctures where the outlet for urine has to be permanent.—*London Medical Times*, May 30, 1885.

TREATMENT BY SECTION OF HYDROCELE BY THE ANTISEPTIC METHOD.—MR. EDWARD BELLAMY, in discussing the treatment by section of hydrocele by the antiseptic method, says: The few remarks I make are based upon the results of a considerable number of cases I have treated, both in hospital and in private practice, in the early and later stages of hydrocele, by which latter I mean those which have been repeatedly tapped and in most instances injected. It is hardly necessary to take up space by instancing the individual cases. It is certainly time that the old-fashioned method of tapping and the supposed radical cure by continuous injection was done away with, as painful, dilatory, and generally useless. I claim no originality whatever in this treatment. I desire to call the attention of practitioners to the fact that they should invariably adopt the method of free incision with strict antiseptic precautions, and I cannot understand why it is not more universally carried out. Every surgeon knows of the method, but, as far as I see, contents himself with adhering to the usual proceedings. There is no danger in it. An anæsthetic can be given if necessary, the healing is rapid, the cure almost certain, if not absolutely so. The operation is as follows: The diagnosis, of course, being established, the scrotum should be shaved, and (if the surgeon thinks necessary) the spray used, the tumor is firmly grasped so as to render the parts as tense as possible. A clean sweep through all the scrotal tissues is then made with the bistoury from the cord to the base, and the fluid escapes. Every bleeding vessel, however small, must be twisted or tied most scrupulously, and the interior of the sac carefully examined for any vessel which may have been wounded or have given way. The cavity should then, not too tensely, be stuffed with either lint soaked in 1 in 40 carbolized oil or gauze, and the upper part of the edges of the wound stitched together, including all tissues—I do not see any advantage in stitching the cut edges of the sac to the sides of the wound—a small tag of the contents being left out of the most dependent part on the contingency of drainage, a pad of salicylic wool placed over all, and the scrotum supported by a cushion between the thighs. In a couple of days the parts may be dressed (under spray, if thought desirable), and the contents of the sac withdrawn. As a rule, considerable contraction of the walls of the sac will have set in, but it is advisable still to introduce the antiseptic material so long as any appreciable cavity exists, and this is generally for about a week in very favorable cases, when it will be found impossible to pass anything into it, and merely the lips of the original wound are left to close. Tubal drainage is, I venture to think, unnecessary. I have not yet met with any untoward constitutional symptoms by adopting this method, which is equally applicable to encysted hydrocele of the cord.—*Lancet*, July 4, 1885.

A NEW CASE OF CURE OF ILEUS BY WASHING OUT THE STOMACH.—DR. KUHN, in the *Bulletin Général de Thérapeutique*, of July 15, 1885, reports a case of ileus cured by washing out the stomach.

The patient was a man, aged about 60 years, and for a year previous had been subject to colic with alternate attacks of constipation and diarrhœa. For some time, however, these intestinal disorders had disappeared almost completely, when suddenly, on May 8, 1885, the patient was again seized with colic more violent than he had ever before suffered, and this in a short time was followed by vomiting. Dr. Kuhn was summoned, and found the patient suffering the greatest agony. The last matters vomited had a fecal appearance. Meteorism was considerable, and the hand applied to the belly easily distinguished the tumultuous movements of the distended intestinal coils. Very little gas escaped from the rectum. There had been no stool since the day previous. Nausea was persistent, and the temperature was normal. Treatment was carried out as follows: An injection of warm water was made, and in an hour followed by a second, of about seven drachms of castor oil, neither of which was followed by any result. At intervals of an hour, two hypodermic injections of $\frac{1}{4}$th grain morphia were given, and for treatment during the night a potion containing one drachm of chloral was prescribed.

In spite of the use of these drugs, the patient was restless during the whole night. The meteorism still persisted, as did also the nausea. Washing out the stomach was then proposed, and performed with a solution of soda bicarb. in a proportion of 3 to 1000.

The liquid did not return limpid until about two gallons had been used. The same evening, four or five hours subsequent to the treatment by irrigation, gas began to escape from the rectum, with consequent diminution of the meteorism. Though the improvement of the patient was very manifest, no movement of the bowels occurred, and, after waiting twenty-four hours, a second irrigation was made with water and soda bicarb., 6 parts to 1000. An injection of f ℥iss castor oil was administered, and eight granules of strychniæ sulph., each containing $\frac{1}{60}$th grain, were given, one every two hours. The same evening, movement of the bowels occurred, the meteorism entirely disappeared, and the patient recovered.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, AUGUST 8, 1885.

CHOLURIA.

THE detection in the urine of biliary derivatives —except bile pigment, in the most general sense of the term—has always been imperfect and unsatisfactory. It is well known that Pettenkofer's test for the bile acids, by means of solution of cane sugar and sulphuric acid, so brilliant with the pure bile acids, or with inspissated bile diffused in water, is totally inoperative, even when bile is added to the urine. The determination of the clinical significance of such presence has, of course, been correspondingly unsatisfactory. Clinicians will, therefore, hail with pleasure any method which promises greater certainty than is now had in testing for these substances.

Such certainty seems to be promised by the recent researches of DR. GEORGE OLIVER, which appear in the third edition of his valuable little book, just published, on Bedside Urine-testing, and for which its present title is altogether too modest. In the first place, Dr. Oliver is disposed to consider that Pettenkofer's test does not react directly with the liver secreted salts, taurocholate and glycocholate of sodium, but only with the derived salt, the cholate. Hence, it does not indicate the presence of the biliary salts in fresh ox-bile until the latter have had time to decompose, and thus liberate the cholic acid; but it reacts at once and decisively after the bile has been boiled several hours with caustic potash, a procedure by which the bile-salts are broken up and the derivative, cholate, furnished. This, according to Dr. Oliver, is the reason why Pettenkofer's test acts with inspissated, and not with fresh bile, for the extract is an evaporated product, and the taurocholates are decomposed by simple boiling. This, too, explains why it fails to afford a distinctive reaction with jaundiced urines, which are highly charged with bile salts.

Dr. Oliver's proposed test is founded upon the physiological fact that when the products of gastric digestion, peptone and parapeptone, which leave the stomach in an acid solution, meet with the bile, they are thrown down in the shape of a tenacious layer over the entire mucous membrane of the duodenum. In like manner a solution of bile salts precipitates acidulated albuminous urine, or urine charged with peptone, and this precipitation of albuminous matter from an acid solution is also caused by the derivative of the bile salts, cholate of sodium, so that acidified albuminous urine becomes a test for bile salts, but an acidulated antiseptic solution of peptone is a readier and more delicate reagent. Such a solution Dr. Oliver makes by adding thirty grains of Savory & Moore's pulverized peptone, four grains of salicylic acid, and thirty minims of acetic acid to eight ounces of distilled water, and filtering to secure perfect transparency.

Now if twenty minims of perfectly clear urine, of normally acid reaction, reduced to a specific gravity of 1008 and containing bile salts in morbid quantity, are run upon sixty minims of the test-solution, a sharply defined, white band of peptone appears at the border between the two fluids; and on oscillating the tube, so as to mix a little of the urine with the test-solution, the upper part of the column presents an opacity, the density of which is proportionate to the amount of bile derivatives present, in marked contrast with the transparency of the urine below. On further agitation, the opalescence diminishes, and, perhaps, finally vanishes, but it is restored on adding more of the test-solution. The precipitate differs from all other urinary precipitates induced by an acidified reagent, in dissolving completely on adding a drop or two of acetic acid, or a citric acid test-paper, and diminishing, but not disappearing, on boiling, but the opacity is not affected by such a degree of warmth as is sufficient to dissolve urates. Further, an insufficiency, as well as an excess of acid interferes with the reaction, as also does an excess of proteids or of the bile salts themselves. Hence the importance of securing the proper proportions, as in Dr. Oliver's formula, and of diluting the urine to be operated upon.

This test, according to Dr. Oliver, is so delicate that there can be readily determined by it, one part of bile salts in at least 18,000 to 20,000 parts of a solution of chloride of sodium. So far he has been unable to find any other constituent of urine which will react similarly; and, although it is true that a concentrated solution of chloride of sodium in the presence of an acid will precipitate a proteid, experi-

Digitized by Google

ment shows that when the peptone solution is run upon a solution of salt of any specific gravity below 1050, no precipitation takes place. If the urine contains the average proportion of bile salts found in the majority of healthy urines, or less, the reaction is a mere tinge of milkiness, and is, also, not immediate.

In further proof that this reaction with urine points to bile salts as its source, we have the following facts: (1) That biliary salts extracted from the bile produce an identical reaction. (2) That all the secretions, except bile, either do not act on the proteids at all, as saliva, or they dissolve them, as the gastric and pancreatic juices; and that the bile salts are the only constituents of that secretion which possess the property of throwing a proteid out of solution. (3) The test demonstrates that the proportion of bile salts present in normal urines varies in a well-defined degree with the activity of the digestive organs, showing that the agent reacting with the test is intimately connected with the digestive process. (4) Clinical experience.

As to further sources of error, mucin may be eliminated, because this substance in acid solution is not precipitated by the addition of more acid, and when it is thrown down in urine of acid reaction, it is highly probable that the acid added is not the reagent producing it, but merely supplies the requisite degree of acidity to enable the precipitant already present to operate, and in that event the mucin would only indicate the presence of bile salts.

Urates cannot become a source of error since the mode of application of the test, both qualitative and quantitative, requires the urine to be diluted to a specific gravity of 1008, by which solution of the urates is secured. In addition to the reason above given, the reduction in specific gravity to 1008 is done to obviate such fallacious results as are liable to occur in operating with urines of different densities—concentrated urines often simulating an excess, while urines of low specific gravity, though affording reaction similar to normal urines, may actually contain more than the normal amount of bile salts.

As further conditions of success, the urine, if not perfectly clear, should be made so by filtration; if cloudy from blood, it should be first boiled and then filtered. If alkaline, it must be brought to a normal degree of acid reaction by acetic acid.

Dr. Oliver has also made a peptone test-paper for bile-salts, and applies the test quantitatively, but for the details of this process we refer our readers to the book.

MODERN PHYSIOLOGICAL CONCEPTS.

THOSE physicians who acquired their instruction in physiology twenty-five years ago, and who have not given special attention to recent advances in that science, are somewhat bewildered occasionally by the modern views of which they from time to time catch glimpses in the journals. The very language is unfamiliar—katastates and katabolism, inhibition and trypsinogen were not mentioned in their text-books or by their lecturers; there seems to be a new chemistry mingled with the matter, and electrical apparatus of more or less complex arrangement seems a necessity at almost every step of modern physiological laboratory work.

To all such, who would like to obtain a general idea of the nature of the change which has occurred without being compelled to make a study of details, the article on physiology in the recently issued volume (xix.) of the *Encyclopædia Britannica* may be commended.

In this article Professor Michael Foster remarks that while the study of chemistry and physics should precede that of physiology, yet the exigencies of life brought the study of man, and so of physiology, to the front before its time; and hence the history of physiology shows many premature and vain attempts to solve physical and chemical problems before the advent of adequate physical and chemical knowledge. One of the first concepts of a living animal was that it is a complex of organs, each having its respective function, and hence the terms "organism" and "organic" came into use as distinctive of living things. On this theory the principal object of physiology was to discover the functions of the different organs, and, as far as possible, to show the connection of these functions with the location and structure of the organ. The simplest possible organ was supposed to be the cell, but presently it was found that simple plasm, with no differentiation into wall and contents, was capable of presenting all the phenomena supposed to be peculiar to life, and hence a new concept arose, viz., that organization is a concomitant and a result of vital action, but not its condition or cause.

Protoplasm, in Huxley's phrase, became the physical basis of life. This protoplasm differs in the relative prominence of one or another of the attributes or powers which are common to all protoplasm—*i. e.*, assimilation, contractility, etc., and these differences are supposed to be connected with corresponding differences in molecular constitution.

A mass of living, active protoplasm is compared to a fountain, the shape of which remains the same, although its constituents are constantly changing.

If we examine a cell of the pancreas we find that during a period of rest succeeding one of activity the cell increases in size, owing to an accumulation of material in the meshes of the network of protoplasm forming the cell. This material thus stored up is not precisely the same substance as that which characterizes the fully formed secretion. The characteristic

Digitized by Google

constituent of pancreatic juice is a peculiar ferment called trypsin, and the granules which swell the pancreatic cells are not trypsin, but a material which, with a slight change, becomes trypsin, and which is called trypsinogen. This trypsinogen is more complex in composition than trypsin, and in its turn is supposed to be derived from a still more complex body—to be, in fact, a product of the metamorphosis of the protoplasm itself. This intermediate stage may be termed a mesostate, and as a mesostate may occur either in the process of building up or of decomposition, the term anastate is applied to the former, and katastate to the latter; trypsinogen, therefore, is a katastate.

So, also, in the action of a muscle cell there is supposed that a katastate called inogen is formed, and that this inogen is the source of the energy or force produced.

The building up of protoplasm stores up energy, which is set free in the breaking down. The same conception is applicable to nervous impulses, but we must refer to Professor Foster's paper for details. Those who are familiar with modern physiology will best appreciate his very clear exposition of some of the more recent theories, but the paper is not written especially for medical men, and will be enjoyed by any educated thoughtful reader.

When we began this article it was with the intention of commenting on the extent to which modern physiology is beginning to influence practical therapeutics, but want of space compels us to defer this until another time.

THE INTERNATIONAL MEDICAL CONGRESS.

RAPID disintegration still characterizes the new organization of the Congress. This week we are called upon to chronicle more resignations, and the list includes one Vice-President of the Congress, three Vice-Presidents of Sections, and several members of Councils. The very large number of appointees who have declined to accept office under the New Orleans committee are all Old Code men, both in principle and practice, and for the most part they are members of the American Medical Association. They recognize the falsity of the issues which were raised at New Orleans and they have promptly placed their emphatic seal of condemnation upon the most disgraceful piece of intrigue which has yet marred the history of that body, and which is in imminent danger of placing an ineffaceable stigma upon the good name of the whole American medical profession.

Although the hollowness of the Code cry has been fully exposed, we still find it being freely used by the new Committee and we learn that a circular, to which signatures are invited, has been extensively circulated through this State, expressing approval of the exclusion of the New Code men from membership in the Congress, and applauding the work of the Committee at Chicago, and it is headed "The action of the American Medical Association endorsed." The first response it appears to have elicited was the resolutions condemnatory of the action at New Orleans which were passed by the Allegheny County Medical Society and published last week, and this week we hear the echo from Texas.

The profession recognizes that on account of recent events there is imminent danger of its not being able to meet the obligations which it incurred by the invitation extended in its name at Copenhagen, and its members naturally look around to see what means can be found to avert the impending disaster which threatens to defile its good name.

The clearest and cleanest way out of the false position into which the profession has been entrapped by the plotters at New Orleans is for all appointees to discredit them completely by declining to accept office at their hands, and thus their organization must, of necessity, collapse. Already this has been largely done, and upwards of one hundred and twenty of the most eminent of their appointees have declined to be tools in their hands, and the sooner the remainder follow suit, the sooner will the way be opened to the profession to redeem its plighted honor.

At an early day THE MEDICAL NEWS will publish a complete list of the new organization of the Congress, showing who have declined to accept office under the new Committee. Gentlemen who have determined to refuse the positions to which they have been appointed, but whose resignations have not been published, are requested promptly to send notice of their intention to this office.

THE LAW REGULATING HOUSE DRAINAGE IN PHILADELPHIA.

THE law regulating house drainage in Philadelphia, which was passed by the Legislature of Pennsylvania at its recent session, will enable the Board of Health of that city to extend its usefulness to a branch of sanitary work over which it has heretofore had very limited control. Repeated efforts made within the past two years having failed to induce City Councils to adopt an ordinance having the same object in view as the law just passed, a conference was held between the Master Plumbers' Association of the city and the Board of Health, at which it was agreed to appeal to the Legislature, and accordingly a bill was prepared and forwarded to that body with a petition setting forth the necessity for the adoption of such a measure. The present law is the bill thus presented with slight amendment.

Digitized by Google

In a former number we pointed out the defects in house drainage and plumbing which have become exceedingly common in this city, mainly in consequence of the want of a proper law regulating such work. A radical change in the prevailing objectionable practices may now be expected. The responsibility of the administration of the law devolves on the Board of Health. This body is given the fullest authority to adopt and promulgate suitable rules and regulations for the construction of house drainage and cesspools, and to provide for the registration of master plumbers and persons engaged in the plumbing business. It is authorized to establish a system of inspection and supervision over all house drainage, etc.; and, any violation of the rules and regulations it may adopt, is made punishable by severe penalties, and even by imprisonment.

In adopting regulations governing the business the board has the advantage of the experience of other cities which have already established a system of house drainage, and will thus be enabled to avoid mistakes which are apt to be committed by the inexperienced in any undertaking. The authority conferred is almost unrestricted, and it remains for the board to use it wisely. The Master Plumbers' Association is in hearty sympathy with the new movement, and may be relied upon to assist in the work of organization. It is to be regretted that cesspools in present use are excepted from the provisions of the act. It is said that this provision saved the bill from defeat, as there is a strong opposition among the people to any measure which would permit of the extinction of cesspools, which exist in great numbers in Philadelphia. Permanent cesspools, as forming a structural portion of the dwelling, are almost invariably nuisances, and ought to be superseded whereever sewers are accessible. It is not necessary, nor is it practicable to sweep these structures out of existence at once; but the regulations might have been framed so as to cause them to be abandoned gradually, without imposing too severe a burden upon any one. However, as the law stands, it is an exceedingly valuable addition to the sanitary statutes of the city, and its vigorous and wise enforcement will undoubtedly be of immense advantage to the public health.

A SUBSTITUTE FOR EMMET'S OPERATION.

DR. CORTIGUERA discusses Emmet's operation, in a paper recently presented to the Obstetric and Gynecological Society of Paris, an abstract of which is published in the July number of the *Archives de Tocologie*. He states that Emmet and those who have repeated, or who have parodied, his doctrines, say that in labor a fissure, of greater or less extent, occurs in the lips of the uterus, and that this lesion causes different disorders which constitute morbid entities, more or less grave, and the only remedy is to revive the disjoined surfaces and unite them.

It is not necessary for us to say that this is not a fair statement of Emmet's views—but so far as the parodists are concerned, it may be true.

Cortiguera divides tears of the neck of the womb into three classes; the first and most frequent of which produces general disorders; the second, general and local, while the third causes neither. He rejects all operations until a faithful trial has been made of other means for the cure of the disorders arising from the tear. But, if these fail, he substitutes for the suture amputation of the neck. This is certainly one of the strangest of recent professional vagaries, and needs but to be stated to insure its general condemnation.

SPECIAL ARTICLE.

FERRÁN'S CHOLERA INOCULATIONS.

PROF. VAN ERMENGEN contributes to the *Deutsche medicinische Wochenschrift*, of July 16th, the following report of his visit to Spain to investigate the cholera inoculations as practised by Dr. Ferrán.

Permit me to premise, he says, that my mission to Spain has not been so successful as I anticipated. The obscurity which surrounds many of the so-called inoculations I am unable to clear up. I trust, however, that it will be evident that the blame therefor does not entirely rest with me.

I came to Valencia on the 19th of June, in company with my friend Dr. Paul Gibier, assistant at the museum, who, like me, was sent by his government to study the methods of Dr. Ferrán. Our mutual aim, as well as our observations, have resulted in this—that the data which I collected in Spain have been brought together with the assistance and co-laboration of this eminent bacteriologist. I may also say that my conclusions in no matter of importance differ from his.

As Dr. Ferrán was in Madrid at the time of our arrival, we endeavored, first of all, to obtain some certain information as to the character of the epidemic. In the city, as well as in the hospital, we had the opportunity of seeing numerous cases, which were undoubtedly Asiatic cholera of the most terrible form—the asphyxic, dry cholera. Koch's comma-bacillus, in two autopsies, was found in the intestinal fluids, and in the stools of the sick in every case. I send you a culture, three generations in Agar-agar, in which you will recognize that the microbes isolated by us are identical with that discovered by Koch.

We have questioned and examined about three hundred persons who were inoculated and reinoculated. The phenomena which were observed after inoculation with Ferrán's vaccine, may be enumerated as follows: About five hours after the injection on the external portion of the upper part of the arm there appears an œdematous swelling, somewhat painful and ordinarily with little extension of swelling. This disappears in from twelve to twenty-four hours without leaving any traces or scar. At the same

Digitized by Google

time there are observed symptoms of fever, malaise, chills, and a kind of stupor—symptoms which soon pass away and are always proportional to the local inflammatory action. In rare cases (about two or three) two or three liquid stools were observed without specific character. There were no pains or persistent cramps, but sometimes transient contractures. None of the cases observed showed symptoms even suggestive of algidity.

Blood taken from the index finger twelve hours after inoculation, in six tests was normal and contained no micrococci or bacteria. Even at the seat of the œdema—a centimetre from the periphery, the appearance of the blood was normal. In plate-cultures some drops in 10 cubic centimetres of 10 per cent. nutritive gelatine, there was no development of microörganisms. The liquid stools which one of the inoculated individuals afforded, we were unable to investigate.

The individuals who were subjected to revaccination with the second vaccine presented the same local symptoms. The latter appeared to us, ordinarily to be less severe, but it is probable that the method of inoculation which is distinct in each case, is the cause of the difference observed. The first vaccine was inoculated in our presence by deep injection into the muscular tissue, while the point of the hypodermic needle was inserted almost perpendicular to the bone deep into the arm. The method of reinoculation was, as we have found, the same as is ordinarily practised, by which the fluid is injected through a fold of the skin into the connective tissue.

I must add that we did not observe that the slightest precautions were taken to prevent the access of the germs from the air to the vaccine fluid. The vaccine was kept in an unsterilized cup, and was protected from air germs only by a single sheet of blotting paper. The syringe itself was sterilized, as it was called, by drawing a little boiling water through it. Dr. Ferrán neglects all the precautions which are observed in the laboratory in the inoculation of the lower animals. We should not, therefore, have been surprised if we had seen septicæmic appearances follow the inoculations, confirmatory of the reports which lately appeared in the *British Medical Journal* and *Deutsche med. Wochenschr.* I must, however, say in the interest of truth that in no case did we observe abscess or suppuration as a result of the vaccination. Scrupulous investigation concerning a case reported in Alcira, convinces us that the confidence of the correspondent of the *British Medical Journal* was abused. The Chinaman whom he there saw, was seized with cholera without having been vaccinated. A woman, the sister of Dr. Serra, in whom the reporter of the article in question had observed the development of gangrenous abscesses, suffered nothing else than a slight suppuration, which now has left a scarcely perceptible scar. In a letter in *las Provincias* of June 26th, a journal of Valencia, our esteemed correspondent from Alcira assures us that only seven or eight cases of abscess occurred in 10,000 inoculations. Ferrán denies responsibility for these and attributes their occurrence to negligence on the part of his assistants.

Alcira was the first region which the present epidemic of cholera visited. The town is situated upon an island which is formed by the meanderings of the river Jucar. The surroundings are in the highest degree conducive to that insalubrity which is specially noticeable in sundry regions of this portion of Spain. The influence of the water in causing the spread of the disease appears indisputable. As soon as the inhabitants began to drink water from a spring at some distance from the town, the epidemic decreased notably in intensity. The register of inoculation statistics and their results were furnished by the Spanish magistrates. In Alcira from the 18th of May to the 25th of June, 10,000 persons were inoculated—a number representing one-half of the population, which can be estimated at from 20,000 to 25,000—while the latest official census gives only 16,000. The cholera in two months claimed 130 victims—of whom 120 were not vaccinated, and ten had been vaccinated once or twice. This in comparison with other localities, as Burjasol, Murcia, etc., is an extremely small mortality, and shows, with far-reaching significance, that the statistics of Alcira were made to demonstrate the utility of Ferrán's vaccinations. We could obtain no detailed information concerning the social standing of the inoculated and the non-inoculated, concerning their age and sex, and concerning the time when the inoculations took place. It seems probable that the inhabitants of the better classes were vaccinated in great numbers, and for about a month.

In Algemesi, Alberique, etc., the statistics are still less significant.

I now come to the most difficult part of my investigations.

We must next convince ourselves of the presence of Koch's comma-bacillus in Ferrán's culture fluid. A drop of the fluid taken from one of eight balloons which were for the second vaccination enabled us to confirm the presence of Koch's bacillus, unmixed with other organisms. The bacilli were rather sparse, slender, and very small. And there existed none of the forms of development such as Ferrán claims to have discovered. In plate cultures we confirmed the presence of numerous small colonies of normal appearance. We observed that Ferrán's culture fluid was not very favorable to the development of cholera microbes, and that those which were in it quickly perished.

Dr. Ferrán later was very anxious to show us in older cultures the foreign forms which he had discovered in the cycle of development. He exhibited to us in bouillon fourteen days old, and much changed in appearance, voluminous mulberry-shaped bodies, which were five, or even ten times as large as a blood-corpuscle, which he assumes arise directly from endogenous spores of the comma-bacillus! These masses (Ferrán's mulberry-shaped bodies) resemble the concretions produced in uric acid salts by artificial change, and are readily dissolved in great part by hydrochloric acid and acetic acid. Other round, but less voluminous corpuscles which were found in the liquid, correspond, according to Ferrán, with free spores that had not developed so much. It is super-

Digitized by Google

fluous to say that these forms of impurity are to be ascribed to an origin entirely different. The morphological studies which I undertook under the direction of the author, which he described and illustrated in the *Zeitschr. für klin. Med.*, 1885, led to no result. Ferrán asked more time than we had at our disposal to show us the several forms, and it seemed superfluous to us to pay further attention to the matter.

Even less did I have opportunity to study with Dr. Ferrán the globular masses to whose existence in stages of development of the comma bacillus I first called attention, and which I to-day still consider forms of development, and which are entirely distinct from the exaggerated changes which occur in the exhausted cultures. These are the forms which Ferrán has falsely pointed out as oögenous and oöpherous. I have, in my work, *Researches Concerning the Microbes of Cholera*, already considered these, and think, with my colleague and friend, Dr. Hueppe, of Wiesbaden, that they are very probably reproductive organs and which may be compared with the arthrospores.

I was very much surprised to see that Dr. Ferrán made no use of the perfected means for microscopic investigation of bacteria in the delicate morphological researches with which he was occupied. And every body will be the more astonished, as was I, when I say that he possesses no objective with homogeneous immersion, and Abbé's condenser, and that he omits to stain the bacteria which he studies. His methods of culture, also, are not beyond criticism. However, in order not to digress too widely, I will not make further reference to such points.

We submitted to Dr. Ferrán a series of questions in writing, the solution of which seemed to us indispensable before proceeding experimentally with the procedure which Dr. Ferrán employs in the preparation of his vaccine. To our great regret, Dr. Ferrán declined to answer these questions. He sent us word that it did not seem to him that the time had yet come to publish "his secret," and that he, in his own time and in his own work, would announce the same, and that this was lying in readiness to be sent to the Academy of Science in Paris.

This decision, which simplified our mission in such an unexpected manner, compelled us to abandon the further study of an arranged series of control-experiments. We are compelled to announce that we then requested Dr. Ferrán to supply us with a sufficient quantity of vaccine to carry out a series of experiments upon ourselves and upon animals. We had undertaken to institute comparative experiments concerning the operation of sterilized vaccine, or in that freed by filtration from microörganisms—in contrast with that subjected to no such measures—and we pointed out to Dr. Ferrán that these experiments would in no way render it possible for us to reveal his secret, which he wished to guard, in view of its publication *in toto*.

I may here add that the method of attenuation has already been given me by Dr. Ferrán himself by letter, and apparently consists in cultivating the degenerated microbes in a long series of cultivations of bouillon mixed with gall. We promised Dr. Ferrán, so far as the method of attenuation was new and different from that known to us, to pledge ourselves in writing not to reveal it before receiving permission from him, but without result. In the light of such treatment, which probably is not entirely without precedent in bacteriological science, we took our departure from the Spanish bacteriologist. The experiments which we were prevented from making in Valencia are in progress at the laboratory of the Museum for Comparative Pathology in Paris, and I shall probably report them at another time.

REVIEWS.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN. By S. WEIR MITCHELL, M.D. Second edition, revised and enlarged, with five plates. Philadelphia: Lea Brothers & Co., 1885.

WE are glad to welcome a new and revised edition of this work, which occupies a unique position among treatises on the nervous system. It is the outcome of an experience singularly rich in those obscure and complex hysterical affections so grievously troublesome to the ordinary practitioner and so difficult to combat by ordinary therapeutical means. Thirteen of the seventeen chapters are devoted to the manifold forms and phases of hysteria, two to chorea, one to tremor, and one to chronic spasms. Three new sections have been added: On Hysteria and Organic Disease of the Spine; On Hysterical Joints; and On the Rectum and Defecation in Hysteria. A remarkable case is recorded of hysterical knee with plastic infiltration of connective tissue outside the capsule, which, as the author remarks, is full of instruction to those who believe that hysteria never gives rise to organic changes. The case reported in Lecture XIV. is of unusual interest, showing how completely hysteria may simulate profound organic disease of the spine—in fact, all the features of local myelitis and degeneration were present, and yet under appropriate treatment the patient recovered completely. The concluding lecture is upon the management of these severe cases by seclusion, rest, massage, and feeding—a method which, rightly carried out in appropriate cases, has proved so remarkably successful in the hands of the author and others.

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, June 4, 1885.

THE PRESIDENT, B. F. BAER, M.D., IN THE CHAIR.

BINIODIDE OF MERCURY AS A DISINFECTANT IN OBSTETRICS.

DR. E. R. BERNARDY said that his attention was first attracted to the use of the biniodide of mercury as a germicide by Dr. Miquel, who published in *L'Annuaire Meterologique de 1884*, the results of some experiments made to determine the minimum amount of a disinfectant necessary to prevent fermentation in a litre of sterilized beef-broth. His experiments show that the mercurials are the best antiseptics, the biniodide being nearly three times as strong as the bichloride. In his

Digitized by Google

table of disinfectants, he places the bichloride the fourth on the list. To a litre of sterilized beef-broth, he found it required 0.025 gramme of the biniodide of mercury to keep the broth pure; while 0.070 gramme of the bichloride of mercury was necessary to produce like effects. This shows that bacterial life is impossible in a solution of one-forty-thousandth part of the biniodide, while of the bichloride it requires the one-fourteen-thousandth part. I was so forcibly impressed with his experiments that I determined to give the biniodide of mercury a trial in obstetric cases where it would be necessary to use an antiseptic. The following are the cases in which it was used.

Case I.—On February 7, 1885, I was requested to take charge of Mrs. I., who had been confined about six weeks previously. It had been her second confinement, the duration of labor had been short and delivery natural, but an extensive laceration of the perineum had occurred. No attempt had been made to bring the parts together by sutures. On the third evening she had been attacked with severe frontal headache and chills, followed by fever with great tenderness over the region of the uterus. There being no improvement in her condition, her medical attendant was discharged, another called in, who gave such an unfavorable prognosis, that he also was requested to cease his attendance. I was finally called in on the above date. The patient had well-marked symptoms of septic poisoning, pulse 130 to 140, small and thready, and disappearing under pressure of the finger; temperature 104°–105°; slightly delirious, constant vomiting, abdomen swollen and excessively tender; uterus enlarged, extending fully three inches above the pubis. In the right side there seemed to be a growth extending up into the abdomen, tender on pressure. On making a vaginal examination, I found the os dilated so that my index-finger could readily enter the uterus. Its withdrawal was followed by a gush of highly offensive matter. The uterus was surrounded by organized lymph, and was immovable. The mass on the right side was easily detected, and was continuous with the lymph surrounding the uterus. The vagina was hot. The perineum was torn to the anus; the surface raw and secreting an acrid matter, which scalded the surrounding parts. The urine was dark, on straining a reddish material settled to the bottom, it looked like blood-corpuscles. Dr. A. E. Roussel examined the specimen and reported it to be slightly acid, no albumen or sugar; under the microscope, occasional pus-corpuscles, and swarming with bacteria. In conjunction with internal treatment, intrauterine injections were made three or four times a day. I first used a solution of bichloride of mercury one to two thousand. This was continued for three days without any marked results. The discharges continued as offensive. On the fourth day the bichloride was discontinued and replaced by a one to four thousand solution of biniodide of mercury. Within twenty-four hours an amelioration of all symptoms took place, the pulse fell to 100, temperature to 101°, urine became clear, and the discharge odorless. The injections were continued for ten days, their frequency being gradually reduced. The uterus returned to almost its normal size and the lymph was gradually absorbed. The patient recovered.

Case II.—March 19, 1885, I was called to attend Mrs. W. in her first confinement. On my arrival, found she had been in labor several hours. Examination showed the os perfectly dilated, bag of water protruding, vertex presentation, first position, ruptured the amnion. The vagina near its outlet was roughened with venereal warts; these spread also over the vulva. Labor progressed rapidly, and the second stage was happily ended. After waiting nearly an hour, making compression on the uterus, I made slight traction on the cord, and while doing so, felt, with my hand upon the uterus, a cup-like depression of the fundus take place. This convinced me that I had an adherent placenta to deal with, and it would be folly to wait any longer. On introduction of the hand, I found the placenta completely adherent; one could hardly say which was uterus, which placenta. After considerable trouble I at last succeeded in detaching the placenta; it took fully an hour. On making a second examination to ascertain if all had been removed, my hand came in contact with long shreds hanging from all sides of the uterus; the more I scraped, the more there seemed to be. I gave the patient f℥ij of the extract of ergot. The patient did well for two days, when, toward evening, she complained of a chill and severe frontal headache. I gave her quiniæ sulph., gr. x, with morph. sulph, gr. ¼, at one dose; washed out the uterus with a 1 to 4000 solution of biniodide of mercury. The pulse was 115, and temperature 102°. The discharge was highly offensive. The injections were repeated every four hours. On the evening of the next day the pulse was 98, temperature 100°, discharge odorless, and the patient was perfectly well in ten days more.

Case III.—April 23, 1885, I was requested to call at once to see Mrs. K., who was reported in imminent danger of death; this was her ninth confinement. The history of the previous ones, with one exception, was not good. Her labors were natural, but were followed by terrible flooding and protracted convalescence. I found the patient in an attack of puerperal convulsions. I gave at once grs. xxx of potass. bromide and grs. xx of chloral hydrate. This dose was repeated in half an hour. Ten minutes later another convulsion occurred. I then bled the patient freely. The os uteri was somewhat enlarged, the cervix soft and dilatable, vertex presentation. Dr. Curtin, whom I had sent for, having confirmed my opinion, and considering that the patient's time was quite up, we decided to etherize, dilate the cervix, and deliver. The forceps were applied, and traction made at intervals. A living child was safely delivered. Continuous pressure was maintained over the uterus; but, after the expulsion of the placenta, the uterus did not contract until it had been washed out with hot water. The bromide and chloral were continued every two hours, and no more convulsions occurred. The patient did well up to the fourth day, when the discharges became very offensive, the pulse accelerated, and slight tenderness existed over the uterus; no chill or fever. The uterus was thoroughly washed out with a solution of the 1 to 4000 biniodide of mercury. Within twenty-four hours the discharge became odorless, and the tenderness over the uterus had disappeared. The patient recovered after a tedious convalescence.

In these cases it will be seen that the biniodide was prompt in its action, markedly so in Case I., where the bichloride and the biniodide were both employed, the

Digitized by Google

result being decidedly in favor of the biniodide. Naturally it will be said: here are only three cases from which deductions are to be drawn, and yet it is only after it has been carefully used in a large number of cases that its efficacy can be proved. It is for this reason that I call the attention of the members of this Society who are in a position to give it a fair and impartial trial, and at some future time give the results of their investigations. I have found the 1 to 4000 solution of the biniodide non-irritating. I have used it extensively in my gynecic practice, and in washing out pus cavities, with good results. In it we have a preparation where the smallest amount of drug is used with results far exceeding those of any other antiseptic. On account of the small quantity of mercury, there will be less chance of salivation.

The method I have pursued in making the solution is: Take three and a half grains of the salt, well triturated in a mortar, and rubbed with one quart of boiling water, slowly added, giving a solution of 1 to 4390.

Since writing the above, I have seen in the Philadelphia *Medical Times*, May 16, 1885, that H. Panas, Eye Surgeon of the Hôtel-Dieu, uses the 1 to 25,000 solution of biniodide of mercury in eye cases. He makes the following statements: "After a number of experiments, I have convinced myself that a solution in water of 1 to 10,000 of the bichloride, or a similar solution of 1 to 25,000 of the biniodide of mercury, is much superior to any other antiseptic solution employed in eye surgery." Here again we have a statement that the biniodide in a smaller quantity is as good an antiseptic as the bichloride.

DR. MONTGOMERY'S experience has led him to the conclusion that the bichloride of mercury is far more effective as a disinfectant than carbolic acid. Its introduction into the Philadelphia Hospital was due to Dr. Parvin, who found it very satisfactory. In eighteen cases of puerperal fever that were treated with bichloride injections only three deaths occurred. This success was attributed by the hospital staff to the use of the bichloride. Dr. Montgomery, in private practice, follows the plan of Dr. Garrigues, of New York, and avoids intrauterine injections after labor, but applies pledgets, wet with a bichloride solution, over the vulva, after carefully cleansing away clots and washing the external parts with a similar solution. This sponging is repeated twice every day. In his last term at the Philadelphia Hospital he had only two cases of puerperal fever, one of which commenced twelve days after delivery. The history of Dr. Bernardy's cases shows an equal, if not better, antiseptic in the biniodide of mercury.

DR. J. V. KELLY, some years ago, had several cases of puerperal fever, and about twenty-five cases that got well. The trouble commenced in a case of abortion, in which he did not succeed in removing all of the placenta. He was at the same time attending a bad case of erysipelas, and at that time the relationship of puerperal fever and erysipelas was not known to him. He was on the point of giving up his practice and leaving the town, and he consulted Dr. Goodell on that question. Dr. Goodell discountenanced such action, but advised him, when attending an obstetric case, to remove his coat and roll up his sleeves, and wash his hands and arms well with turpentine, using the nail-brush thoroughly. Since that time he washes his hands in turpentine every day, and again before every case of labor. He also uses a wash of vinegar or carbolic solution before touching a puerperal patient. He has had no puerperal fever or other septicæmic symptoms since that time.

DR. PARVIN said, as a reference had been made by Dr. Montgomery to his having used corrosive sublimate vaginal injections in the cases of puerperal septicæmia under his care in the Philadelphia Hospital in his term of service last year, he would refer to the antiseptic treatment in the cases occurring the present year. When he took charge of the obstetric ward on the 1st of January, he found five recent cases of septicæmia. Two of these patients died. One of the two had apparently recovered, and then was attacked by pneumonia; quite possibly this pneumonia had a septic origin. Then there were at least seven other cases; but all these, as well as three of the original five, recovered. Injections of a solution of corrosive sublimate, 1 to 5000, were used; in all cases immediately after labor. The external parts were washed, too, with a similar solution. This injection was repeated twice a day, in all cases for the first week after labor; while it was used oftener in those having septicæmia. Intrauterine injections were used only when vaginal injections failed to correct the effusiveness of the discharge. But, as is well known, there may be serious, even fatal cases of septic disease, though the lochial flow is not at all offensive.

In private practice, after once washing out the vagina thoroughly with the antiseptic solutions immediately after labor, this need not be repeated unless symptoms demand it; but the bathing of the vulva twice a day with the solution ought not to be omitted. Add, if you please, to this treatment the use of antiseptic napkins, a practice pursued by Dr. Montgomery at the Philadelphia Hospital so successfully, and I think we have taken the most important means to guard against the entrance of septic germs after labor.

He has had no experience with the biniodide of mercury, and does not know that it will supersede the bichloride. The argument in its favor is as strong as these successful cases can make it; but these are entirely too few, as Dr. Bernardy justly says, to prove its value and its superiority. In one of the doctor's cases labor was induced, apparently, on account of eclampsia. Now, is this the best treatment? Obstetricians are by no means agreed, some of the best condemning such treatment. But the subject is not properly before us now, and therefore no further remarks will be made upon it.

DR. MONTGOMERY uses the bichloride solution as an external wash only, not as an injection. He thinks the records of the hospitals in which injections are used will not show as good results as those in which they are omitted, if septicæmia be not present.

DR. WILLARD had a warning to sound with regard to the use of bichloride solutions of stronger grades. He had been using washes and antiseptic dressings made with a 1 to 1000 solution of bichloride; but, in consequence of what was written about the advantages of stronger solutions, he increased the strength of his dressings to 1 to 500, and within twenty-four hours the stools contained bloody mucus, and were small and griping; there was vesication about the wound and around the limb under the dressings. Entirely dry dressings had been used, but they had been moistened

Digitized by Google

by pus and serum from the wound. He does not see the advantage of using strong solutions in serum, as 1 to 100 or 75. The serum is a decomposable substance, and an uncertain portion of the antiseptic agent is destroyed by it. Weak solutions in boiled water seem more reasonable and answer every purpose.

DR. LONGAKER has been much interested in the third stage of labor, and would like to hear how Dr. Bernardy removed the placenta in the adherent case narrated by him. He has been using Credè's method with great satisfaction. He thinks the hand should be kept out of the parturient canal as much as possible. He does not use vaginal injections after labor, but depends upon outside washes. He finds that the temperature rarely rises during the puerperal period, even after instrumental delivery. He thinks care during the third stage will avoid the necessity for antiseptics.

DR. PARISH agrees with Dr. Parvin's views. He has found a solution of 1 to 1000 of bichloride irritating, and he now uses 1 to 2000 or 5000. Strong solutions cause an appearance resembling erysipelas or inflammation of the derma. Injections are not necessary in every case; when the surroundings are cleanly, and the patient a multipara, he does not use them; but in primipara with contusions or lacerations, and when version or instruments have been employed, he is in the habit of injecting a weak solution of bichloride, especially after delivery; he does not repeat it, but simply washes out the vagina; cleanliness of hands, instruments, and nurse is the most important point. He has never had any trouble in private practice.

DR. BERNARDY, in closing the discussion, remarked that he thought he had a far better antiseptic in biniodide than the bichloride. He had used the former in surgical cases also, washing out pus cavities, and always with good results. He does not use intrauterine washes in every case of labor. He has attended since the first of the year about seventy cases of labor, and he has employed the intrauterine injections in only the three cases detailed. In every case of labor he uses carbolic acid soap to cleanse his hands and arms and the external genitals of the patient. The eclamptic patient had reached or passed her full term, and there was no reason why the child should not be removed. In the case of adherent placenta it was pulled off forcibly, and a shreddy lining was left in the uterus, as no line of separation had formed. He believes the dangers consequent on passing the hand and arm into the uterus and vagina are much exaggerated, and he does not hesitate to do so when the exigencies of the case demand it.

NEWS ITEMS.

MORE WITHDRAWALS FROM THE CONGRESS.—We are requested to announce the following declinations of office under the new Committee: Drs. Hunter McGuire and S. P. Moore, of Richmond, Va., as Vice-Presidents of the Section of Military and Naval Surgery and Medicine, and Dr. James B. McCaw, of Richmond, Va., as Vice-President of the Section of Medicine; Dr. Le Grand N. Denslow, of St. Paul, as member of the Council of the Section of Dermatology and Syphilis.

We are informed that Dr. John L. Atlee, of Lancaster, has declined his appointment as Vice-President of the Congress, and that Dr. Joseph R. Smith, U. S. A., has declined to serve on the Council of the Section of Public and International Hygiene; Dr. E. S. Dunster of Ann Arbor, on the Council of the Section of Obstetrics and Gynecology; and Dr. Henry Sewall, of Ann Arbor, on the Council of the Section of Physiology.

THE DALLAS COUNTY (TEXAS) MEDICAL SOCIETY AND THE INTERNATIONAL MEDICAL CONGRESS.—The following preamble and resolutions were adopted by the Dallas County (Texas) Medical Society, in special session convened, July 25, 1885. The President S. D. Thurston M.D., in the Chair.

Whereas, The American Medical Association at its meeting in Washington City, in May, 1884, recognized a general desire of the medical profession of the United States, by adopting a resolution under which a committee was appointed whose duty it should be to extend an invitation to the International Medical Congress, shortly to assemble at Copenhagen, to hold its next meeting in 1887 at Washington City, D. C., and

Whereas, The said Committee, by the letter and spirit of this resolution, was fully empowered to act, not only as a Committee of Invitation, but as an Executive Committee as well, and

Whereas, The said Committee in pursuance of the objects of the above-mentioned resolution, and duly exercising the unlimited authority delegated to it, enlarged its membership and otherwise provided for the successful holding of an International Medical Congress at Washington City, in 1887, all of which arrangements were considered by us as judicious, and, contrary to what has been charged by some, wholly disinterested as to personal or local aggrandizement, and

Whereas, The American Medical Association at its last meeting at New Orleans, did, in our judgment, unwisely and untimely, virtually rescind its former action, which reactionary movement has deranged, if not indefinitely suspended, the work of the original Committee which was satisfactorily progressing, and created an indifference to the Congress among recognized leaders of medical thought and interest throughout the country, and

Whereas, There are those who persist in urging the so-called justice of their claims for the organization of the International Medical Congress on a territorial basis, which unfortunate idea has been unwisely further extended by some members of the profession in Texas in a manner calculated to arouse a sectional prejudice, which has little, if any, existence in our State; therefore be it

Resolved, That the Dallas County Medical Society deplores what must be considered the present interregnum in the affairs of the contemplated International Medical Congress, brought about, as we believe, by an ill-considered and hasty action at the New Orleans meeting before mentioned; that this Society was fully satisfied with the work of the original Committee, which was composed of able, eminent, and conscientious members of the profession; that this Society repudiates any attempt to inject a sectional feeling into a purely professional matter which has reference to scientific investigations only, and that said attempt, if offered in behalf of the medical profession of Texas, is, in the opinion of this Society, both unauthorized and gratuitous; and

Digitized by Google

that looking beyond a narrow-minded policy of personal aggrandizement and sectional interest, we heartily commend the recent action of Philadelphia and New York brethren, as well as those elsewhere, who have retired from the Congress until a more dignified and unselfish view of the arrangements can be had; and we pledge them our hearty support and good will in their efforts to advance the interest of the American medical profession in future meetings of International Medical Congresses, where the truly representative medical abilities of our country shall be enlisted uncontrolled by geographical lines or personal preferences.

"THE ACTION OF THE AMERICAN MEDICAL ASSOCIATION ENDORSED."—We have before us a circular with the above heading, which, we are informed, has been widely circulated throughout this State. It is signed by Drs. Wm. H. Pancoast, Wm. B. Atkinson, and P. D. Keyser, and is as follows:

"The action of the American Medical Association, at its meeting in New Orleans, in April and May, and in the subsequent action of its Committee at Chicago, in insisting that only those in accord with the National Code of Ethics should become members of the Ninth International Medical Congress, to be held in Washington, D. C., in 1887, is most heartily endorsed; and we will personally do all in our power for the success of the Congress."

Appended to the circular is the request that, if it meet with approval, it be signed and returned to Dr. Pancoast's address.

THE SPECIAL MEETING OF THE COMMITTEE OF THE AMERICAN MEDICAL ASSOCIATION ON INTERNATIONAL MEDICAL CONGRESS.—We are informed that "The Committee appointed in accordance with resolutions passed at New Orleans, will meet in special session for the transaction of urgent business" at New York on September 3d.

PUBLIC OPINION ON THE CONGRESS ORGANIZATION.—So rapidly did the new nominees in one city after another—Philadelphia, Boston, Baltimore, Washington, and Cincinnati—declare that they would take no official part in the Congress under the new organization, that it became evident that the undertaking was doomed to ignominious failure unless a complete reversal of the New Orleans action could be secured. We have for some time been convinced that nothing short of that would satisfy the profession and restore any reasonable hope for the success of the Congress. We have felt, too, that this end was most likely to be accomplished by getting as full and prompt an expression as possible of the feelings of the profession. Of late it has looked as if these withdrawals, which at first threatened to confirm the wreck of the Congress, would really lead to the radical remedy we have mentioned.—*New York Medical Journal.*

The fact is unmistakable that the present organization of the International Congress seems gradually falling to pieces. Its best and most representative men have withdrawn. Opinions from the other side show that no confidence or sympathy will be felt in the position taken by the American Medical Association. It is useless to deny that, unless something radical is done, the Washington Congress will be simply a humiliation of American medicine before the world.—*New York Medical Record.*

Seldom has there been such unanimity of opinion upon any matter as we have seen expressed in the medical journals of this country on the proposed International Medical Congress. We need not repeat in detail the well-known story of the appointment of the original Committee by the American Medical Association, with plenary powers to prepare for the meeting of the Congress in 1887; of the opposition which the printed provisional list of officers and members of the Congress met with; of the movement set on foot to reorganize the original Committee, and thus give an opportunity for the admission of some of the discontents to positions in the Congress; of the reorganization of the officers and councilmen of Sections in Chicago in such a way as to distribute the appointments over a larger area of the Union, not failing to "punish" (as they say in politics) original members who had condemned the New Orleans movement, or were New Code men; how some of the active dissentionists were supplied with prominent places in the new organization; how the leaders of the original Committee were compelled by self-respect to resign, and the most prominent members of the original body in Baltimore, Philadelphia, and Boston, promptly withdrew their names, thus withdrawing from the Congress a considerable number of the ablest men in the country. It is a record painful to make, not only because it means that the Congress cannot now possibly be what it could have been under the first organization, but because it shows how large a share of medical politics can enter into the meetings of such a loosely constructed body as the American Medical Association, when designing members choose to exert themselves.—*North Carolina Medical Journal.*

That the recent action of the American Medical Association is sustained by parliamentary usage, does not in any way commend the expediency of its course in view of all the facts. An executive committee of seven most assuredly afforded a better prospect of efficiency in making "all necessary and suitable arrangements for the meeting of such Congress" than one of forty-five members, such as provided for, with the addition of thirty-eight to the original committee under the resolutions of 1884.—*Atlanta Medical and Surgical Journal.*

What will be the outcome of this deplorable muddle it is altogether impossible now to say. The Committee, aided by older and wiser heads than those who have hitherto directed its movements, may look back and find a path which will lead the Association out of its present dilemma, and up to the point of organizing a truly International Congress, alike worthy of its noble aims and of the great guild which bids it come to our land. If the Committee fails—especially if it fails through unworthy ambition, love of patronage, or, worse than all, through greed of office—it will realize before the business is finished, that wreckers are sometimes wrecked, and revolutions are often fatal to their leaders.—*American Practitioner.*

The policy of the Committee was broad and liberal, recognizing representatives of American medicine, regardless of residence and difference of opinion on matters of purely local interest. The Committee appointments, therefore, were made regardless of mem-

Digitized by Google

bership in the American Medical Association and without respect to differences on questions of medical ethics. After all, the International Medical Congress, organized in the interest of medical science and medical philanthropy, feels no concern whatsoever in the professional policy or politics of the country where a meeting may be held. The work of the Committee, under the circumstances extremely delicate and difficult, was practically well done and, in the main, acceptably, we believe, to the American profession, as well as to a majority of the members of the American Medical Association. However, there were murmurs in various quarters.

Some complained of the Committee for exercising unwarranted authority. However this may be, we believe the Committee acted in good faith and in the interest of the International Congress. The language of the resolution, under which the Committee was constituted, is certainly very wide in its scope and may easily be interpreted as granting full executive power.

Others thought the Committee wanting in propriety to elect its own members to the most exalted positions in the organization. Why should the Committee have gone beyond its own membership, we ask, when its personnel comprised names historical in American medicine, honored by their countrymen and respected abroad?

More objected to the appointments of the Committee on the ground of an unequal sectional representation. "The North, the South, the East, and the West" were arrayed as if we were in the midst of a presidential canvass. This argument had its effect upon a few inflammable minds, but, fortunately, devotees to the science of medicine are not hedged in by sectional lines. We favor the appointment of men who represent American medicine, wheresoever they may reside, whether in the empire of Texas, in California, or in the cities of the East.

The real cause of all this discord arose from a feeling perfectly natural among men struggling for personal or professional preferment. There were not offices enough to go all around, and for this reason only, many men of unquestioned merit were excluded from official connection with the Congress. The justice with which some others were excluded we now realize more fully, since they have demonstrated so clearly their own unfitness for high official positions.

Already, it is painfully evident that it is simply impossible to organize the American meeting of the International Medical Congress upon the plan adopted by the Chicago Committee. Truly, we stand to-day a divided household, and unless some reconciliation can be effected, the failure of the Congress is inevitable.—*New Orleans Medical and Surgical Journal.*

The progress of another week presents a wide-growing distrust of the recent work of the Committee at Chigago. The withdrawal of the appointees of the Committee in Philadelphia, Boston, Baltimore, and Washington has been followed by similar resignations in Cincinnati, St. Louis, Chicago, and in other localities. These declinations have come not only from the gentlemen originally appointed by the first Committee, but, in a number of instances, the appointees of the present Committee respectfully decline to hold the honors awarded to them. Indeed, it seems to be quite apparent that the gifts of this Committee will go begging unless some unseen power is raised up to prop its waning fortunes. Under existing circumstances it seems clearly the duty of this Committee to abandon its work of reorganization as the most graceful and practical solution of the difficulties which embarrass it. By such a course the Committee would in no sense lose the respect of the American profession. It has been placed in a false position by the American Medical Association. It has been called upon to perform a duty which no similar Committee of the Association can perform under existing circumstances. The present status of the Congress is the result of a false and unnecessary issue which can work no good to the American profession or to the American Medical Association. Its introduction into this discussion was totally unwarranted and unjustifiable. The "Code" issue is not an issue which should be raised in the organization of an International Medical Congress. At previous meetings of the Congress all questions of medical politics have been rigidly excluded, and such should have been the case in the organization of the present Congress.—*Maryland Med. Journal.*

Perhaps it would have been just as well, in the interests of the Congress, had the New Orleans meeting left well enough alone. Unless the *status quo* of the Committee and its appointees before the New Orleans meeting be restored, the prospects of the Congress must be very gloomy. And its restoration is, of course, out of the question, for it behooves the American Medical Association to be consistent above all things, and, besides, it will be difficult to make it understand that its treatment of the original Committee and of the American medical profession, has been anything but eminently fair, honorable, and courteous. Many men of many minds.—*Medical Age* (Detroit).

We had supposed that the meeting of the American Medical Association recently assembled at New Orleans would gladly endorse the acts of its Committee, and say, Well done! Go on and complete the work you have so well commenced. But no, says a narrow clique of agitators, you have left certain States unrepresented, you have neglected the rural districts, and, worse than all, you have ignored a number of us bumptious soreheads, who are superlatively well qualified for the most responsible positions in the Congress. By some means a majority of those present were induced to vote for a resolution which practically censured the Committee, and added enough new men to govern the organization for the future.

We cannot help thinking that the method of procedure was, in all respects, unmanly, ungenerous, and unjust; and we sincerely sympathize with that large portion of the respectable body of the profession in the United States, who must feel keenly the humiliating position in which they have been placed. Already this sad business is bearing its bitter fruit. The respectable physicians of grand, conservative old Philadelphia have, in a body, formally declined "to hold any office whatsoever in connection with said Congress, as now proposed to be organized."—*Canadian Practitioner.*

The extracts from the American medical journals, which we print elsewhere, will be sufficient to show that the prevalent opinion in the States is, that the Washington Congress is not only in danger, but absolutely doomed to failure. The leaders of the profession, both

Digitized by Google

in Boston and Baltimore, have followed the lead of the Philadelphians, and withdrawn from the Congress, and it is not unlikely that their example may spread to other cities, though, indeed, enough has already been done to turn the meeting of 1887 into what an American contemporary, drawing its illustration from our common history, appositely terms a "rump" Congress. The only hope is that the American Medical Association will be startled back to its senses by the strong and decisive action of the profession in Philadelphia, Boston, and Baltimore, and will make haste to retrace its steps. It may be taken for granted that not even the leaders of the malecontents, and certainly not the members of the Association at large, realized that the results of their action would be destruction to the Congress of 1887, and danger to its successors. Such an event was probably far from their calculations. They simply reckoned without their host, *i. e.*, their leaders, and if they are wise, they will cast another reckoning, this time with due regard to the said host.—*London Medical Times.*

The most recent advices from the United States have brought the startling intelligence that there exists in the American medical profession a very serious discord concerning the next International Medical Congress. We do not propose to discuss the etiology of this rupture, for it is quite enough to be called upon to face the fact that it exists. The fact is very grave. Its existence jeopardizes, if it have not already destroyed, the probable success of the forthcoming Congress. Certainly our brethren in the States cannot expect those who have already promised to attend and those who may expect to visit America at that time, to work with enthusiasm in the preparation of any scientific contribution while those whom they propose to visit are divided, and while wholesale secessions of the official executive and of well-known persons nominated to high offices are announced. Nor do we consider it to be either our duty or privilege to suggest a remedy for this exceedingly unpleasant dilemma. It seems to be conclusive that the profession in American at this moment is hopelessly divided on the subject. Already a large proportion of the influential and active scientific men of Philadelphia, such as Bartholow, Weir Mitchell, Da Costa, H. C. Wood, Pepper, Leidy, Stillé, Parvin, and Goodell, and David Yandell, of Louisville, have publicly withdrawn from the organization of the Congress. A like number of distinguished men in New York, such as Loomis, Roosa. Jacobi, Mundé, Agnew, and Emmet, have also either resigned or been dropped, and therefore will not cooperate with the present organization. The outlook, as the matter now stands, is not at all encouraging. One committee has reorganized the work of another up to the point near that of destruction. Moreover, the work of the present committee must be submitted to the American Medical Association in May, 1886; and no one can say to what extent it may also be either overturned or modified in such a way as to impede seriously the labor necessary to be performed before the meeting of the Congress in 1887. Altogether, the position is lamentable, and there is much fear that the acceptance of the invitation to meet in the States may be withdrawn, and the next meeting of the International Medical Congress be held in Berlin or some other great medical centre, pending the settlement of the serious dissensions among our brethren of the United States.—*Brit. Med. Jour.*

SENTENCE OF EX-SURGEON-GENERAL WALES.—The findings of the naval court-martial, before which ex-Surgeon-General Wales was recently tried, were made public this week. The Court sentences him to suspension from rank and duty for five years, on furlough pay, and to retain his present number in his grade during that period.

Dr. Wales was tried for culpable inefficiency in the performance of duty, and for neglect of duty.

THE ILLINOIS OFFICIAL REGISTER OF PHYSICIANS AND MIDWIVES.—The Illinois State Board of Health is now engaged in revising the "Official Register of Physicians and Midwives." Any notification of changes, omissions, or errors will be regarded as a favor, as the Board wishes to make the coming register as correct as possible.

Address communications to the Secretary State Board of Health, Springfield, Ill.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 28 TO AUGUST 3, 1885.

DE WITT, CALVIN, *Captain and Assistant Surgeon.*—Promoted to Major and Surgeon, vice Bill, deceased, to take effect from July 21, 1885.

IVES, FRANCIS J.—Appointed Assistant Surgeon, with rank of First Lieutenant, to rank as such from July 25, 1885.

GIRARD, A. C., *Captain and Assistant Surgeon.*—From Department of the East to Department of Columbia.—*S. O. 170, A. G. O.*, July 27, 1885.

EBERT, R. G., *Captain and Assistant Surgeon.*—From Department of Columbia to Department of the East.—*S. O. 170, A. G. O.*, July 27, 1885.

TESSON, L. S., *Captain and Assistant Surgeon.*—Ordered from Fort Stockton, Texas, to Fort Davis, Texas.—*S. O. 90, Department of Texas*, July 27, 1885.

CARTER, W. F., *Captain and Assistant Surgeon.*—Ordered for duty as Post Surgeon to Fort Stockton, Texas.—*S. O. 90, Department of Texas*, July 27, 1885.

POWELL, J. L, *Captain and Assistant Surgeon.*—Assigned to temporaty duty at Fort Leavenworth, Kansas.—*S. O. 110, Department of Missouri*, July 30, 1885.

APPEL, A. H, *Captain and Assistant Surgeon.*—Ordered for duty with U. S. troops forming portion of guard of honor over remains of Ex-President General Grant, at Mt. McGregor, New York.—*S. O. 36, Division of Atlantic*, July 29, 1885.

GORGAS, WM. C., *Captain and Assistant Surgeon.*—Granted leave of absence for two months, to take effect about August 10, 1885.—*S. O. 169, A. G. O.*, July 25, 1885

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING AUGUST 1, 1885.

FESSENDEN, C. S. D., *Surgeon.*—Leave extended ten days on account of sickness, July 27, 1885.

GODFREY, JOHN, *Surgeon.*—Granted leave of absence for thirty days, July 29, 1885.

IRWIN, FAIRFAX, *Passed Assistant Surgeon.*—To proceed to Richmond, Va, and Wilmington, N. C., as inspector, July 28, 1885.

AMES, R. P. M., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, July 27, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

VOL. XLVII. SATURDAY, AUGUST 15, 1885. No. 7.

ORIGINAL LECTURES.

SOME FORMS OF MYELITIS, THEIR DIAGNOSIS FROM EACH OTHER AND FROM HYSTERICAL PARAPLEGIA.

Two Clinical Lectures delivered at the Philadelphia Hospital.

BY CHARLES K. MILLS, M.D.,

NEUROLOGIST TO THE PHILADELPHIA HOSPITAL; PROFESSOR OF DISEASES OF THE MIND AND NERVOUS SYSTEM IN THE PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE, ETC.

(Reported by William H. Morrison, M.D.)

LECTURE I.

GENTLEMEN: We have in this great hospital, as those of you who have passed through its wards well know, illustrations of almost all forms of spinal disorder. Atrophies and hypertrophies, scleroses of every name and description, spinal traumatisms and pseudo-traumatisms, diseases functional and reflex, tumors, hemorrhages, and softenings, inflammations of the cord and of its membranes—throughout the whole list, are to be found here. Sometimes cases of almost every type will be within these walls at one time. Many of these forms of spinal disease are incurable. Of the cases which cannot be entirely cured, some, however, can be much benefited by treatment. In a hospital containing so many incurables, care and vigilance must be exercised, or cases that can be cured will be left to lapse to an uncalled-for fate, for want of recognition and treatment. Sometimes in private practice these cases, desperate but not beyond help, are passed by as incurable through ignorance, indifference, carelessness, or lack of thoroughness in investigation. If we had the time, I could give you illustrations of this fact drawn from experience, both outside and inside of the hospital.

The diseases to which I more especially wish to call attention during this and the following lecture are the different forms of myelitis and their counterfeits. I consider this subject of extraordinary importance to the general practitioner, largely because in some of its forms it is frequently a curable affection.

The term myelitis is applied to many disorders—forms of inflammation of the spinal cord. You may have a myelitis which is chronic or acute, which is generalized or localized, which is systemic, or mixed, or compound. You may have, in the technical language of the books of to-day, either poliomyelopathies or leucomyelopathies, which terms simply mean myelopathies, or spinal diseases, of the *gray matter*, from πολιός, "gray," or of the *white matter*, from λευκός, "white." You may have a diffused myelitis. The various forms of sclerosis are considered by some to be special forms of chronic myelitis, by others to be irritant morbid processes, intermediate between inflammation and simple atrophy[1]—but on this branch of the subject I shall not now enter.

[1] Althaus.

The first case which I shall bring before you, is one which has been in the hospital several months. It is an admirable illustration of

DIFFUSED MYELITIS FROM ARSENICAL POISONING.

The notes of the case have been carefully taken by two of the resident physicians, Dr. E. W. Evans and Dr. Alice M. Farnham.

Case I.—M., aged 35, had always enjoyed fair health until nearly one year ago, when, after a prolonged spree, he took a quantity of arsenious acid. Ten hours later, the symptoms of acute arsenical poisoning presented themselves. He was removed to a hospital and rapidly improved as regards the acute symptoms, but one week later he began to notice tingling sensations in the lower extremities. This was soon followed by loss of power in the legs, so that he was unable to stand. With this was associated a sensation as though the skin of the legs was distended with fluid, although no swelling was present. Loss of sensation from the knees downward was absolute.

In the upper extremities neither pain nor disturbance of sensation was present, but paresis, most marked in the extensor muscles of the forearms and hands, caused a bilateral wrist drop. Occasionally he had jerking of the legs, which was more liable to occur during sleep than when he was awake. This condition continued for about four months, when a feeling of formication made its appearance, and since then sensation has been gradually returning.

Three weeks after the poison had been taken, the feet assumed a brownish-yellow hue, and on being soaked, casts of the toes and soles of the feet came away. Desquamation of the hands also occurred, but not to so marked an extent. The finger- and toe-nails presented transverse white lines, but we cannot learn when these first appeared. The nails also became rough and deformed.

He was admitted to this hospital five months after taking the arsenic. General emaciation was very manifest, and wasting was advanced in the legs. The following are some of the measurements which were taken, both sides being practically the same: Thigh, 17¼ in.; calf, 11 in.; arm, 9¼ in.; forearm, 6½ in.

The paralysis of the extensors of the forearms was still marked. Loss of power in the hands was almost complete, but flexion at the elbow could still be performed.

The lower extremities were paralyzed from the knees downward, the patient being entirely unable to move the toes or feet. Movements of the leg on the thigh and of the thigh on the pelvis could be performed. The limbs showed a tendency to external rotation. The feet assumed an equino-varus position. The spontaneous jerkings of the limbs which had been observed at an earlier stage of the disease had almost ceased. At this time, he often complained of pain in the patellar region, which was sometimes so severe as to keep him awake.

Digitized by Google

Desquamation of the hands and feet continued, but not to so marked a degree. The bowels were variable, sometimes requiring cathartics and sometimes astringents. Urine was passed freely and without pain; its specific gravity was 1020; it contained no albumen or sugar. The microscope revealed large quantities of amorphous urates, uric acid, oxalates, and pus cells.

Observations on the temperature of the skin were made, showing, for instance, that on the dorsum of both hands it was 84°, while on the dorsum of the feet it was 90.5° F. The patient usually complained of cold feet.

In some parts of the hand and forearm, the sensibility approached almost to hyperæsthesia. There was anæsthesia of the skin covering the knee, but over the anterior and posterior aspects of the leg sensation was present. In these situations the patient was abnormally sensitive to a pinch. The points of the instrument were indistinctly felt on the feet.

Heat and cold could be distinguished in all the fingers with the exception of the index-fingers of both hands. In testing the feet, it was found that cold could be distinguished in all except the fourth and little toes, while heat was recognized in all but the second toe.

Testing the paralyzed parts with weights, it was found that the feet could not feel the pressure of less than from one-half to two pounds. The right leg required one and one-fourth pounds, while the left could detect one-fourth of a pound, the hand recognizing a weight still smaller.

For three weeks after the acute attack, he had no sexual desire, although evidences of power existed; and both desire and power have since been present.

The morning temperature was taken for ten days after admission and averaged 98°; the evening, 99°, varying from 97.6° to 99.6° F. The pulse averaged in the morning 90 per minute, in the evening 100, varying between 82 and 110, and always being more rapid in the evening.

Investigation of the reflexes showed the plantar and patellar absent in both legs, the cremaster, gluteal, abdominal, and epigastric present, but weak; the scapular reflex about normal, and ankle clonus and gastrocnemial clonus absent.

Farado-contractility was about normal in the arms with the slowly and rapidly interrupted current. In both forearms the slowly interrupted current produced no contraction. With the rapidly interrupted current there was barely perceptible contraction, but the tingling [illegible]tly felt. In the right thigh the contraction to [illegible]as lessened. In the left thigh the reac[illegible]tion [illegible]ormal. No contraction could be produced in [illegible]ight or left leg below the knee, with either the rapid[illegible]ly interrupted current.

The muscles below the k[illegible]sponded feebly to a moderate galvanic current, the reac[illegible]s being markedly those of degeneration.

The patient has decidedly improved in some respects —in the use of his arms, in large movement of the legs, and in sensory disturbances, for instance, but his feet and legs are still paralyzed and show vaso-motor and trophic changes. Testing with the galvanic current, I can get only a feeble contraction, and that at anodal opening. The prognosis is doubtful.

This patient has had a generalized myelitis, an acute diffused myelitis which has become chronic, recovering in large part so far as the upper part of the cord is concerned, and in a less measure in the lower cord.

I present this patient at the start of the discussion of myelitis, because the case is one in which we know the exact mode of origin of the affection, and are able to study in the minutest detail the phenomena presented. The cause of the affection was poisoning with arsenic. About two years ago I gave an account of a number of cases of arsenical paralysis,[1] which occurred as the result of the wholesale poisoning of a family at Norristown, Pennsylvania. One of these was almost the counterpart of the case before you. The patient exhibited extensive paralysis, and reflex, vaso-motor, trophic, and sensory disorders in both upper and lower extremities, similar to and almost as complete as those here presented. He has made a good recovery and is now practising his profession, that of law. I have seen this gentleman within a few days, and the only symptoms left are a slight want of power in dorsal flexion of the feet, and a feeling as if the soles and one half of the dorsal surfaces of the feet were encased.

What I wish most to impress and emphasize with this case before us, are the differential diagnostic features of diffused myelitis, whether acute or chronic. You have here a history and a present condition which show involvement of all parts of the spinal cord in an inflammatory process—symptoms both of irritation and sensory impairment, in the pains, the hyperæsthesia, the anæsthesias, the changes in the power of recognizing pressure, cold, and heat; symptoms also of motor, vaso-motor, trophic, and reflex affections in the twitchings, cramps, paralysis, lowered temperature, nail-bands, mould-like desquamation, abolished knee-jerks, and advanced reaction of degeneration. Bowels and bladder have also been to some extent involved, as shown by the long-continued torpor of the former, and by the evidences of cystitis.

SUBACUTE OR CHRONIC GENERALIZED MYELITIS OF THE ANTERIOR HORNS.

Instead of having an acute, subacute, or chronic diffused myelitis, you may have an acute, subacute, or chronic inflammation of certain physiological regions of the cord, but let us pass at once to the consideration of another case, which I will have brought to the arena and will study before you. The history of the case is as follows:

Case 2.—M. M., æt. 33, white, widow; occupation, general housework; has had several children, and one spontaneous abortion five months ago. Her husband is dead, but was healthy. Her mother and several sisters died of phthisis; her father of typhoid fever. She had always been healthy until seven months ago, when she contracted chancroids. She was admitted to the Philadelphia Hospital two weeks later, and examination showed chancroids and fistula in ano. At this time her appetite was poor, she had lost some flesh, and was anæmic. While under treatment she was taken with diarrhœa, and was put to bed. About the time the diarrhœa was checked she began to notice burning pains in the palms of the hands and the soles of the feet, with swelling of

[1] Transactions of the College of Physicians of Philadelphia, third series, vol. vi., 1883. Also, Journal of Nervous and Mental Diseases, January, 1883.

Digitized by Google

the parts. She also had burning pains down the anterior surface of the tibia and the posterior portion of the ulna and radius, and girdling pain in the lumbar region. Loss of motion in both upper and lower extremities was soon noticed, but no loss of sensation. The bladder and bowels were not affected. The nails of both fingers and toes presented well-marked white cross-lines. The left side was apparently most affected. Both the hands and feet were cold. Soon a tendency to rotation outwards appeared, and the feet assumed a talipes equinus position.

Until about four months since, she remained about the same, or possibly got a little worse. Since then she has slowly improved, with periods of partial relapse.

Without giving the history further, you will have observed, if you have paid close attention, that the woman was in good general health up to a certain period, when she contracted chancroids. She had not true chancres, and no secondary or tertiary syphilitic symptoms. Bear this point in mind, and do not be misled into making positively a diagnosis of spinal syphilis in this case. While in the hospital she had an attack of diarrhœa, and shortly after partially lost the use of the limbs.

So far as the upper half of the body is concerned, the improvement has been great. The pains have almost entirely disappeared. The transverse lines, as the nails have grown out, no longer are seen.

I will now examine the lower extremities. Looking at the limbs, the first thing which attracts attention is the position which they have assumed. You see the tendency to the equino-varus position—the turning inward and downward of the feet. This is present both in organic and in functional or hysterical disorders. In some recent works on spinal diseases, two pictures are shown side by side; one, of the position of the feet in a form of true myelitis; the other, the position in a hysterical paraplegic. In both, the patient sitting, the feet have assumed this peculiar inward-turning position.

Let us now test the power of motion. She can draw up both legs with the pelvic and some of the thigh muscles, without trouble. Examining the muscles below the knee, I find that, on the left side, she is unable to make dorsal flexion. A scarcely perceptible movement is made, but paralysis of the anterior tibial, peronei, and extensors of the toes is almost complete. She is able, to some extent, to use the gastrocnemius, soleus, and posterior tibial muscles. On the right side, there is only a slight attempt at dorsal flexion, but she can use the posterior group of muscles fairly well.

You observe complete absence of the knee-jerk on both sides, and also of ankle-clonus—but this is very rarely present when the patellar response is absent. A curious fact is that the skin reflexes are sometimes present when the other reflexes are absent. Some plantar reflex is here present.

As far as the general determination of sensation goes, she feels the æsthesiometer in the soles of the feet and elsewhere. The skin seems to retain its sensation. She can discriminate the compass points fairly well. Impressions reach the brain promptly. In this hospital are cases in which from two to fifteen seconds, or even more, are occupied in the transmission of impressions from the periphery to the brain. This is due often not so much to loss of sensation at the periphery, as to morbid obstacles—nodules of sclerosis, for instance—in the highways over which the impressions are carried. In this patient, however, I cannot determine any retardation of the conduction of sensation.

The electrical condition in such a case should always be carefully studied. It is one of the three or four most important diagnostic indications. The tests will be made before you, the farado-contractility first engaging our attention. One electrode is to be applied to an indifferent spot—that is, to one not connected by nervous channels with the muscles which it is desired to test; also to a spot not too near. It may be placed on the sacrum or on the sternum. The second electrode is to be applied to the supplying nerve-trunk, to the motor point, or to the belly of the muscle. I now test the farado-contractility of the tibialis anticus, the extensor digitorum communis longus, the extensor hallucis, and the peroneus longus and peroneus brevis muscles. A movement is produced as the current-strength is increased, but it is not the physiological movement of these muscles. The foot is extended and adducted. This is due to the extra polar diffusion of the current inducing contraction of the posterior group of muscles—the gastrocnemius, soleus, and posterior tibial. Farado-contractility is present in this muscular group, but the muscles under trial give no movement. It is an important practical point to remember that in testing the electrical state of certain muscles, while these may not respond, others close by may contract, and thus mislead the operator.

In determining the reactions to galvanism, a battery of from twenty to sixty cells is required. A few minutes suffice for a general diagnostic determination of this point, but a much longer time is needed for a minute record of the electrical condition. Two electrodes are used. One is the ordinary sponge electrode; the other may be like this in my hand, which is a carbon electrode covered with chamois, and provided with an interrupting handle. The pedal electrode of Dr. Morris J. Lewis, of this city, is a most convenient instrument when you have no assistant. The sponge electrode is to be placed at an indifferent spot, and a general determination of galvano-contractility made. It is almost absent in the same groups which showed entire absence to faradism. Having determined this, the reactions of degeneration are sought. In healthy nerves and muscles a certain definite response is obtained according as the current is closed or opened at cathode or anode with a current of medium strength—*i. e.*, one just capable of causing fair contraction. You get the best contraction with the closure of the cathode. Next, in actual experience with patients, comes anodal closure, although anodal opening is second physiologically. Anodal opening is third; and, finally, we have cathodal opening, which, with a current of ordinary strength, would cause no movement. Any reversal of this order indicates a reaction of degeneration—for instance, if with a current of medium strength the anodal closure contraction is greater than cathodal closure contraction. If the anodal opening contraction is greater than either of the two just mentioned, you have a still more marked reaction of degeneration. If you get that which is obtained only when the muscle is doomed, viz., cathodal opening contraction the most marked, you have a complete reversal of the normal formula. It is not my intention to dilate fully on this topic, but I simply want to say enough to enable you to understand this case. I

Digitized by Google

will test the paralyzed muscles of the leg, applying these principles. No contraction is visible in the anterior muscles below the knee on cathodal closure or opening. The latter, of course, we did not expect. There is slight contraction on anodal opening and closure. Reactions of degeneration are present.

What is the nature of this case? Here are motor paralysis, complete absence of tendon responses, with retention of the skin reflexes; and vaso-motor and trophic changes, as indicated by the color of the skin, change of temperature, and by some wasting; absolute loss of farado-contractility, and marked reactions of degeneration. No anæsthesia is present. This is undoubtedly, in the first place, a case of organic disease. It is, secondly, a spinal affection. The trophic, motor, and reflex disorders, and reaction of degeneration, show that it is an affection of the anterior horns of the cord in large part, if not altogether. It is a case of generalized disease of this region, as both arms and legs have been affected. [This case, since the delivery of the lecture, has made a complete recovery, chiefly under the use of heat and cold to the spine, ergot, mercury, bromides, iodides, and galvanism.]

This disease is not seen often in clinics, but it is of great importance, and not extremely rare. The best name for it is *subacute or chronic generalized myelitis of the anterior horns*. The name gives at once the features of the disease. It is one of the diseases which Duchenne described under the head of *general subacute anterior spinal paralysis*. It is also known as *subacute or chronic anterior polio-myelitis*, and *chronic atrophic spinal paralysis*. It is one of the forms of spinal adult paralysis, but the best names are the first or the last.

I shall take this disease as my standard of comparison in discussing the problems of diagnosis which I have chosen as our topic for these lectures. I do this because of its clear and definite characters, and because, also, it is particularly liable to be confounded with other forms of myelitis and with hysterical paralysis.

Before, however, going on with the discussion, let me read to you the history of another case of the same affection. This was a private patient, a highly intelligent lady, who wrote out for me an account of her case from the beginning. The record is particularly interesting because of the details as to subjective symptoms —details which we are not usually able to obtain in reliable form from the ordinary run of hospital patients.

Case 3.—A young lady, recently married. Her first feeling of sickness came on with fever, severe headache, nausea, and pains in the back and limbs; finally resulting in a steady fever of a typhoidal type. Her only recollections of that time were of terrible sinking spells, and a constant feeling of prostration. She was confined to bed for two months, and one month later went for a week to the seashore. She felt perfectly well while there. It was, however, rainy and damp all the time.

Shortly after her return, she found that the slightest exertion, either in riding or walking, tired her and brought on pain in the left lumbar region extending down the leg to the foot. About five years before this, she had had an attack of "gravel," and since then had been subject, at different times, to pain in the left side and leg.

Two months after convalescing from the fever, and six weeks after returning from the seashore, she was attacked with nausea, severe pain in the stomach, and diarrhœa, which lasted about three weeks. About this time the pain in the loins began, on both sides (although the left side was always the most painful), and was so severe that the only relief she had was when under the influence of hypodermics of morphia. This trouble lasted about four weeks. She also at this time had an excessive irritation of the skin. Although it was in July, and the weather exceedingly hot, she felt cold all the time. It seemed impossible to keep warm. She almost constantly had cold chills, as if some one was pouring ice-water over her. Her limbs also jerked constantly in her sleep. Her feet had a numb feeling.

She was taken with spasms, slight at first, but gradually increasing in strength. They lasted two weeks, and then ceased for a week, when one came on, just after taking a hypodermic to relieve the pain in the small of the back. This was the last spasm she ever had, as well as the most severe. Her nurse said that she was totally unconscious in it, and that her feet were drawn almost to the back of her head, her mouth also being drawn to one side. After that her feet and limbs began to pain her and to be very sensitive to the touch, the pain gradually increasing until the agony became almost indescribable, especially in both great toes, the pain feeling "as if some one was forcing a large pin under the nail, and tearing it from the flesh."

She lost the power of walking, or even standing, and for about six weeks was obliged to lie on her back, as it seemed to increase the pain to lie on either side. Her hands and arms also pained her, although not nearly so much as her feet and legs. She, however, also lost the power of using the hands and arms, and was obliged to wear gloves, as the sheets, and in fact everything that touched her, felt so uncomfortably cold. This cold feeling lasted with her for three months. About the time her feet began hurting her the pain in the small of her back ceased.

About the first of August, a little more than two months after the onset of her attack, she found she could not put her feet to the floor; the blood rushed to them so that they were almost of a purple color. From the first time her feet began troubling her, the pain never for one instant left them. She nearly lost all power in them, and the soreness still continued in her feet, and as far up as her knees. She also suffered great pain in the hips, and at the lower end of the backbone. Her muscles contracted, so that she could not straighten out her feet, which at one time were very much curved.

The pain only began to be noticeably less severe about seven months after her last illness began. And on the first day of February she stood alone, the first time for nearly eight months; and on the tenth day of the same month walked a few steps with the help of a Darrach wheel crutch, although the muscles were still so contracted under her knees as to cause her great pain whenever she attempted to walk. After this she began slowly but surely to improve, and in about six months was entirely well.

For several months, after using much exercise, and also toward evening, the limbs would burn and throb very much, and the only relief found was in having them rubbed.

Digitized by Google

This patient was under my care, in conjunction with other physicians, for several months, until her recovery. Beside the symptoms, as above enumerated by herself, she had lost knee-jerk for both sides, and the reactions of degeneration. Ergot, belladonna, morphia, bichloride of mercury in small dose, iodide of potassium, massage, and Swedish movements, with galvanic electricity, were the agencies chiefly used in her treatment. These measures, with rest, cupping, and the alternate application of ice and hot water to the spine, are chiefly to be depended on in the treatment of myelitis.

HARD CHANCRE OF THE TONSIL.

BY FRANK DONALDSON, JR., B.A., M.D.,
CHIEF OF CLINIC FOR THROAT AND CHEST, UNIVERSITY OF MARYLAND, AND SOMETIME SCHOLAR IN BIOLOGY, JOHNS HOPKINS UNIVERSITY.

THOUGH hard chancre of the tonsil is by no means so infrequent as was formerly supposed, its etiology, symptoms, and appearance are so variable, and its positive diagnosis often so difficult, that the case given below may justify a résumé of the subject as it stands to-day; particularly, as I find in English nothing beyond mere records of cases.

The patient, a prostitute, æt. 29, presented herself at my clinic April, 21st, complaining of sore throat; and gave me the following history: At sixteen she had a sore on her genitals, and was treated, she said, by a physician now dead, for syphilis, who after a time pronounced her cured; at any rate, no constitutional symptoms had at any time developed. She remembered no particulars of her sickness, so many years having elapsed, and could give me no further information beyond the statement of her physician as above.

Having been ill with peritonitis in the University hospital during February, and having suffered constantly with great pain and tenderness over the abdomen since her dismissal in March, she had been unable to ply her vocation, and told me she had had no sexual connection whatsoever since January 28th. In the house to which she returned after her acute illness, there was a man who was suffering from a severe attack of syphilis, with "sore throat and sores in his mouth." Both she herself and the only other woman in the house were fully aware of his condition, having been warned by him not to use his tumbler, knife, etc. Fearful of contracting the disease, my patient had taken pains to avoid using any thing that he might have touched, but had on several occasions, when "skylarking," kissed him in the mouth again and again, and though she would not confess it, resorted, I fear, to disgusting practices. Early in April her throat became sore and uncomfortable on swallowing, and a few days later she noticed a sore on her upper lip. Her throat had gradually become worse until she was led to seek relief.

On examination, the lesion on the upper lip was found to be a superficial erosion with a reddened, densely indurated base discharging a scanty serosanious fluid, and was beyond doubt a hard chancre. The lesion upon the left tonsil, in whose character we are more deeply interested, was a ragged pultaceous ulcer, grayish-white, and not deeply excavated. The tonsil itself was somewhat enlarged; owing to the situation of the ulcer and the natural resistance of the hypertrophied gland the exact degree of induration could not be determined; some glandular enlargement on the left side was present.

There was finally much doubt as to the exact nature of this tonsillar lesion. Was it a primary sore or a secondary manifestation following the sore on the lip? The case was referred to Prof. I. E. Atkinson, of the University, who declared both the sores to be hard chancres. Whether it was also a case of *reinfectio syphilitica* it was impossible to say in the absence of more positive proof of a primary infection of syphilis thirteen years before.

The patient was put upon antisyphilitic treatment and the week following returned with a well-marked roseola and adenopathy, and complained of general malaise, feverishness, loss of appetite, and headache. It was, I think, exactly two weeks later, May 12th, when I saw her again, at which time her hair had begun to fall out and she was suffering considerably with syphilitic arthritis. The tonsil sore had in the mean time healed, leaving a distinct scar, with more or less hypertrophy and hardness of the gland; the labial sore was also much improved.

Under the same treatment the patient has continued to improve, though when last seen there was considerable syphilitic erythema of the palate and both lingual and buccal mucous patches had made their appearance.

Such being the complete history of the case: 1st. The great doubt that the woman had been affected with syphilis in her youth. 2d. The fact that she had been unable to have sexual connection for nearly four months owing to her illness. 3d. The unquestioned exposure and the character of the patient. 4th. The almost simultaneous appearance of the two sores and their physical characters, and finally, the full outbreak of secondary syphilis, would seem to confirm our diagnosis beyond a doubt.

Referring now to the points of interest in this case, the labial chancre needs no comment. The possible reinfectio syphilitica is interesting certainly, but the patient's statement alone as to her first attack is hardly sufficient, and it is unfortunately not now possible to corroborate her statement, the physician who treated her having since died. In view, however, of the interest attached to such reinfection, the following references are given, for in them the subject is thoroughly discussed: Neumann,[1] ———,[2] Arning,[3] Bosetti,[4] Diday,[5] Rollet,[6] Mallet,[7] Sturgis,[8] Vidal.[9]

When we consider the number of cases reported

since 1860, it seems strange that in all French literature there is no case of hard chancre of the tonsil on record previous to this date. As late as 1852 Velpeau declared that this particular lesion seemed impossible, and after him other writers, among them, Vidal de Cassis[1], Martelliere[2] (though the latter admitted the possibility of it), Buzenet,[3] Melchoir Robert,[4] Fournier[5] (in 1856), and Gibert,[6] though they give many hundreds of cases of buccal, make no reference to tonsil chancre.

Fournier (in 1860) was the first to observe and put on record a definite case of chancre of the tonsil, which was one of 77 cases of buccal chancre observed by him. In the following year, Diday[7] reported eight cases and in an elaborate treatise was really the first to give this lesion a definite place in the history of syphilis. Belhomme et Martin,[8] and Rollet[9] described tonsil chancre with cases, while in Desnos,[10] we find a long account of the same and of its complications. Gondouin[11] reports one case; Mauriac[12] and Julien[13] several; the latter describes with great care the initial lesion, its shape, the grayish-white discharge with which it is covered, its regular edges, its slow evolution. We find four cases reported by Hulot;[14] two by Schiragew;[15] four by Boeck;[16] one each by Spillman,[17] A. Hue,[18] Paul Hamonic,[19] Lavallée,[20] Brocq,[21] Merklen,[22] and Thomaschewsky;[23] Taylor[24] reports three from his own practice, one from that of Dr. G. H. Fox, and one from that of Dr. Wigglesworth, of Boston; Knight[25] gives two; Legendre[26] and Pivaudran[27] several of their own observation; and Morell Mackenzie[28] seven.

Such being the history of hard chancres of the tonsil, I shall proceed to give the etiology and physical signs, the functional symptoms and the diagnosis of chancre in this situation. I have not been able to give the exact number of cases reported by each writer, several of the papers referred to being unavailable, and, after all, the exact number is not of particular importance, for it would not enable us to get at the comparative frequency of chancre of the tonsil.

Fournier, however, found one in 471 cases of chancre in different localities, and one in 77 of buccal chancre; while Diday in 671 chancres in various situations found not a single one back of the anterior pillar of the fauces. Morell Mackenzie has seen but seven in his great experience.

Theoretically, tonsil chancre should be more common among women than among men, and Morell Mackenzie's experience confirms this idea, for out of the seven cases seen by him, six were in women. Rollet[1] also found chancre of the mouth more common among women, and Ricord, in five years, saw one mouth chancre in 389 men, and two in 199 women. Diday and Desnos find no reason for thinking mouth and tonsil chancre less common in men, but after a careful examination of the separate cases given above, I think we are quite justified in concluding that chancre of the tonsil is more frequent in women than in men.

It is not necessary to describe the cause and mechanism of mediate or immediate contagion; those interested may consult the works of Diday and Desnos referred to above; suffice it to say that kissing is a fruitful source of contagion, when one or the other person is suffering from a manifestation of mouth syphilis, and disgusting practices also which need not be described.

In young children, chancres of the mouth often arise from taking the milk from the breast of a syphilitic woman, and Wigglesworth[2] tells of a medical student who put his mouth to that of an asphyxiated newly born child and inflated the lungs several times. One month later a hard chancre developed on his right tonsil. Knight,[3] too, tells of a lady who contracted a chancre of the tonsil by using the same tooth powder as her nephew, who was suffering from secondary syphilis. Again, the contagion is carried from one person to another by means of instruments, by knives, forks, glasses, and other household utensils used by more than one person; by nursing bottles (see case by Spillman[4]); by cigar stumps;[5] etc.

But of all the non-venereal causes of chancre of the tonsil, one of the most curious methods of infection is through the tube used by glass-blowers. Rollet, in 1858, was the first to call attention to this mode of contagion, having observed the epidemic at Rive-de-Giers. And later, Guinaud[6] published an elaborate paper describing epidemics at various places and giving the exact method of contagion, viz., the passage of the piece of glass as it was being blown into shape from mouth to mouth, of the glass-blowers. At present each workman has his own mouth-piece.

The objective and subjective symptoms of chancre of the tonsil vary so greatly, and its situation is so remote that it often passes unobserved, and when seen is not diagnosed. In this connection Taylor remarks "that there is little doubt that some cases of the *syphilis d'emblée* or *larvée* of the French were really instances of tonsillar infection." Primary chancre of the tonsil, when situated in the *pharynx*,

is most always found upon one of the tonsils, owing, no doubt, to the structure of these glands, the lacunæ of which are prone to receive and retain the syphilitic virus. Tonsil chancre is usually unilateral, Rizat,[1] however, saw a young woman who had seven chancres in various places, with one on each tonsil, and Rollet also one with a hard chancre on each tonsil.

Tonsil chancre generally begins with slight redness and swelling, without perceptible induration of the gland. In a few days there is pain on deglutition, an increase in the redness and hypertrophy, soon followed by a superficial erosion with increased induration of its base, and more or less, though constant adenopathy on the affected side. A most important sign is the hypertrophy and general tumefaction of the tonsil gland itself, which would seem to be a constant accompaniment of tonsil chancre. This syphilitic hypertrophy of the tonsil will be found minutely described by Hamonic.

The second important sign is the superficial erosion, increasing to an active ulcerating surface, covered usually with a grayish-white coating, thicker or thinner as the case may be. Again the coating is granular, and somewhat irregularly distributed over the surface of the ulcer. Sometimes, however, the erosion at first is very slight and superficial, as in a case by Diday. On the other hand, the lesion may assume the phagedenic form of a deep, sloughing ulcer, with great tumefaction of the neighboring parts. This last form of ulceration would seem to be a rare complication of tonsil chancre, though cases of such extensive ulceration are reported by Brocq, Mauriac, and Rollet.

The third and most important sign of hard chancre here, as elsewhere, viz., induration of its base, is always present, though not always in the same degree, the amount of induration depending on the amount of hypertrophy of the gland before the development of the chancre. The less the chronic hypertrophy, the less the induration, and vice-versa. Induration of the base may, indeed, be the only sign on which to base a diagnosis of primary infection, as in the case reported by Hue.

The next important sign is the well-marked and early submaxillary adenopathy on the affected side. The engorgement is hard and indolent, and may become very great. Resolution would seem to take place in all cases without suppuration, and the submaxillary adenopathy is much more painful than the inguinal engorgement following genital chancres.

Diday thought the duration of tonsil chancre shorter than that of the primary sore in other places.

The functional symptoms of hard chancre of the tonsil are generally slight, and often an outbreak of roseola is the first intimation the patient has of his trouble. See a case reported by Mauriac.

There is generally, however, pain on deglutition. According to Rollet, among chancres of the mouth, those behind the anterior pillar are the most painful. It is in cases of phagedenic ulceration that the pain is greatest, and swallowing becomes impossible, the breath very fetid and the patient extremely prostrated.

[1] Quoted by Legendre, loc. cit.

Cohen[1] says, "Chancre of the tonsil is usually soft." I hesitate to disagree with so high an authority, but after going over a mass of literature on the subject, I am unable to corroborate the statement.

The diversity in appearance and form of chancre upon the tonsil, the absence of functional symptoms, the very situation of the lesion, and oftentimes the denial of the patient, render the diagnosis of this trouble very uncertain. It is to be differentiated from epithelioma; from psoriasis of the mouth; according to Cohen, from the milky patches of smokers and from tuberculous ulcerations; from mucous patches and the perforating, cone-shaped ulcer of tertiary syphilis; from diphtheria (according to Pivaudran); from gangrenous angina of the throat; and from ulcerating gumma of the tonsil gland.

It would seem that a diagnosis between chancre and epithelioma in a case where there is considerable tonsillar hypertrophy, with an ulcer covered by a granular deposit, and where there is a negative history and the patient old, is by no means easy. An interesting case of this kind is given by Merklen.[2] The patient was a man, æt. 64, who had been suffering for two months with a tumor on the left side in the parotid region.

On examination the left tonsil was found to be greatly hypertrophied, hard, and more or less lobulated; there was an extensive granular ulcer, covering nearly the whole surface of the gland; the neighboring parts were infiltrated and hard; there was considerable pain on deglutition and inability to swallow solids; and finally, there was absolutely no history of past or recent syphilitic infection. A diagnosis of cancer was made. Prof. Verneuil, on further examination, pronounced it a case of primary chancre, and shortly after there followed an outbreak of secondary symptoms, which, with the ulcer in the tonsil, rapidly improved under antisyphilitic treatment.

Cases may arise then, where the diagnosis is difficult, and as it is a point neglected by the author[3] in a paper on epithelioma of the tonsil, he is glad to take this opportunity to give the principal signs and symptoms of these two diseases:

SYPHILIS.	CANCER.
Functional Symptoms.	*Functional Symptoms.*
Deglutition and swallowing painful, but rarely impossible, with freedom from pain when the parts are at rest.	Difficulty and pain in swallowing the first and constant symptom, increasing until it is impossible to take food. Lancinating pain referred to the ear.
Physical Signs.[4]	*Physical Signs.*
Some hypertrophy with early superficial ulceration in primary sore. The tertiary ulcer perforating and cone-shaped. Comparatively slight glandular enlargement, not painful, and subsides with the cause of the irritation.	Great hypertrophy, later widespread ulceration. Considerable glandular enlargement and induration, which become very painful, and do not disappear.
Hemorrhage rare.	Hemorrhage frequent.
Slight emaciation.	Great emaciation.
Amenable to treatment.	Not cured by any treatment.

Tonsil chancre may, under some circumstances, be taken for a mucous patch, whose favorite seat would seem to be upon the surface of the tonsil; and this is more likely to happen when the patient is seen for the first time, and secondary symptoms have already manifested themselves, and an ulcer still remains upon the tonsil; or when there is hypertrophy of the tonsil, with an active, and by no means superficial, ulceration of the mucous patch. The mucous patch, however, always follows the roseola; and the patch is, as a rule, superficial and of characteristic appearance, etc. To determine finally between a chancre and a mucous patch upon the tonsil Diday says: "Cauterize the ulcer twice at an interval of five days, and, if it is a secondary ulcer, it will disappear; if a primary, hard chancre, it will not."

Pivaudran thinks that primary chancre may be confounded with diphtheria; but the course of the two diseases is so unlike that such a mistake is hardly likely to occur.

In exceptional cases chancre of the tonsil is complicated by an extensive slough. The presence of a grayish ulcer, surrounded by an œdematous circle, with inflammation of the surrounding parts, points strongly to a gangrenous throat affection, either of a syphilitic origin or a primary gangrenous angina, such as is described by Gubler and Trousseau.

The limitation of the ecchymotic spots, and the absence of its propagation to the pharynx, palate, and larynx, and the general course of the affection, with the appearance or non-appearance of secondary eruption, will settle the diagnosis.

Ulcerating, gummy tumor of the tonsil is distinguished from chancre by a deeper ulceration, and by its dug-out edges. According to Legendre, a good differential sign is the existence of an erythema and peripheral engorgement, which are never found in gummy tumors, but always present in throat chancre. Further, a knowledge of the patient's antecedents will be of great value.

Finally, if the lesion upon the tonsil has been of slow, unilateral development, is superficial, with grayish-white deposit; if there is a history, or even suspicion of syphilitic exposure; if there is glandular enlargement; if the sore on the tonsil appeared from fifteen days to three weeks after exposure, and there is absence of chancre elsewhere; if the patient has not been subject to simple tonsillar angina; if the pain is on the affected side, has lasted for some days or weeks, and has not excited febrile reaction, and the whole is followed in due time by an outbreak of secondary symptoms, certainly we are justified in a diagnosis of chancre of the tonsil.

RECENT RESEARCHES ON THE REDUCING SUBSTANCE OF NORMAL URINE.

BY WILLIAM H. GREENE, M.D.,
OF PHILADELPHIA.

THE question whether normal human urine does or does not contain glucose, has been the subject of extended discussion and numerous elaborate investigations, but the results have for the most part intensified the obscurity with which the problem has been surrounded. Careful and trustworthy observers have ably advocated the opinion that small proportions of glucose are constantly present in the urine, and have based their conclusions on the indications afforded by the dextrogyrate property of urinous extracts, by the slight reducing action exercised by nearly all specimens of urine on Fehling's and similar solutions, and by the fermentation under the influence of yeast. All efforts to isolate the glucose in substance have failed, notwithstanding enormous quantities of urine have been subjected to the necessary operations, and it is difficult to understand how appreciable proportions—the normal excretion has been placed as high as one, and even two grammes per day—could disappear during the attempts at extraction.

Experimenters who have not accepted as conclusive, the results furnished by the ordinary tests, have therefore sought, in the presence of an unknown substance, an explanation of reactions so closely simulating those of glucose. With regard to these tests, it may be said that of the substances possibly or probably existing in the urine, glucose is by no means the only one which would rotate the plane of polarized light and which possesses reducing properties; greater weight would attach to the fermentation test, but in addition to the fact that this method has yielded results indicating an exceedingly minute proportion of glucose, it must be considered that the yeast-cells alone are capable of producing a certain quantity of carbonic acid gas, and that this gas is disengaged in small quantity by urine to which no yeast has been added. If, then, it can be shown that normal urine contains constantly another substance which will reduce cupro-alkaline solutions, and which is dextrogyrate, there can remain no ground for assuming the presence of glucose.

In 1875, Von Mering and Musculus[1] found that the ingestion of chloral hydrate was followed by the appearance in the urine of a still then unknown levogyrate acid; this compound, which was named urochloralic acid, was made the subject of elaborate investigation by Külz,[2] in 1881, and again in the subsequent year by Von Mering,[3] who found also that butylchloral hydrate is eliminated in the urine as urobutylchloralic acid. In the meantime Jaffé[4] had in 1878 discovered that orthonitrotoluol is converted in the organism not only into orthonitrobenzoic acid, which would be the oxidation product naturally expected, but principally into an optically active acid that decomposed readily into urea and a new acid which he called uronitrotoluic. The latter can without difficuly be dehydrated by boiling with dilute sulphuric acid; it then loses a molecule of water, and is converted into orthonitrobenzyl alcohol and an acid which Jaffé was unable to isolate. He, however, attributed to it the composition $C_1H_{10}O_7$, and considered that it formed with the orthonitrobenzyl radical a conjugate compound resembling a glucoside. Although he could not verify by analysis the composition of this quasihypothetical

Digitized by Google

acid, he did not hesitate to consider it as the common basis of a group of compounds, including his uronitrotoluic acid, the urochloralic acid of Von Mering and Musculus, the urobutylchloralic acid of Von Mering, and an optically active substance obtained in large quantity by Wiedemann[1] from the urine voided after the administration of camphor. All of these substances are levogyrate; all are capable of reducing cupro-alkaline solutions by the aid of heat, and all are decomposed after the manner of glucosides by boiling with dilute sulphuric acid.

The hypothetical acid of Jaffé was isolated, studied, and analyzed in 1880, by Von Schmiedeberg and Meyer, who found that it possessed indeed the composition indicated by Jaffé, and that camphor is eliminated in the urine as one of its conjugate compounds which can be decomposed by hydration, yielding campherol, and the new acid which they named glycuronic.

The chemical relations between these conjugate compounds, that form part of a numerous class found in the system under similar conditions, and the products of their decomposition by hydration when heated with dilute sulphuric acid, are expressed in the following equations:

$$\underset{\text{Urochloralic acid.}}{C_8H_{11}Cl_3O_7} + H_2O = \underset{\text{Trichlorethyl alcohol.}}{C_2H_3ClO} + \underset{\text{Glycuronic acid.}}{C_6H_{10}O_7}.$$

$$\underset{\text{Urobutylchloralic acid.}}{C_{10}H_{15}Cl_3O_7} + H_2O = \underset{\text{Trichlorobutyl alcohol.}}{C_4H_7Cl_3O} + C_6H_{10}O_7.$$

$$\underset{\text{Uronitrotoluic acid.}}{C_{13}H_{15}NO_9} + H_2O = \underset{\text{Nitrobenzyl alcohol.}}{C_7H_7NO_3} + C_6H_{10}O_7.$$

$$\underset{\text{Camphoglyceronic acid.}}{C_{16}H_{24}O_8} + H_2O = \underset{\text{Campherol.}}{C_{10}H_{16}O_2} + C_6H_{10}O_7.$$

Glycuronic acid reduces Fehling's solution by the aid of heat, and is optically active, but while its conjugate compounds are levogyrate, the free acid is dextrogyrate. Its composition, its properties, and its double function of acid and aldehyde, indicate as exceedingly probable that glycuronic acid is derived directly from glucose. The polarmetric estimation of glucose in diabetic urine frequently reveals a greater dextro-rotation than should be produced by the quantity of glucose present as estimated by cupro-alkaline reduction; at other times a levogyrate action is observed after the glucose has been destroyed by fermentation. These variations would at once become explicable if it could be shown that in the one case the urine contains free glycuronic acid, and in the other a compound of that substance. On the other hand, the existence of notable proportions of glycuronic derivatives in the urine of diabetes mellitus would appear to point clearly to a relation between glycuronic acid and glucose.

Since compounds of such diverse nature as chloroform, chloral, camphor, toluol derivatives, and many others, are eliminated by the urine in conjunction with a common associate, the idea appears at least plausible that this common factor is a constituent of normal urine, and a constant product of normal tissue waste. If this view be correct, then is the reduction of Fehling's solution by normal urine readily understood.

M. Flückiger[1] has reviewed this whole subject with great care, and has recently published the results of a long series of experiments which appear to indicate a great probability that glycuronic acid, or one of its compounds, does exist in normal urine. After finding, in accordance with the statements of other observers, that the reducing power of the urine is equivalent to that of a 0.15 to 0.25 per cent. glucose solution, he has shown that in about one-third of the specimens examined this power was increased by boiling with dilute sulphuric acid, while in the others such treatment produced no changes. By evaporation of the urine to one-tenth of its volume, and dilution of the residue with sufficient water to make up the original volume, five-sixths of the reducing substance is destroyed, or so altered as to lose its reducing powers, when the evaporation is conducted over an open fire or at a temperature of 212° F., and about one-sixth when it is conducted at a temperature of 140°. The reducing substance may be extracted by alcohol from the syrupy residue of concentrated urine, but unfortunately when the alcoholic solution is evaporated and the residue dissolved in water, the reducing power of the solution so obtained cannot be measured, for the reduced cuprous oxide remains in solution. Happier results followed the trial of dialysis; forty-eight hours dialysis of urine reduced to one-fourth its volume, gave an aqueous solution whose reducing power was equal to that of the unaltered urine.

The obtainment in substances of such an unstable compound as glycuronic acid from so dilute a solution as that in which it would exist in the urine, if it exist there, is hardly to be thought of. Flückiger therefore bases his conclusions on the similarities between the reactions of the reducing constituent of urine and those of glycuronic acid. His experiments show that the urine constituent is almost entirely destroyed by evaporation above 194° F., and experiences a partial destruction at 140°; that it is soluble in alcohol but insoluble in ether; that only a small portion of it can be precipitated by barium hydroxide, but that it is precipitable by lead acetate, particularly by the basic acetate; although the greater portion of it is decomposed either by the reaction of the lead solution or by the subsequent treatment of the precipitate; that it is able not only to reduce cupro-alkaline solutions, but to retain in solution the resulting cuprous oxide; that it is dialyzable, and that it yields acetone when oxidized by a mixture of potassium dichromate and sulphuric acid.

The reducing substance of normal urine acts much more slowly on cupric solutions than does glucose; the compounds of glycuronic acid also require a longer interval to effect the reduction. So

[1] Wiedemann, Archiv für experiment. Pathologie, vi. 630.

[1] Flückiger, Zeitschr. physiolog. Chemie, ix. 324.

Digitized by Google

far as is known, the property of retaining in solution the cuprous oxide reduced from cupric solutions is possessed only by nitrogenized compounds, and this fact would seem to contradict the proposition that the reduction is due to a glycuronic compound; but glycuronic acid is especially apt to form conjugate combinations with such nitrogenized substances as would prevent the precipitation, and it is not improbable that one or more of these combinations may exist in the urine. By the oxidation of glycuronic acid Schmiedeberg and Meyer obtained only formic and carbonic acids, but Flückiger finds that a small quantity of acetone, or at least a volatile liquid responding to the reactions of acetone, is formed at the same time.

As the conclusions to be drawn from these researches, Flückiger proposes the hypothesis "that the reducing substance of normal urine is a conjugate compound of glycuronic acid, which is derived from the glucose of blood, and to the decomposition of which is to be attributed the acetone found in physiological and pathological urine."

He thinks also that the oxybutyric acid recently extracted by Minkowski[1] and Külz[2] from diabetic urine may find its source in glycuronic acid, one molecule of which would yield carbon dioxide, and formic, and oxybutyric acids. He has indeed found that by long boiling with water glycuronic acid yields an acid which is not volatile with vapor of water, but which he has not yet obtained in quantity sufficient for analysis. That acetone may be extracted from diabetic urine was shown by Kaulich[3] in 1860, and in 1870 Lieben[4] found that normal urine contains a substance which responds to the iodine test for acetone; that this substance is actually acetone was clearly demonstrated by Von Jaksch,[5] who in 1883 conducted a series of investigations which resulted in the extraction of acetone in sufficient quantity for identification by its boiling point and by analysis of its compound with sodium acid sulphite. Minkowski has attributed this acetone to the oxidation of his oxybutyric acid; if Flückiger's theory be correct, the oxybutyric acid itself is derived from a glycuronic compound. It is worthy of note that Flückiger has obtained as much as two cubic centimetres of acetone by the oxidation of the residue of thirteen litres of normal urine which were evaporated at a low temperature and from which the urea had been removed.[6]

While the results of this investigation here summarized are not sufficiently positive to exclude the possibility of error, and the conclusions are not, therefore, unquestionable, the laboratory work involved is surrounded by difficulties of no small moment, and though the solution of the problem may not be final, the direction of further research seems clearly indicated.

A CASE OF SIMPLE ENDOCARDITIS LIMITED TO THE RIGHT HEART.

Reported by RADCLIFFE CHESTON, M.D.,
RESIDENT PHYSICIAN, EPISCOPAL HOSPITAL

By permission of Dr. F. P. Henry, the physician in charge, I report the following case of simple endocarditis limited to the right heart, occurring in the wards of the Episcopal Hospital, as interesting, owing to the rarity of its primary occurrence during adult life:

Eliza H., æt. 60, single, born in England, was admitted to the ward on March 27, 1885, with left-sided hemiplegia, from which she had been suffering for five weeks. The attack came on suddenly during the night. She was awakened by the pain and intense itching in left arm and leg, and on attempting to move she fell out of bed, and was picked up completely paralyzed on left side. The muscles of the face were paralyzed on the right side, and she had no control over bladder or rectum. Her family history was good; she had never had rheumatism or syphilis. As far as I could ascertain, she had always been a healthy woman up to the time of her present trouble, excepting slight paroxysms of præcordial pain, for a month before the present attack.

On admission, she was found to be very much emaciated; had complete paralysis of left side; no anæsthesia; left arm and leg slightly œdematous. Intelligence very good; sight good; pupils small, equal, and responsive; could not sleep; no control over bladder or rectum. Heart was feeble and accelerated, with a soft, systolic murmur, heard best at ensiform cartilage. She gained control over the bladder and rectum, for a short time, under treatment with the syrup of the hypophosphites, strychnia, etc., but gradually lost ground, and died with a feeble, rapid heart and great dyspnœa, on the 7th of May.

Autopsy.—Brain very soft; vessels full; those at base of brain very hard and patulous, showing atheroma of their walls. The dura mater was inflamed and adherent to the brain, with patches of lymph along the longitudinal fissure; the other coverings of the brain were also inflamed. In the cortical substance of the third ascending frontal convolution, close to the longitudinal fissure, was found a clot the size of an English walnut, undergoing softening. There was very little effusion into the ventricles. The heart was found to be about the normal size, covered with fat, and its walls of natural thickness. The aorta was dilated and decidedly atheromatous. The coronary arteries were enlarged, showing also atheromatous change. The left heart showed no pathological change, both the aortic and mitral valves were perfectly competent by the hydrostatic test, and of normal texture, as were also the pulmonary valves; but the tricuspid valve was found to be incompetent; the two posterior cusps were bound down to the walls of the heart by a fibrinous exudation, with a small fibrinous clot between one of the cusps and the heart-wall. Along the margins, on the auricular surface of the cusps, were minute rose-colored vegetations, while the cusps themselves were considerably thickened back to their base. In the right auricle, on the

Digitized by Google

right posterior wall, was found a fibrinous clot, one inch and a half long, one inch wide, and a third of an inch thick, firmly bound to the wall of the auricle so tightly that when it was detached almost the whole muscular and serous layers came with it.

Unfortunately, the other organs were not examined, as the heart was taken out in reference to the brain lesion, and was not examined until the body was closed up.

In conclusion, I would like to draw attention to a few special points of interest, viz.:

1st. The limitation of the endocarditis to the right heart after fœtal life, an extremely rare occurrence.

2d. To the binding down of the cusps of the valve to the heart wall, which is mentioned in Dr. Byron Bramwell's work on *Diseases of the Heart*, as very exceptional in simple endocarditis.

3d. To the fibrinous clot, bound so firmly to the wall of the right auricle.

MEDICAL PROGRESS.

THE TREATMENT OF HERPES OF THE CORNEA.—M. GALEZOWSKI (*Recueil d'Ophthalmologie*, March, 1885) considers febrile herpes of the cornea to be a disease of frequent occurrence in cold and moist seasons. It is characterized by intense photophobia, lacrymation, and perikeratic redness. The margin of the cornea presents fine ulcerations, as though portions of the membrane had been eroded with the point of a pin. As a rule, they do not penetrate deeper than the layer of Bowman, and they are arranged in a radial manner from the centre towards the circumference along one or more radii. A remarkable feature of the disease is that the cornea is perfectly insensitive. Throughout the whole extent of the herpetic eruption the cornea may be rubbed or pressed with a probe or needle without the least pain being experienced. The other parts of the cornea, however, preserve their normal sensibility. The total anæsthesia of the cornea in the affected portion distinguishes the disease from phlyctenulæ of the cornea, and from abscess of this membrane. The treatment of the disease consists in the employment of the compressive bandage, especially combined with moist heat in the form of spray and boric acid. This acid, he believes, destroys the microbes which accumulate in corneal ulcers and facilitates the process of cicatrization by acting as an astringent. He prescribes it in three forms. (1) In a 2 per cent. solution, either as a lotion, or a douche, or a spray. (2) In the form of an ointment containing one grain of the acid to forty of vaseline, introduced between the lids two or three times daily. (3) In the form of a fine powder, which should be applied to the surface of the cornea with a camel-hair brush. He exchanges the boric acid for atropine or pilocarpine once or twice a day. Internally quinine may be administered with advantage.—*The Practitioner*, July, 1885.

THE RESULTS OF THE USE OF ANTIPYRINE AT THE BOSTON CITY HOSPITAL.—DR. GEORGE B. SHATTUCK in *The Boston Medical and Surgical Journal*, of July 23, 1885, recounting the results of the use of antipyrine at the Boston City Hospital, says: Antipyrine was administered in several cases of intermittent, without interrupting the chills and without appreciable effect. This failure was anticipated from our previous experiences with kairine. A few instances are reported from Germany, in which the periodicity of the attacks was broken temporarily by large doses; but such instances are exceptional, and no antiperiodic action has been claimed or can be allowed. All these coal-tar derivatives resemble quinine in their antipyretic action, but differ from it in lacking the specific antiperiodic action upon malarial conditions.

The fall in temperature ordinarily begins to declare itself in about an hour after giving antipyrine, reaching its maximum in from three to five hours after the full dose of six grammes, divided in the German fashion, continuing on an average about eight hours, though sometimes lasting twice as long. A fall of from 3° to 5° F. is very easily secured. The change in the pulse is by no means always proportioned to that in the temperature. The urine is somewhat diminished, free from albumen, and but little altered in color—in the last respect offering a contrast to urine after kairine.

We have had no experience with antipyrine in children. Two German observers who used it largely in a children's clinic report that it is well borne by them, and suggest one decigramme for each year of age as a a rule for the dose to be given.

As a general result of our experience at the City Hospital, where further trials are still being made, I am able to endorse antipyrine as: (*a*) An efficient and reasonably safe antipyretic, without antiperiodic qualities.

(*b*) Whose exhibition in proper doses is, as a rule, unattended by serious discomforts or drawbacks.

(*c*) By reducing a high temperature it frequently substitutes calm for excitement, and sleep for restlessness.

(*d*) Otherwise it does not usually modify the course of disease, and certainly not of typhoid fever.

(*e*) The quality of the sample used must be carefully watched in these synthetical compounds. A poor article will produce vomiting, chills, and collapse, when a good one will not; or, on the other hand, may be inefficient when the pure drug would have proved effective.

Antipyrine may be employed in a variety of febrile conditions, though its desirability in phthisis is questioned; but typhoid fever is the disease in which it is likely to be most largely and frequently used. When used in typhoid it should be distinctly without expectation of modifying the course of the disease. To emphasize our own experience on this point, I may quote that of Alexander, who reports a severe relapse in typhoid after the administration of fifty-four grammes of antipyrine in divided doses throughout the first attack; and of Dr. William H. Draper, in whose service at the New York Hospital, of five patients *dying* from typhoid fever, one took ten grammes in ten doses during five days; a second twenty-seven grammes in seven doses during six days; a third thirty-four grammes in twenty-one doses during eight days; a fourth forty-eight grammes in ten doses during seven days; a fifth three hundred and twenty-one grammes in sixty-five doses during thirty days.

THE NUTRITION OF THE NERVOUS SYSTEM.—DR. MAIRET, at the close of a critical article upon the nutrition of the nervous system, says the relations which

Digitized by Google

exist between phosphoric acid and the nervous system are:

1. Phosphoric acid is intimately related with the nutrition and functional power of the brain. The brain in action takes up phosphoric acid in combination with the alkalies, and forms phosphoric acid in composition with the earths.

2. Intellectual exertion reacts upon general nutrition and modifies it.

3. Intellectual exertion modifies the elimination of phosphoric acid by the urine, and diminishes the percentage of phosphoric acid in composition with the alkalies and increases the percentage in combination with the earths.—*Archives de Neurologie*, July, 1885.

EXPERIMENTS UPON ENGRAFTED BONE.—DR. AMBROGIO FERRARI, after a long series of experiments upon the phenomena attending the engrafting of bone, reaches the following conclusions:

1. Pieces of bone engrafted into the shaft of a long bone become completely united and continue to live.

2. They not only continue to live, but also grow.

3. That such results follow without reference to the position in which the engrafted bone is placed.

4. The reunion of grafts occurs by a true vascularization which takes place between the engrafted bone and that into which it is introduced.

5. That a bony callus, periosteum, and medulla are formed in relation with the engrafted bone.

6. That, as in fracture, this callus possesses a temporary vitality.

7. That after a certain time the callus, periosteum, and medulla are absorbed, and the engrafted bone is nourished only by a greater vascularization.

8. That grafting occurs more completely if the inserted bone is in exact adaptation with the margins of the bone receiving it. While this observation is not verified, in a case where the opposite condition existed, a longer time was necessary for union to take place.

9. The most complete and careful antisepsis is required in order that complete union of the engrafted bone may occur.

10. The engrafting of several pieces of bone succeeds completely.

11. That in case of engrafting of several pieces of bone with partial suppuration, union of some of the pieces may take place provided suppuration does not extend to that portion of the engrafted bone in communication with the medulla.

12. Besides antiseptic precautions compression is required to maintain contact between the medulla and the pieces of bone engrafted in order to obtain a successful result.—*Gazzetta degli Ospitali*, July 22, 1885.

PSEUDO-SYPHILITIC PARALYSIS.—M. FERDINAND DREYFOUS distinguishes the following clinical forms of pseudo-syphilitic paralysis.

1. Cases in which syphilitic infection is known to exist and in which paralysis appears with slight syphilitic manifestation. The lesion in these instances can scarcely be mistaken, and even when osseous manifestations are ignored the relation between syphilis and the paralysis may be suspected. Thus Bednar and Henoch saw what they considered syphilitic paralysis in children, and referred them to the diathesis. Paralysis here appears as a manifestation of syphilis —*i. e.*, as a specific paralysis.

2. Cases in which the disease seems to have a traumatic origin. Fracture, displacement, or subluxation being only seen, the rôle of syphilis in the production of the disease may be overlooked. In such cases the paralysis appears as the result of traumatism, and, therefore, as a surgical affection.

3. Cases in which syphilis is ignored, no sign of the disease being manifested, and no other lesion being discoverable in any organ save the paralyzed member.

Accordingly, only infantile paralysis is suspected. In such cases the disease is presented as a simple paralytic affection, and its syphilitic origin must be traced.—*Revue de Médecine*, July, 1885.

OBLITERATION OF ONE LUNG AND DISPLACEMENT OF THE HEART.—At the closing meeting of the Islington Medical Society, on the 26th ult., DR. GLOVER gave the particulars and showed the specimens of two very striking lesions in the case of a man, aged sixty-three, whom he had known for several years as a dispensary patient and otherwise. The most noticeable peculiarity was the complete displacement of the heart. It occupied the right side, and beat between the fourth and fifth ribs. This fact had been observed thirty-five years ago by Mr. Jackson, one of the oldest members of the Society, and the patient had been examined by many physicians, amongst others by Dr. Austin Flint, who came to the conclusion that there was no transposition of organs—a conclusion verified by the post-mortem. But the autopsy revealed another lesion, which was as remarkable as the malposition of the heart. This was the almost complete absence of the right lung. It had to be long sought for ere it could be found, and was then discovered as a very hard shrivelled substance, in shape something like a sausage. On being cut into, it was found to consist almost entirely of thickened pleura, the pleura being at points half an inch thick. The lung substance was nearly destroyed, not with intersecting bands of fibrous tissue, but by this envelope of thick pleura. The left lung was correspondingly large. No history of pleurisy could be traced in the patient's life, and no history of consumption in that of his family. He had always been weak and slight. His mother always had noticed "a beating on the wrong side." He used to have severe bleedings at the nose. His chief troubles had been cough and rheumatism. He died in the Islington Workhouse of broncho-pneumonia. It is common to say that a person has lost a lung, but here the statement was a literal expression of the fact, though the patient contrived to live without it, and with his heart on the wrong side, for sixty-three years.—*Practitioner*, July, 1885.

THE INCOMPATIBILITY OF CHLORAL HYDRATE IN THE PRESENCE OF POTASSIUM BROMIDE AND ALCOHOL.—PROF. GEORGE F. H. MARKOE, in experimenting with solutions of chloral hydrate finds this drug incompatible with bromide of potash and alcohol. He says: Experiments prove that the alcohol is the cause of the trouble, and the writer thinks that the chloral hydrate is changed into the less soluble chloral alcoholate.

The writer found that the addition of potassium bromide, sodium bromide, sodium chloride, and magne-

Digitized by Google

sium sulphate to strong solutions of chloral hydrate, together with the presence of alcohol, determined a separation of the liquids into two layers. Ammonium chloride, ammonium bromide, potassium nitrate, and calcium bromide did not disturb the same chloral solutions.

The practical lesson to be learned from this incompatible prescription is that alcoholic preparations should not be prescribed with chloral hydrate, especially not in connection with the bromides of potassium and sodium, because if concentrated solutions are used the chloral will separate as alcoholate, float on the surface, and a great risk will be incurred of giving a large overdose, the patient having received no caution with regard to the necessity of shaking the contents of the bottle before taking a dose.—*Boston Medical and Surgical Journal*, July 23, 1885.

APHASIA AND ITS DIVERSE FORMS.—M. BERNARD, in a thesis upon aphasia and its diverse forms, recognizes the special features of the affection under the following heads:

1. Aphasia is the amnesia of signs.

2. The complex and varied conditions embraced under the term aphasia have been observed long since. Up to the investigations of Bouillaud, no synthetic study of the affection had been made. Broca first analyzed and definitely fixed the symptoms and anatomical localization of one of the forms of aphasia, *i. e.*, of aphemia, or abolition of the power of articulate speech.

3. By rigorous application of the anatomo-clinical methods, Charcot established also the existence and independence of other forms of aphasia-agraphia hitherto contested, verbal deafness, verbal blindness—forms distinguished by Marcé, Wernicke, and Kussmaul.

4. Words, as are the generality of signs, are not units, but composites of at least four elements. They must be *heard* and *articulated*, *read*, and *fixed by writing*. Aphasia may depend on one or more of these elements, whence are derived the four principal forms of aphasia.

5. Blindness of words is amnesia of the signs and figures of written speech in particular. The patient sees the signs, but cannot interpret them. The left inferior parietal lobule of the brain is constantly involved in the case of verbal blindness. Hemiopia to the present time has always accompanied it.

6. Verbal deafness is the inability to comprehend a spoken word, or, indeed, all language heard. It depends upon a lesion of the first left temporo-sphenoidal convolution.

7. Aphemia, or loss of memory of the coördinated movements necessary for the articulation of speech, depends upon a lesion at the base of the third left frontal convolution, and is frequently accompanied by right-sided hemiplegia.

8. Agraphia is the abolition of the coördinated movements necessary for writing. Its anatomical location is probably the bottom of the second left frontal convolution.

9. In the left-handed the right hemisphere is the seat of the lesions upon which aphasia depends.

10. All representation of ideas and all speech may be affected.

11. The independence and relevancy of each variety of aphasia cannot be estimated in those cases in which they coexist in the same patient, inasmuch as in such conditions the different forms of expression are very unequally affected.

12. Symptoms of aphasia are extremely variable from time to time, even in the same patient, a fact which imposes upon the physician, and especially upon the legal physician, the necessity of frequent examination.

13. No formula can be given as to either the moral capacity or the intellectual strength of the aphasic.

14. Whatever may be the form, the progress, and the cause of aphasia, prognosis must always be made with much reservation.—*Revue Médicale*, June 6, 1885.

TREATMENT OF TUBERCULOSIS.—POTAIN recommends the annexed prescription as a remedy in tuberculosis:

℞.—Sodii chloridi . . . . ℥ijss.
Sodii bromidi . . . . gr. lxxv.
Potassii iodidi . . . . gr. xv.
Aquæ dest. . . . . f℥iij.—M.

S.—Dessertspoonful every morning in a cup of milk.—*Revue de Thérapeutique*, July 15, 1885.

OINTMENT FOR THE TREATMENT OF ITCH.—KAPOSI recommends the following ointment in the treatment of itch.

℞.—Naphthol . . . . . ℥iv.
Saponis vird. . . . . ℥iss.
Cretæ præcip. . . . . ℥iiss.
Adipis . . . . . ℥iij.—M.

Apply thoroughly with friction to the regions affected and powder with starch. The ointment has no disagreeable odor and does not stain the garments. It, however, causes cutaneous inflammation under the form of red spots, urticaria or disseminated papules of eczema, which are not severe. For nursing and young children the naphthol should be diminished to the proportion of 5 to 100.—*L'Union Médicale*, July 25, 1885.

SEA BATHS AS A CAUSE OF EAR DISEASE.—F. BOBONE, in a research into the causation of ear disease by sea baths, gives the following résumé of his conclusions:

1. Sea baths are sometimes the cause of serious disease of the ear.

2. The disease is usually occasioned by the entrance of water into the external auditory meatus, and is found in those persons who dive or plunge under water.

3. Among the affections so caused, external otitis and tympanitis predominate.

4. Purulent otitis of the middle ear is also frequently met with as a result of sea baths, but frequently is secondary to the tympanitis.

5. Purulent otitis of the middle ear as a result of entrance of water into the tympanum through the Eustachian tubes, is of extreme rarity.

6. Diving and plunging under water is useless and dangerous and the practice should be deprecated to bathers, especially to those whose ears are already diseased.

Digitized by Google

7. Syringing the external auditory canal with sea water, a procedure still recommended by some practitioners is irrational and far more productive of evil than of good.

8. A pledget of cotton in either ear previous to entering the water will prevent much of the danger to hearing resulting from the entrance of sea water into the auditory apparatus.—*Gazzetta degli Ospitali*, July 19, 1885.

NEUROSES OF THE STOMACH.—DR. OSER, in the *Wiener Medizinische Blätter*, divides neuroses of the stomach into two classes.

1. Those dependent on a diminution of the power of motion.

2. Those which are dependent on an increase of this power.

He notes in the first group:

1. Rumination, which results probably from a paralysis of the cardia. Light forms may be cured by nutriment without fluids, dorsal decubitus after meals, or by faradization of the cardia. Grave forms terminate fatally.

2. Insufficiency of the pylorus. In this condition he advises the distention of the stomach by carbonic gas.

3. Gastroplegia, or insufficient muscular action of the stomach.

In the second group he places.

1. Cramp of the cardia, which may be diagnosticated by the œsophageal sound.

2. Cramp of the pylorus, which is due to a reflex caused by pressure.

3. General gastric cramp.

4. Peristaltic derangements, frequent in hysteria and neurasthenia.

5. Nervous vomiting.—*L'Abeille Médicale*, July 6, 1885.

THE PHYSIOLOGICAL ACTION OF CHINOLINE TARTRATE.—DR. CONRAD BERENS, in *The Therapeutic Gazette*, of July 15, 1885, in an exhaustive experimental study of the physiological action of chinoline tartrate, reaches the following conclusions:

1. Chinoline tartrate is a powerful agent, producing death by asphyxia.

2. The drug increases the force and frequency of the respirations by stimulating the vagus roots in the lung.

3. It paralyzes respiration finally by a secondary depressant action upon the respiratory centre.

4. It does not cause convulsions.

5. It lessens, and finally abolishes, reflex action by a direct action upon the cord, and by a slight action upon the muscles and nerves.

6. It diminishes or abolishes muscular contractility respectively when applied through the circulation or directly.

7. It coagulates myosin and albumen.

8. It causes insalivation by paralysis of the secretory fibres of the chorda tympani; increases the flow of bile; has no action upon the spleen.

9. It lowers blood-pressure by paralyzing the vasomotor centres, and by a direct depressant action upon the heart-muscle.

10. It diminishes the pulse-rate by direct action upon the heart.

11. It lowers the temperature by increasing the loss of heat.

12. It is a powerful antiseptic; and, finally,

13. Its paths of elimination are not known.

OINTMENT IN ULCER OF THE CORNEA.—GALEZOWSKI recommends an ointment as follows in the treatment of ulcerated cornea:

℞.—Iodoformi pulverati . gr. xv–xxx
Vaselini puri, . . ʒiiss.—Mix carefully.

The ointment is useful in herpetic and scrofulous ulcers of the cornea. It acts also favorably in ulcers appearing in syphilitic subjects. It may be used several times during the day. In addition, a collyrium of pilocarpin and douches of carbolized spray are also beneficial, used fifteen or twenty days. The ulcer is filled up by new tissue, and cicatrization gradually progresses.—*L'Union Médicale*, July 9, 1885.

SYPHILITIC AFFECTIONS OF THE LARYNX; THEIR FORM AND FREQUENCY.—G. LEWIN, in *Archivi di Laringologie*, Napoli, 1885, enumerates the syphilitic lesions of the larynx as follows:

1. *Erythema*, characterized by a tendency to superficial exfoliation. Catarrh of the larynx exists only in cases complicated by other diseases.

2. *Mucous patches* (little marked, however) are observed upon the vocal cords, in those parts supplied with papillæ. Their ulceration cannot be affirmed with certainty.

3. *Perichondritis*, not always a result of transmission from the tissues overlying the cartilages, inasmuch as the perichondrium may be primarily affected.

4. *Œdema of the larynx*, in general secondary in syphilitics, and is due to other morbid causes than are associated with specific laryngitis.

5. *Laryngeal syphilis* is relatively rare when syphilis is subjected to rational treatment.

The prognosis of all affections of the larynx, except cicatricial stenosis, is very favorable when treated by subcutaneous injections according to the method originated by the author.—*Lo Sperimentale*, June, 1885.

THE EMPLOYMENT OF WOOD CHARPIE AND WADDING IN THE DRESSING OF WOUNDS, AND AN ANTISEPTIC POWDER REPLACING IODOFORM.—At a recent meeting of the Paris Surgical Society, M. CHAMPIONNIÈRE criticised the antiseptic gauze generally employed in the Listerian dressing of wounds, as being almost impermeable to fluids, and as retaining its antiseptic qualities for a limited time only. He also held that it is poorly prepared, and irritates the skin.

M. Championnière further announced that for four months he had used in nearly all his more important operations a new substance, invented in Germany—*wood lint*. This is a preparation of the wood of the fir tree, resembling a paste of paper, and impregnated with a solution of corrosive sublimate of 1 to 4000 in strength. When combined with wadding in a proportion of one-fifth, it receives the name of wood wadding.

The substance is soft to the touch, easily compressed, and capable of readily absorbing large quantities of fluid, so that when placed in contact with a wound, the discharges therefrom do not appear or escape from the dressing.

Digitized by Google

The amount of corrosive sublimate contained in the dressing is relatively large, and when infiltrated into the discharges of the wound readily prevents putrefaction. Owing to these qualities, it is possible to allow a dressing to remain a much longer time than ordinarily is possible, without removing it.

M. Championnière further remarked that the dressing under consideration sometimes fissures, and that thus, if employed alone, septic infection may thereby result. To obviate this, the wound is directly sprinkled with the following powder: Iodoform, sifted; powdered Peruvian bark; powdered benzoin; and powder of magnesia, saturated with some eucalyptus. This preparation is superior to simple iodoform, both on account of its lack of disagreeable odor and greater cheapness.—*L'Union Médicale*, July 7, 1885.

TREATMENT OF ANÆMIC NEURASTHENIA.—MAXIMOWITCH recommends the following for the treatment of neurasthenia due to anæmia:

℞.—Ferri bromidi,
Quiniæ hydrobrom. . . . āā 3j.
Ext. rhei . . . . . q. s.—M.
S.—Ft. pil. cxx.

Dose: Two pills three times daily.—*Revue de Thérapeutique*, July 15, 1885.

THE DIAGNOSIS OF APPARENT DEATH.—M. BUSH, in the *Centralbl. f. Nervenheilkunde*, 1884, suggests the application of the faradic current to different parts of the body, in order to excite contraction of the muscles. If the attempt is successful, a surface thermometer, or an ordinary thermometer with proper precautions, is placed and retained upon the skin for from three to five minutes, while contraction of the subjacent muscles is maintained. If the temperature rises, the person is alive.

A second method suggested is the following: In normal conditions, violent mechanical excitation, as pinching of the skin, determines a rise of temperature in an extensive circuit by vascular reflex dilatation, and the same phenomenon is observed after application of snow or ice. Nothing similar occurs in a corpse. The author has not, however, had opportunity to test the correctness of his theory upon any case of apparent death.—*Archives de Neurologie*, July, 1885.

CONTRIBUTION TO THE STUDY OF ANTISEPTICS.—At a meeting of the Académie des Sciences, held July 20, 1885, MM. A. MAIRET, PILATTE, and COMBEMALE made a report on the effect of carbolic acid and resorcine upon the higher forms of life. The phenomena observed from the action of resorcine are similar to those produced by carbolic acid, differing only in the following points:

1. Resorcine is more toxic. When injected in a strength greater than one and a half grains to every two and a half pounds, by weight, of the animal experimented upon, death ensues.

2. The saliva, which is very abundant, and the expired air, do not contain resorcine.

3. After the injection of resorcine the temperature falls a little more than under the influence of carbolic acid; sensibility is more blunted, and weakness is considerable.

4. Autopsy shows congestion and inflammation on the part of the spleen, pancreas, and mesentery, which have not been observed in experiments with carbolic acid.—*Gazette Hebdomadaire de Méd. et de Chirurg.*, July 24, 1885.

PROGRESSIVE TABETIC PARALYSIS.—DR. EMILE DEMANGE gives the following résumé of his study of progressive tabetic contracture:

1. There are reasons for describing a special form of tabes with contracture, distinct from spasmodic tabes, and from amyotrophic lateral sclerosis, but with which it offers numerous points of resemblance.

2. This form has been observed in extreme old age—after sixty-six years.

3. It depends for its origin upon a general atheromatous condition of the spinal bloodvessels.

4. Anatomically it is characterized by a diffuse interstitial sclerosis of vascular origin, in different portions of the spinal marrow, but more especially in the lateral cords, without, however, remaining limited to this system alone.

5. Clinically, it holds a middle place between spasmodic tabes and lateral amyotrophic sclerosis.

6. This form of disease we designate by the title of *progressive tabetic contracture of the atheromatous.*—*Revue de Médecine*, July, 1885.

EXPERIMENTAL STUDY UPON THE POSITION IN THE BLADDER OF OBLONG FOREIGN BODIES.—DR. HENRIET, after a series of experiments to determine the position of oblong foreign bodies in the bladder, recites the following conclusions:

1. Oblong foreign bodies when introduced into the bladder tend generally to assume a transverse position. This tendency is explained by the constancy of the transverse diameter of the viscus.

2. However, when the bladder is distended, the foreign body may take various positions, in every direction, uncertain and variable with the movements of the viscus, and not at all to be foretold.

3. When the length of the foreign body exceeds three or four inches, and it is sufficiently resistant to be unable to accommodate itself to all positions, it can only be received in a bladder more or less filled, and will lie in either the vertical or oblique diameter.

4. When foreign bodies are of moderate size and capable of being accommodated in any diameter, they may float in the viscus when it is full of urine, if their specific gravity permits. But hollow bodies, such as the ends of catheters, etc., become filled with fluid and always occupy the bottom of the organ.—*Annales des Maladies des Organes Génito-Urinaires*, July, 1885.

SURGICAL INTERVENTION IN DISLOCATION OF THE CRYSTALLINE LENS.—DR. DEHENNE, in a communication read at the Société de Paris, June 13, 1885, gave the following résumé of the conditions justifying surgical interference in dislocation of the crystalline lens:

1. Extraction of a luxated crystalline lens should only be attempted when the luxation is in front of the iris.

Digitized by Google

2. In every luxation posterior to the iris, no effort should be made at extraction.

3. If the patient suffers no pain, no interference with the condition should be made at all.

4. If there are symptoms of glaucoma exhibited, two cases are to be distinguished:

a. All perception of light is lost. Enucleation is necessary.

b. The media and the deep membranes are intact. It is necessary in the first place to practise a *sclerotomy*.

If accidents recur, remove the lens from the region dangerous to the eye, and, as a last resort, perform enucleation.—*L'Union Médicale*, July 5, 1885.

OSMIC ACID INJECTIONS IN TRIGEMINAL NEURALGIA.—DR. SCHAPIRO, in a recent lecture before the St. Petersburg Medical Society, gave an account of the chemical and therapeutical history of osmic acid, commencing with the discovery of the metal osmium in 1804 by the English chemist, Smithson Tennant, and concluding with his own observations made during the latter half of 1884, in the ambulance of the Imperial Philanthropic Society, when he employed injections of osmic acid in eight cases of trigeminal neuralgia, all of them severe, very obstinate, and of long standing. Of these cases five were cured, two improved, and one derived no benefit from the treatment. The formula used by him was—℞ Acidi osmici, 0.1; aquæ dest., 6.0; glycerini chemice puri, 4.0. This he found kept well for two or three weeks; while the simple watery solution began to become brown in three or four days, and afterwards turned black, and was then useless. As one gramme costs four roubles (eight shillings), being thus four times as dear as gold, it is of considerable importance to make use of a solution which will keep. The writer also found no dark specks in his solution such as are to be met with in that used by Neuber. The dose injected was at first five drops, afterwards more, the medium dose being eight drops. The only time when any unpleasant symptom occurred was in the case of a highly nervous lady who had been subject to epilepsy, and in whom the injection induced an attack of faintness very similar, in Dr. Schapiro's opinion, to the *petit mal*, and he suggests that with nervous patients the possibility of the occurrence of faintness should be borne in mind. The only case in which no improvement followed the treatment was that of a lady whose case was diagnosed by Professor Erb as hysterical neuralgia, and who suffered from severe pain in the neck and back of the head, and was believed to have some central lesion. In her case a single injection was followed by increased pain, and she refused to allow any more injections to be attempted. Dr. Schapiro, not having observed any evil local effects such as were described by Lichenstein (sanguineous bullæ, scabs, tedious boils), does not hesitate to inject under the skin of the face. He does not at present go deeply into the theory of the action of osmic acid, though he intends to study this experimentally; but he remarks that its most important action is to cause inflammation of the terminal nerve branches, it narcotic effect being of a secondary nature only.—*The Lancet*, August 1, 1885.

PUERPERAL CONVULSIONS WITHOUT ALBUMINURIA.—DR. N. VUCCINO, of Rodosto, writing in the Constantinople *Gazette Médicale d'Orient*, gives the case of a lady usually enjoying excellent health, except for occasional hysterical attacks, who in the fourth month of her first pregnancy was seized with a severe frontal hemicrania of quotidian type. At the end of the sixth month she was awakened one night with intense pain in the head, followed by a slight convulsion affecting the upper extremities. In the morning the writer found her suffering from general convulsions, consciousness being lost, and a bloody froth issuing from the mouth; the pulse was small and hard; but the urine was then, and continued to be, perfectly normal. Various methods of treatment having proved fruitless, it was decided to bring on the labor, which was done by injecting hot water (32°). After this had been continued for three hours and a half, the os uteri became fully dilated, and a dead child was shortly afterwards expelled. The convulsions ceased as if by magic, and in twelve days she was able to resume her household occupations. She afterwards enjoyed good health till the eighth month of her second pregnancy, when convulsions reappeared with greater intensity than before. Chloral and chloroform proving inefficacious, the continual hot vaginal douche was again employed. In consequence of the irregularity of the contractions of the uterus forceps were required. The convulsions ceased five hours after delivery, and in seventeen days she was again in her normal condition. She subsequently became pregnant for the third time, and during the second month suffered from some premonitory convulsive symptoms, which were increased by vaginal examination; these came to an end on the patient aborting. The author considers the case interesting, as showing how convulsions, due, as he believes, to a highly nervous condition of the uterus, may simulate those connected with renal and urinary mischief.—*The Lancet*, July 18, 1885.

THE USE OF HOMATROPINE AS A SUBSTITUTE FOR ATROPINE IN ESTIMATING LESIONS OF REFRACTION OF THE EYE.—MESSRS. W. LANG and J. W. BARRETT, after a careful clinical study of the use of homatropine as a substitute for atropine in ascertaining lesions of refraction, conclude:

1. That in the majority of cases where it is required to estimate the refractive condition of the eye atropine need not be used, but that a 2 per cent. homatropine ointment or solution applied in the manner indicated will answer equally well.

2. That the effect will pass off in from one to two days, but that if the patient be hypermetropic or emmetropic, and is desirous of avoiding the period of paresis of accommodation,

3. One or two applications of 0.8 per cent. solution of eserine just after the examination is finished will give him fair near vision until the effect of the homatropine is beginning to pass off.—*Medical Times*, July 18, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, AUGUST 15, 1885.

THE INTERNATIONAL MEDICAL CONGRESS.

WE invite careful attention to a letter appearing in another column, which has been received from Sir James Paget, who, as the immediate predecessor of the lamented Panum in the Presidency of the Congress, and as a member of the existing Executive Committee, speaks in reference to the organization of the next Congress with the highest authority. This letter commends itself to the thoughtful consideration of every physician who has the true interest of the American profession at heart, and it will give light to some who desired more authoritative information than they have yet possessed to guide correctly their future course of action.

It has been asserted by the editors of one or two medical journals that the Executive Committee of the last International Medical Congress no longer exists, that therefore the Congress must meet next in this country, and hence, that the American Medical Association plan must be adopted and supported. We have now information from members of the Executive Committee of the Copenhagen Congress, that that Committee is considered to be still in existence, that it still has work to do, and that it will by no means hesitate to assume the responsibility of ordering that the Congress shall meet in Europe instead of this country in 1887, in case it considers that such change of place of meeting would be for the interests of the Congress. And if it does issue such a notice there can be no doubt that it will be obeyed.

Of this Committee Sir James Paget is one of the most prominent and influential members, and hence his opinion demands the most serious consideration. This opinion is clear and straightforward. "*Certainly it was not expected that the Congress would be regulated with any degree of exclusiveness by the members of one medical association, however numerous, and I think it quite as certain that, if this had been thought possible, the proposal that the next meeting should be held in the United States, would not have been adopted.* I am sorry also to feel sure that if the Congress be not supported by the eminent men who have now declared that they will take no part in it, the members of the profession in this country who will attend it will be very few."

We consider it as now certain that the European members of the Congress have, through their Executive Committee, the power to prevent any material interference with the organization and work of the Congress itself, but, while this does away with our fears lest the progress and usefulness of these great international scientific gatherings should be checked by the action in this country, it increases our anxiety as to the effect of this discord upon our reputation abroad, and on our associations at home.

The action of the Original Committee,—of the American Medical Association,—and of the New Committee, is now generally understood; and there does not seem to be much use in further comment and criticism upon what is past. The important question now is as to the future. Is there any way by which the impending disgrace can be averted? If there is, it must be such as will induce those who have withdrawn from the organization to return and coöperate heartily. To the best of our knowledge and belief, derived from an extensive correspondence and from personal interviews, there is but one way to do this, viz., by dropping the Code question entirely, confirming all the appointments of the Original Committee, and leaving to the enlarged Committee which it created, including the Presidents of the Sections, the work of making additional appointments, completing the organization, and carrying out the work to its completion. If this be done, we believe that questions of appointments, etc., will be settled to general satisfaction, and that, although the difficulties of the work will be greatly increased, the Congress will be, what we all desire it should be, a great success.

If this be not done, we do not believe that the Congress will meet in this country in 1887.

PEPTONURIA.

WHATEVER may be the value which will ultimately attach to the so-called delicate tests for albumen which have been introduced into urinology during the past three years, one of the most useful purposes they will have served is the calling of attention to the possibility of the presence of peptone in the urine. And, although, as a result of such attention a vast amount of information has been acquired in rela-

Digitized by Google

tion to peptonuria, it is probable that we are still on the threshold of such knowledge. Indeed, we may go further and say that as yet we know not whether our information is altogether correct, or whether we may not even be compelled ere long to give up much of it and substitute it by other. At the same time it is our duty to our readers to furnish them with an accurate statement of the recent advances in medical knowledge, and we propose herewith to give a summary of what is now known concerning peptonuria and the tests therefor.

In the first place, it is well known that peptone is a proteid substance which is the final result of the digestion of albuminous food by the agency of the gastric juice in the stomach and by the pancreatic fluid in the duodenum. It may also be produced from albumen by the continued action of acids and alkalies, and it is said, also, by the decomposing action of bacteria, and the long-continued operation of a temperature of 268° to 290° F. It differs from albumen and hemialbumose or propeptone in that it is not precipitated by heat or nitric acid, by acetic acid combined with chloride of sodium, or with cyanide of potassium. Like albumen and propeptone, it is precipitated by tannin, corrosive sublimate, phosphorwolframic acid, Millon's reagent, and by potassiomercuric iodide and picric acid, both of which are among the recently suggested delicate tests for albumen; but when precipitated by the latter reagents it is redissolved by heating. It is characterized by the purple reaction its solution strikes with sodic hydrate and a little salt of copper. The sensitiveness of this so-called "biuret" reaction is increased by certain coloration of the fluid, and especially the yellow. So delicate is it that a solution so weak as 1 part in 1000 responds promptly. This reaction is shared by propeptone, while albumen produces only a blue coloration, under no circumstances a red or violet. It has been suggested that peptone bears the same relation to albumen as grape sugar to starch—that is, it is a hydrate of albumen.

Peptone is not present in healthy blood or normal urine, and even during digestion the portal vein contains but traces of it. Injected into the blood, it disappears from it very quickly, a certain proportion reappearing in the urine, while some is taken up by various organs of the body. These organs also appear to retain any small excess which may have been introduced into the blood from over-ingestion of meat. It would seem, therefore, that it is converted into albumen at the moment it is absorbed into the circulation, and is incapable of taking the place of albumen in the blood, although this has been alleged by Plosz, Maly, and Adamkiewicz. During health, too, the various organs of the body contain traces of it, but it is a constant constituent of pus, as was first shown by Hofmeister. It was found by Salkowski to be abundantly present in the leucæmic liver and spleen.

In testing for peptone in urine by Hofmeister's method (*Zeitschr. für Physiol. Chemie*, 1880, Bd. iv. S. 260, und Bd. v. 1881, S. 73), the peptone is precipitated by solution of tannic acid, either with or without previous treatment by acetate of lead, for the purpose to be named below. The precipitate, after twenty-four hours, is thrown upon a filter to which some tannic acid and magnesium sulphate have been added; the object of the latter being to prevent the peptones from being washed out of the precipitate. The precipitate is now thoroughly mixed in a capsule with saturated baryta water, and after the addition of a fragment of solid baryta heated to boiling. If care is not taken to mix intimately the precipitate with the baryta, resinous masses form during the heating, which interfere with the proper action of the baryta. After a few minutes the mixture is filtered, baryta water being again added, and thoroughly shaken with it until the fluid filters off from the dark colored precipitate, either colorless or slightly yellow. It now contains no tannic acid, as will appear on neutralizing the fluid and adding chloride of iron.

To the filtrate are now added a few drops of a solution of sulphate of copper, the mixture well shaken and filtered. If the filtrate is a bulk of four to five centimetres thickness, and shows a red or violet color, peptone is present.

The method with tannic acid also gets rid of propeptone, or hemialbumose.

v. Jaksch, who has made a very extensive clinical study of peptonuria, the results of which were published in *Zeitschrift für Klinische Medicin*, 1883, prefers to precipitate the peptone by phosphorwolframic acid, instead of tannic acid, by the following process, also suggested by Hofmeister: The urine, mixed with about one-tenth its bulk of hydrochloric acid, is treated with solution of phosphorwolframate of sodium, acidified with hydrochloric acid and filtered promptly, since in standing there is deposited on the slightly colored precipitate a layer of reddish flocculi, whence the coloring matter subsequently disappears. The precipitate is washed with a solution of sulphuric acid, three to five per cent. strong, then turned into a capsule, intimately mixed with baryta in substance, the mixture treated with a little water, and, after being warmed for a short time, filtered. The filtrate is then treated with copper solution as above. In this method no regard is paid to the presence of propeptone, and Salkowski advises that the urine be tested for this substance, and, if it is present, that it be removed by the process recommended by Hofmeister for the separation of albumen, which should, also, always be first separated in the following manner: 500 cubic centimetres of urine are treated with 10 cubic centimetres of a concentrated solution of ace-

Digitized by Google

tate of sodium, and a concentrated solution of chloride of iron added, until the fluid acquires a permanent red color. The strong acid reaction is now neutralized, or nearly neutralized, by an alkali, condensed by boiling, and, when cool, thrown on a filter. If the iron and alkali are added in proper proportions, the filtrate is free from iron and albumen, as may be shown by adding acetic acid and ferrocyanide of potassium. A trace of iron does not, however, interfere with the test.

Mucin, the presence of which is shown by a cloudiness which arises on the addition to urine of acetic acid alone, must also be separated, and this can be done by adding a solution of neutral acetate of lead, until a thick, flocculent precipitate is produced. Filtration removes both the lead and the mucus. This may be done at the very beginning of the process, as recommended by Hofmeister, and practised in each instance by v. Jaksch. It has the advantage also of simultaneously decolorizing the urine.

Solution of sulphate of copper and sodic hydrate, or, what has been recommended as a substitute, Fehling's solution, directly applied to the urine, without previous treatment, cannot be regarded as a reliable test for peptone. So that a trustworthy, ready method for testing peptones does not exist, unless we adopt that of Dr. George Johnson, with picric acid.

We have mentioned that peptones, like albumen, are precipitated by picric acid; but, unlike albumen, the precipitate thus obtained is redissolved on heating. The same is true, however, of the acid urates and vegetable alkaloids, among which quinine and its allied derivatives are conspicuous. It is well known that the administration of ten grains of any of these alkaloids will speedily so influence the urine, that picric acid promptly develops in it the characteristic opalescence of albumen, which, unlike albumen, also disappears on being warmed. As Dr. Johnson says, the sediment of urates is readily distinguishable from that of peptones by the microscope, because the former are found to be made up of large granules of urate of sodium and uric acid crystals, while freshly precipitated peptones appear quite homogeneous under the microscope; but when, having been dissolved by heat, they are reprecipitated on cooling slowly, they contain exceedingly minute granules, which exhibit very actively the dancing Brownian movement. If, however, the liquid be cooled suddenly, by plunging the test-tube in cold water, the precipitate does not become granular until it has been allowed to stand for some hours. The difference in the fresh precipitate with the vegetable alkaloids and that of peptone, according to Johnson, is, that it is finely granular, while the freshly precipitated peptones are homogeneous.

Hofmeister suggests, too, a shorter, but coarser, test for peptones, wherein the urine is treated with an excess of solution of acetate of lead and filtered. The filtrate, which should remain clear, on the addition of acetic acid and ferrocyanide of potassium, is treated with one-fifth of its volume of concentrated acetic acid. To this is added a solution of phosphorwolframate of sodium, acidified with acetic acid. If a cloudiness makes its appearance within the first five minutes, peptone is present. If the urine does not contain peptone, it will remain clear for an hour or longer.

Quantitative estimation of peptone may be made by the polarimeter, for the details of which we must refer our readers to the textbooks.

Hereafter we shall have something to say as to the clinical significance of peptones.

CHERON'S TREATMENT OF CHRONIC PELVIPERITONITIS.

THE treatment of chronic inflammation of the pelvic peritoneum is in many cases tedious, and often very unsatisfactory. The pain, the tenderness, and the inflammatory deposits—the last in some cases simulating new growths, and not unseldom mistaken for them—are very slow in disappearing in many cases under methods of treatment hitherto employed. In consequence of these facts, we look with great interest upon a plan of treatment which Chéron has employed with remarkable success, and which he publishes in the June number of the *Revue Médico-Chirurgicale des Maladies des Femmes*. He uses hypodermatic injections of the crystallized phosphate of soda. The solution, which should be freshly prepared and carefully filtered, is made of one part each of crystallized phosphate and of sulphate of soda to twenty parts of distilled water. The quantity used for an injection is one drachm; it should be injected into the subcutaneous connective tissue, not into the subdermic. The injection should be made slowly, and massage of the part made for a minute or two. The injections are to be repeated every six or eight days.

PUNNING IN MANIA.

DR. SAVAGE, in his recent work, *Insanity and Allied Neuroses*, speaks of "rapid verbal association, punning, and verse-making" in mania. In regard to punning, he unfortunately does not tell us that the insane punsters had, previous to their illness, been addicted to this indulgence, and probably it is just to conclude that it is to be considered a manifestation of their mental disease.

This is a very important statement, but we cannot suppose that punning is, as a rule, an indication of insanity. Homer did not disdain punning, for it will be remembered that the wily Ulysses thus deceived the monster Polyphemus. Excellent puns, too, have come down to us from the good old days

Digitized by Google

of Rome, while in modern times who can forget such manifestations of wit by Molière, Charles Lamb, and Thomas Hood? In our own country the most distinguished of literary physicians, rich in wit and wisdom, rich in fame, but richer in the love of all who know him, has occasionally contributed a sparkling pun to life's merriment. Another eminent literary physician who knows how to make fat and blood, also knows how to make a pun —one knowledge he has communicated to the profession, but the other he has not.

Of course, we cannot in the light of these illustrious examples for a moment think that all punsters are insane. But if a man makes bad puns—and we are sorry to say many puns are bad, bad because poor, poverty thus becoming a crime—is he to be regarded as crazy or criminal? There are not wanting those who unhesitatingly look upon such indulgence as one of the greatest crimes; a man who makes a bad pun is, according to them, ready for any minor wickedness, such as theft, arson, or murder. Others, indeed, go so far as to relegate all puns to dime museums and strolling minstrels. If one ventures upon the most innocent verbal play in their presence, he is soon made aware that he could with greater safety have trodden upon their corns, or spoken disparagingly of one of their most intimate friends, and is fortunate if he be not at once consigned to Coventry, or to Hades.

But let us be charitable; some one laughs at the weak punster's wit, some one applauds his effort; nay, he may, at times, "set the table in a roar"—truth compels us to say that at times "the table" roars most readily, and applauds boisterously the most trivial things. Now they who thus do, aid and abet the punster's immoral practice, and should be held to strict account at the bar of public opinion. He has become intoxicated by praise, like the village poet in Dr. Holmes's "Guardian Angel," who did not know how valueless his rhymes were until he attempted to sell them to a publishing house. He, himself, is possibly to be regarded as simply feeble minded in some cases, while in others it is probable that the indulgence is a manifestation of commencing insanity, and then a prompt removal to an institution for the insane, and not confinement to a gaol, is the proper remedy.

The view here taken will do more to repress the common practice of punning, than has the severe literary criticism to which it has been subjected. We wish to say, however, that the force of this criticism has been weakened by the inconsistent conduct of some of the critics. Sidney Smith, for example, asserted that puns were justly in very bad repute; and yet he, according to Southey, was "Joke-Smith to the *Edinburgh Review*," and certainly made many puns. This inconsistency between criticism and conduct is only to be explained by the fact that he was a preacher, not a practitioner. But returning, few men or women are willing to be thought crazy, and therefore they will avoid that which may excite suspicion. Dr. Savage has enlarged our knowledge of the disease, and opened the way for important reform.

So much for bad punsters The good ones will not be prodigal of their ware, but remember the wear advised by Jeffrey for one who has a blue stocking—a long petticoat.

HEMIALBUMOSE OR PROPEPTONE.

ANOTHER one of the proteid substances sometimes found in urine, and to which increased attention has been called by reason of the introduction of the so-called delicate tests for albumen is hemialbumose.

This substance is an intermediate product in the conversion of albumen into peptone, in the act of gastric digestion. It is therefore abundantly present along with albumen in the gastric contents, and, unlike peptone, is also found in the blood during digestion. It is identical with the albuminous substance known as Bence-Jones's albuminous body or Mulder's proteindentoxyd found by Virchow in the bone marrow in osteomalacia, and by Fleischer in normal bone marrow.

Hemialbumose, like albumen, is insoluble in alcohol; also insoluble in pure water, but very soluble in water containing only traces of acids, alkalies, or salts. It is not precipitated by heat from its watery solutions as is albumen, but if the solution be made strongly acid and concentrated salt solution be added thereto, it is precipitated. If the cloudy fluid be now heated it becomes transparent, but again turbid on cooling. A further large addition of salt maintains the precipitate in spite of heating. It is precipitated by pure nitric acid, but redissolved with the production of an intense yellow color on heating, and reprecipitates on cooling. An excess of nitric acid redissolves the precipitate even in the cold, with the production of the same orange-red color.

In these respects hemialbumose differs strikingly from both peptone and albumen. It is like peptone in that it exhibits the biuret reaction with an alkali and salt of copper, and like albumen in that it is precipitated by acetic acid and ferrocyanide of potassium.

In order to test the presence of hemialbumose the albumen must first be removed. This is accomplished by acidifying the urine with a few drops of acetic acid, adding about ⅙ its volume of concentrated salt solution, boiling, and filtering off the precipitate. The filtrate is then allowed to cool, and if a turbidity arises or is produced by the further addition of salt solution, which disappears by heating, and reappears with cold, propeptone is present.

Digitized by Google

Hemialbumose is removed from fluids by adding acetate of iron and boiling, or by boiling with hydrated lead oxide.

Hemialbumose was first found in urine by Macynter and Bence-Jones, in the disease known as osteomalacia, and by Lassar in artificial nephritis.

REVIEWS.

A MANUAL FOR THE PRACTICE OF SURGERY. By THOMAS BRYANT, F.R.C.S., Member of the Council and Court of Examiners of the Royal College of Surgeons; Senior Surgeon to and Lecturer on Surgery at Guy's Hospital; Memb. Correspond. de la Société de Chirurgie de Paris. With seven hundred and twenty-seven illustrations. Fourth edition, thoroughly revised. 8vo. pp. 1026. Philadelphia: Lea Brothers & Co., 1885.

THE most cursory examination of this edition bears out the claim that it has been "thoroughly revised," while a more careful scrutiny reveals that much new matter has been added, and the old, in a measure, rearranged, so that a more natural sequence has been secured. Unlike the third American edition, this fourth one is an exact reprint of the fourth English edition, although the American publishers call attention to the fact that Mr. Bryant "has seen fit to accept many of Dr. Roberts's additions" which appeared in the previous edition.

This book is essentially what it purports to be, viz., a manual for the *practice* of surgery. In consequence, little space is devoted to the theory of surgery, but enough is said to enable the reader to treat all ordinary surgical affections with due reference to their pathology. Much more than any such qualified praise is due to that portion treating of intestinal obstructions and their operative treatment, where the best of all teaching—that drawn from an extended personal experience—is given. Probably no surgeon has ever performed such a number of colotomies as Mr. Bryant, viz., eighty-two; and few have, therefore such a right to dogmatize as to the value of this operation. It may be well, therefore, to introduce the conclusions at which the author has arrived.

1. "That in all cases of cancerous stricture of the rectum or colon, including the annular, which are not amenable to lumbar colectomy or anal excision, right or left lumbar colotomy is strongly to be advocated, with the well-grounded hope of relieving suffering, retarding the progress of the disease, and of prolonging life for five or six years.

2. "That lumbar colotomy is valuable as a curative operation in syphilitic and simple ulcerations of the bowel which resist other treatment, including cases of recto-vesical fistula, and that it is remedial in examples of volvulus of the sigmoid flexure, as well as of obstructions caused by tumors.

3. "That to secure these advantages it is necessary for the operation to be performed before the pernicious effects of obstruction occur."

We have always viewed with special favor the whole section upon intestinal obstructions, but the additions and alterations in the present edition have much increased its value. There are some points, however, which we regret the omission of, but which we cannot here specify. The illustrations are unusually good, being both clear and at the same time artistic. We would call attention to the section upon "Tumors," which, although perhaps good from a clinical standpoint, is certainly not in accord with modern views. We refer especially to the author's teachings as to the sarcomata, which are termed "Semi-malignant." Now we are unacquainted with any more *wholly* malignant growths than certain of the tumors now universally termed sarcoma, and the histological characters of which the author correctly describes. We can neither then agree as to their *semi-malignancy*, nor with the statement that they solely "return either in the spot from which they originally sprang or from its immediate neighborhood;" some of them do, but as a class, they behave far differently. It is true that the lymphatics usually remain uninvolved, but by means of the blood-current systemic infection too often occurs with frightful rapidity. Perhaps the author would call such tumors encephaloid carcinomata, but histologically from his own descriptions, they are sarcomata, and are universally so considered by pathologists. This perhaps is only a minor blemish, but it is apt to mislead the inexperienced, and is one, therefore, to which attention should be called.

Although written chiefly from an English standpoint, Bryant's *Surgery* is a fair work in which due credit is given to both foreign and American surgeons. It is peculiarly well fitted for the student or busy general practitioner who wishes to be taught the views of surgery held by foreign surgeons, but can hardly supersede text-books written by and for Americans. With these latter alone, the student is apt to obtain a too circumscribed view of surgery, but if he will supplement his reading by some such work as that under review, without extended study he will be enabled to gain something like a cosmopolitan view of both the science and art of surgery.

YOUNG FOLKS' PHYSIOLOGY—OUR BODIES, AND HOW WE LIVE; AN ELEMENTARY TEXTBOOK OF PHYSIOLOGY AND HYGIENE, FOR USE IN THE COMMON SCHOOLS, WITH SPECIAL REFERENCE TO THE EFFECTS OF STIMULANTS AND NARCOTICS ON THE HUMAN SYSTEM. By ALFRED M. BLAISDELL, M.D. 12mo., pp. vi. 285. Philadelphia: Cowperthwait & Co., 1885.

A LARGE number of States have recently passed laws requiring that, in the Public Schools, physiology and hygiene shall be taught with special reference to the effects of alcohol and narcotics on the human system. This demand has produced quite a large crop of books—good, bad, and indifferent—most of them written evidently to catch the market. They bear evidences of haste, and even in some cases of ignorance. We pointed this out in one notable case in our issue of March 15, 1884 (*Brand's Physiology*).

The present volume is an excellent example to the contrary. It is the work of a man who knows what he is talking about, and who also has the knack of the true teacher. His ideas are clear, and his language perfectly simple, so that any child of ordinary intelligence can understand him. Moreover, he has Agassiz's true idea of the method of teaching. He is not satisfied with

Digitized by Google

a dry description, but has appended to the book a good chapter of "experiments," such as any teacher or scholar can easily make. This is a cardinal point. It is one thing to tell a pupil about the "animal" and "earthy" matter in a bone, but it is quite another thing to have him get two bones and burn one and soak the other in acid and see the results of the two processes for himself. The whole series of these experiments is equally simple and effective, for they direct the teacher and pupil in the method of studying the main facts of anatomy and physiology in the same objective way. We would suggest, however, that a sheep's eye would be, as a rule, more easily accessible than that of a codfish when it is desired to dissect that organ. An excellent glossary and a full index complete this well-written and useful volume, which we can commend unreservedly to school boards and teachers as just the thing they will want.

In the most difficult part of the book—the due appreciation of the effects of alcohol and tobacco—the author seems to have been very happy in stating the facts in a clear and non-partisan manner. He has shown the bad effects of both—especially of alcohol—without on the one hand trying to mitigate their evils, or, on the other, to exaggerate them for a purpose, as would be done by the fanatic. The book will do good most of all by its entire fairness.

We would like also to point out two or three errors. Thus, the gluteal muscles are spoken of as on the back of the thigh; Macé is written twice at least without the accented é; and, by a curious blunder, the pupil is spoken of as the "apple of the eye," whereas when we use that expression we mean by "apple" the whole "ball" of the eye.

We notice, also, as a merit, the reference to the *American Health Primers*, *Wilson's Hygiene*, and numerous other excellent and standard works as "collateral reading."

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, June 4, 1885.

THE PRESIDENT, B. F. BAER, M.D., IN THE CHAIR.

DR. BERNARDY reported a case of

GESTATION IN A SARCOMATOUS UTERUS, SIMULATING EXTRAUTERINE PREGNANCY.

On October 3, 1884, he was requested to visit Mrs. McG., delicate, age about thirty, married six months. She was said to be suffering from a cold. He found the patient up. Temp. 105°; pulse 130, with a high fever and a severe cough. Examination of the lungs revealed double pneumonia. At the same time, noticing the abdomen prominent, he inquired, and was informed that pregnancy was five months advanced. The abdomen was rather large for that period. On Sunday, October 5th, she complained of a sharp pain in the right inguinal region, the pain was excruciating, and demanded the administration of large doses of morphia before any relief was obtained. He found the right inguinal region filled by an immense growth reaching almost to the lower border of the liver. The uterus or what appeared to be the uterus was enlarged, and pushed well toward the left side. On vaginal examination, found the right side of the pelvis filled by a growth. At first thought he detected fluctuation, but closer examination showed it to be hard to the touch. The uterus was jammed well towards the left, and was immovable, the neck somewhat absorbed, the os tilted up behind the pubis. To reach it the finger had to be passed well upward; it was closed and soft. The patient had never had any uterine trouble, menses always came without pain; they never appeared after her marriage, which occurred one week after a period. Her health remained good for three months after marriage, when, while out walking, she was suddenly seized with a sharp lancinating pain in the right side of the abdomen. The pain was so great that she almost fainted, but being a woman of strong will, she finally, after suffering terrible agony, reached home, and went to bed. No physician was called in; next day there were slight traces of blood on her night dress. Under absolute rest the pain subsided, and at the end of a week she was about her household duties. The pain in the side returned if she over-exerted herself. Sexual intercourse was painful, and was followed by traces of blood the next day. Believing that the symptoms pointed to either extrauterine pregnancy, or a tumor complicating pregnancy, he asked Dr. Goodell to meet him. By the time the consultation was held, October 8th, a severe attack of peritonitis had commenced. This complicated matters as a close examination was impossible. On account of the distended and painful condition of the abdomen, it was impossible to trace any outline of the growth or uterus. It was decided that the symptoms and history pointed to extrauterine pregnancy, but that undoubtedly the uterus contained something, whether a tumor or child, in the present condition of the patient, it was impossible to decide; the leaning was toward a pregnant uterus. By October 16th the peritonitis was under control, the lungs no better. October 19th he was sent for, the messenger stating that there was a renewal of the peritonitis. He found the patient in active labor, the fœtus descending rapidly. In half an hour labor was completed. I readily detected the large growth filling the upper portion of the right side of the pelvis; the uterus was surrounded by a hard growth. The cervix was hard. From this time the lungs improved, but she remained extremely weak, and there was a constant dribbling of blood from the vagina. November 3d, the growth was still present and the cervix hard, and I began to think of malignant disease in connection with the tumor. I had applied, night and morning, to the abdomen, ung. hydrarg., belladonna, and iodine, equal parts. This seemingly had the effect of causing the absorption of the large growth, but the mass surrounding the uterus remained the same. November 27th, vomiting occurred and was arrested with difficulty; a bloody discharge from the vagina and a constant sore feeling over the region of the uterus, which was still toward the left side. The patient's condition was not good, she was extremely weak; the slightest exertion would exhaust her and bring on bleeding from the uterus. December 26th he found her suffering from pleurisy, the left pleural cavity full of fluid. January 1st abdominal dropsy had set in. A consultation with Dr. Goodell was held. A positive diagnosis of malignant disease was made.

Prognosis.—Death at any moment. She died suddenly the same evening while talking to her husband.

Digitized by Google

Post-mortem examination, by Dr. A. E. Roussel, twenty-four hours after death; patient greatly emaciated. *Thorax:* A large amount of effusion completely filling up the left pleural cavity, while the cavity of the right side was partially filled; both lungs were compressed upwards. No adhesions. On section the lungs appeared mottled, and were hepatized in general appearance, but were otherwise healthy. *Heart:* On opening the pericardium found a moderate amount of serous fluid, vegetations on mitral valve—weight eleven ounces. *Abdomen:* Entire cavity was greatly distended with dark fluid full of broken-down lymph. The intestines were forced upwards; there were slight evidences of beginning peritonitis. A portion of the ileum on the right side presented a black unhealthy appearance bordering on gangrene. The uterus was increased in size. The outer surface presented an irregular mottled appearance, large veins covered its surface; at the fundus there appeared a spot about one inch in diameter, of a bluish tinge. On pressure by the finger the surface readily broke. Underneath was a cavity about the size of a large hickory-nut which did not communicate with the interior of the uterus. On opening the uterus its cavity was found to be almost obliterated, the tumor seemed to have entirely absorbed the true uterine tissue with exception of the neck. In the body of the tumor were observed small masses or growths varying in size up to that of an egg. The ovaries were small and seemed to have participated in the general disease. Microscopic examination proved the tumor to be of the adeno-sarcoma variety.

At first he was convinced that he had a case of extra-uterine pregnancy; but the peculiar hardness of the tumor made him doubtful. Here was a patient that had never had any uterine ailment. Marries, becomes pregnant; at the end of the third month, without any premonition, while quietly walking, is seized with pain of an excruciating nature in the right side, goes to bed and remains quiet, the next day blood flows from the vagina. She remains comparatively well for two and a half months more, when she is again suddenly seized with pain in the same side, followed by peritonitis. A tumor is found in the affected sides, the uterus is enlarged, but not sufficiently so for a five and a half months' pregnancy, the os giving no signs of that softening which should accompany pregnancy. Could we have a group of symptoms more allied to those of extrauterine pregnancy?

DR. J. M. KEATING made some remarks on

INFANT FEEDING.

He said: At my request, Dr. Charles Potts has instituted a series of experiments which have a decided practical value, and we hope to present them to this Society at an early date, but I desire to place on record a statement of the results so far reached, which appear to be interesting and important. The question often arises, Is it of advantage, or not, for an infant to be partly nursed and partly bottle-fed? What action has milk upon starch, if any? To answer this the following tests were made: (1) Sample of milk composed of the milk of several women. A quantitative estimation of the sugar in it by Fehling's method showed 6.84 per cent. Ten c.c. of this milk were then taken and ½ gramme of powdered starch added, allowed to stand at a temperature of 99° for thirty minutes, after which 5 c.c., diluted with 45 c.c. of distilled water, were tested and showed 8.62 per cent. of sugar. The other 5 c.c., after standing sixty minutes, gave 9.09 per cent. (2) Another sample, found to contain 7.14 per cent. of sugar, had a ½ gramme of powdered starch, as in No. 1. In thirty minutes it gave 9.803 per cent. of sugar in 5 c.c. The other 5 c.c., after remaining sixty minutes, gave 8.62 per cent. Possibly part of the sugar deposited and was drawn off with the first 5 c.c. (3) Another sample showed 6.32 per cent. of sugar, and, after adding the starch as before, gave in the first 5 c.c. 8.19 per cent. The next 5 c.c. 7.93 per cent. These investigations showing that woman's milk gave an increase of sugar after digesting with starch. (4) A sample of cow's milk was tested and found to contain 3.87 per cent. of sugar; to this was added a ½ gramme of starch to 20 c.c. At the end of thirty minutes 5 c.c diluted with 45 c.c of distilled water showed no increase of sugar. (5) A sample of cow's milk gave 4 per cent. of sugar, and was treated as before, but at the end of thirty minutes, and then sixty minutes, it gave the same result. (6) Another sample of cow's milk gave 3.703 per cent. of sugar; was treated as before with the same amount of starch. In thirty minutes 5 c.c. gave same result; in sixty minutes 5 c.c. gave same result. These investigations showing that cow's milk gave no increase of sugar after adding starch. Does the acidity of cow's milk prevent the sugar change? Does the sugar change continue in an acid medium? (7) Took another sample of human milk—from one woman. It yielded 6.25 per cent. of sugar; added starch as before. In thirty minutes 5 c.c. gave 7.14, and in sixty minutes 5 c.c. gave 7.6 per cent. Took 10 c.c. of this milk (6.25 per cent. sugar) and added a few drops of chemically pure dilute hydrochloric acid, enough to acidulate it faintly, and then added ½ gramme of starch, and let it stand as before. In thirty minutes 5 c.c. gave 6.41 per cent., and in sixty minutes 5 c.c. gave 7.35 per cent. of sugar. (8) Another sample of woman's milk, without starch, gave 6.17 per cent.; with starch, 7.24 per cent, Ten c.c. of the same acidulated with hydrochloric acid, chemically pure, diluted, gave in thirty minutes 7.35 per cent. In these tests 10 c.c of Fehling's solution were used with 40 c.c. of distilled water.

If future investigations prove the correctness of these statements, we may safely assert that the nursing woman may supplement her breast milk with some well-prepared, digestible form of food containing a small quantity of starch advantageously, and also that the amylolytic ferment will remain active in the slightly acid stomach of the infant.

CHICAGO GYNECOLOGICAL SOCIETY.

Stated Meeting, May 29, 1885.

THE PRESIDENT, H. P. MERRIMAN, M.D., IN THE CHAIR.

DR. FRANKLIN H. MARTIN presented an inaugural thesis entitled

THE NORMAL POSITION OF THE UTERUS AND ITS RELATION TO THE OTHER PELVIC ORGANS,

in which he opposed the extreme theories of Schultze, Fritsch, and Savage, for the following reasons:

1. In extreme anteversion, the wave impulse would

Digitized by Google

strike the posterior broad surface of the body of the uterus, and drive it down upon the bladder and anterior wall of the vagina, while, on the other hand (the perpendicular theory of Savage), the anterior broad surface of the body would receive the impulse to an equal disadvantage, displacing the uterus backward and driving the cervix downward, while if the uterus occupied the position between these two extremes, the narrow crest of the fundus would receive the impulse in the line of the axis of the uterus and all the force would become equally distributed through all of its supports. Here, too, the organ would not so directly receive the whole impulse, as it would be equally dispersed upon its sides and the posterior ligaments and anterior supports, and its lateral attachments would receive to an equal extent, their portion of the impulse.

2. The manner in which the bladder collapses, to our mind, precludes the possibility, or at least the probability of the uterus occupying normally the position of extreme anteversion. The bladder, when collapsed, or when empty, is a triangular-shaped body—not flat like a plate: the base corresponding to its peritoneal surface, the apex corresponding to the urethra. The posterior or inferior surface corresponds to the anterior wall of the vagina, to which it is intimately attached; the anterior wall corresponds to the symphysis, to which it is loosely attached. It is readily seen, then, that the bladder distends only in the direction of the peritoneum, or its one free surface. According to the extreme anteversion theorists, the free surface of the bladder and the uterus are in apposition. If such be the case, the uterus changes its position constantly, as the bladder normally relaxes or contracts,—this seems to us very improbable. We believe that this space is usually filled with the light coils of the small intestines.

3. The broad ligaments receive their external attachments at a point about equidistant from the centre of the sacrum posteriorly, and the pubic junction anteriorly, in such a way as to divide the plane of the brim of the true pelvis into about equal halves. If the body of the uterus occupies a position in the centre of the pelvis on a direct line with the ordinary attachments of these ligaments, which it is at least rational to believe is the case, it occupies a position between the perpendicular of Savage, and the extreme anteversion of Fritsch.

4. With extreme anteversion, the cervix, with the fundus occupying a position behind the symphysis would necessarily have to occupy a position far back in the pelvis, within three-fourths of an inch of the sacrum,—with a normal conformation of parts, this is impossible without interfering with the rectum.

5. If we take the measurements of Foster and Litzmann into consideration, we can at once demonstrate the impracticability of the position given by Savage—*i. e.*, the perpendicular. The cervix occupies a position, normally at a distance of one and one-half inches from the sacrum, the rectum intervening. It is impossible for the uterus to assume anything like a perpendicular with the cervix in this position, on account of the anterior curve of the sacrum above, which necessitates an anterior version from the perpendicular of at least fifteen degrees.

PROFESSOR W. W. JAGGARD was pleased with the selection of the topic, and the method of discussion, but did not agree with Dr. Martin in all his conclusions. Bandl had made a correct statement of the diversity of opinion upon this subject, in his essay on "The Normal Position and the Normal Relationship of the Uterus, and the Pathologico-anatomical Causes of the Symptom of Anteflexion" (*Archiv. für Gynækologie*, Band xxvi. Heft 3, 1884), read before the Gynecological Section of the Versammlung deutscher Naturforscher und Ærzte in Freiburg, September, 1883. "In the course of time, almost every position of the uterus, with the exception of prolapse, has been accepted as the normal by different anatomists and gynecologists, and particularly by the more eminent ones."

Kölliker (1882), from a series of examinations of the cadavers of girls, from ten to eighteen years old, has concluded that the uterus is not bent, nor curved upon itself, but is straight, and that its long axis corresponds with the principal axis of the small pelvis. Its position is variable within certain limits, depending upon the condition of the bladder and rectum. This opinion coincides closely with judgments of Kohlrausch (1854), Le Gendre (1868), Freund, Carl Braun (1857), J. Marion Sims (1855); Langer (1881). Professor Paul F. Mundé, in his recent excellent work on *Minor Surgical Gynecology*, favors these views to the extent, that he says, "with the woman in the recumbent position, the examining finger is unable to touch the body of the uterus before or behind the cervix, if the uterus is normally situated."

Bandl, in the paper to which allusion was made, confirms Kölliker's view. The evidence he furnishes is of a high order. His methods of investigation were:

1. The attentive examination of living women.

2. Examination and observation before and during the operation of laparotomy.

3. The bimanual examination of the organ in cadavers, before and after abdominal section.

4. The comparative anatomical examination of many *uteri*.

DR. PHILIP ADOLPHUS thought, with Emmet, that "there is no common standard by which to determine the proper position for the uterus in all women, but that in each individual there is a point, or plane, in the pelvis which the uterus should occupy when she is in a state of health and not pregnant." He referred in detail to Emmet's "normal or health line," and to the pathological character of displacements above or below this line. It is a matter of relative insignificance whether or not the long axis of the uterus coincides with any particular pelvic axis. In the concrete case, the sensation of the individual will indicate a normal or abnormal position.

PROF. DANIEL T. NELSON said that the uterus is fixed in a position of unstable equilibrium by the annular and other ligaments. It can move to a certain degree in every direction, and return to its original, normal position. Displacement above or below Emmet's "health line" is productive of symptoms, if the uterus remains fixed in such a position, as is usually the case when violence causes the dislocation. Departure from the principal axis of the pelvis is a comparatively insignificant movement, viewed absolutely. The vagina and perineum are not primary supports of the uterus, and only assume this function when, as the result of the relaxation of the proper uterine supports, the organ is displaced downwards. This secondary character of

Digitized by Google

the vaginal and perineal support was capable of demonstration by the examination of a woman in the erect attitude. Upon coughing or sneezing the uterus will descend and receive support from the vagina and perineum, only to regain its original position when the excitant is removed. This remark applies exclusively to normal organs in normal position.

He wished to emphasize the statement that the rectum is not the normal receptacle for the feces. Anatomy and physiology teach that in the normal condition the gut is empty up to the sigmoid flexure. The sigmoid flexure is a sort of valve to retain feces. He narrated the history of a case of retention of urine in a puerperal woman, in which the bladder was displaced towards the left iliac fossa, while the uterus was directed towards the right.

PROF. CHARLES WARRINGTON EARLE related the history of a case of retention of urine in a puerperal woman, the bladder displacing the uterus upwards and backwards. Upon the introduction of a catheter, four quarts of urine were evacuated and the pelvic viscera returned to their normal relations.

DR. EDWARD WARREN SAWYER said the uterus had great latitude of movement antero-posteriorly and laterally; elevation above or depression below the normal plane, even to a slight degree, was productive of pain. The introduction of a pessary, which merely elevated the uterus when partially prolapsed, without altering flexion, is sufficient in many cases to afford complete relief. While a student he had taken plaster casts of the vagina. Such casts were of uniform shape, while they differed in size. They were curved, convex posteriorly, concave anteriorly. They were never shaped like an S. The curve did not correspond to that of the anterior surface of the sacrum, but to the floor of the pelvis.

DR. H. T. BYFORD thought Dr. Sawyer's experiments were faulty. When plaster of Paris was injected into the vagina, with the rectum empty, the vagina would act exactly as the rectum would under similar conditions.

CORRESPONDENCE.

THE ORGANIZATION OF THE INTERNATIONAL MEDICAL CONGRESS.

[THE accompanying letter has been received in this city, and is published for the information of the American profession, as it gives an authoritative statement concerning the manner of organizing preceding congresses, as well as the general understanding at Copenhagen in reference to the organization of the Washington Congress.

Sir James Paget, as is well known, is a member of the present Executive Committee of the Congress, and the President of the London Congress, and the immediate predecessor of the late Prof. Panum in the Presidency of the Copenhagen Congress, and he, therefore, speaks with the highest authority concerning all matters which pertain to the rules and customs of the Congress.—ED.]

1 HAREWOOD PLACE, HANOVER SQUARE,
LONDON, July 22, 1885.

DEAR DR. HAYS: I am very sorry to learn from some of your journals, as well as from letters which I have received, that there are serious differences of opinion among the members of our profession in your country as to the arrangements to be made for the International Medical Congress which it is proposed to hold in Washington in 1887. The deep interest which I feel in the Congress makes me venture to write to you in the hope of helping towards a right decision of some of the questions in dispute; and chiefly, by stating what I believe to have been the custom at former meetings.

I believe that a principal question relates to the authority, if any, which was given by the Congress at Copenhagen in 1884 to the gentlemen who conveyed the invitation that the next meeting should be held in the United States of America.

I believe that it has never been considered that the members at one Congress should give any formal authority for any part of the organization of the next. At each meeting some place has been named at which it was deemed desirable that the next should be held; and at the same time, or soon afterwards, some persons of high repute in that place have been asked to take such steps as they might deem necessary or most likely to promote a successful meeting.

Thus, after the Congress at Amsterdam, in 1879, the President, Professor Donders, wrote, in the first instance to Sir Joseph Lister and Sir William Bowman, and by them, and those whom they asked to act with them, the first and all the principal subsequent measures were adopted for the promotion of the meeting in London. Sir Risdon Bennett, the Chairman of the Executive Committee, communicated to Professor Hannover and Professor Panum, of Copenhagen, the desire that the next meeting might be in one of the chief cities of Scandinavia; and those gentlemen, and others acting with them, began and had the principal part in all the arrangements for the Congress in Copenhagen.

I fully believe that it was understood at Copenhagen that the same course would be pursued in the organization of the Congress to be held at Washington. I was at the General Meeting at which, after some discussion, the majority of the members present expressed the wish that the next Congress should be in the United States; and I have no doubt that it was expected that the distinguished American gentlemen there present would obtain the coöperation of the most eminent of their professional brethren, and would, with them, make all the arrangements which they should deem best.

Certainly it was not supposed that the Congress would be regulated, with any degree of exclusiveness, by the members of one medical association, however numerous; and I think it quite as certain that, if this had been thought possible, the proposal that the next meeting should be held in the United States would not have been adopted.

I am sorry, also, to feel sure that if the Congress be not supported by the eminent men who have now declared that they will take no part in it, the members of the profession in this country who will attend it will be very few. And in this opinion, as well as in all that I have written here, I have the concurrence of several of the most influential of the London Congress with whom, before this writing, I consulted.

Believe me, dear Dr. Hays,

Most truly yours,

JAMES PAGET.

POISONING WITH CANNABIS INDICA, WITH RECOVERY.

To the Editor of THE MEDICAL NEWS.

SIR: In *The Medical Record* of July 11, 1885, Dr. Thomas W. Lauterborn, of Newark, N. J., records "A Case of Poisoning by Cannabis Indica, with Recovery." As the symptoms in these cases are at least alarming to the family, I submit a brief account of a case which came under my observation:

For some time, like "Ludlow," I had been taking the drug to note cerebral effects. A friend of mine, Mr. X., volunteered to be a subject, that I might record physiological symptoms. By mistake, he swallowed pills which represented over thirty grains of ext. cannabis indica. I was unconscious of the error until about one and a half hours afterward, when my friend had entered the stage of excitement, and spoke of dual consciousness, etc. I had previously used emetics upon myself without avail, so gave Mr. X. about two ounces of lime juice. Within ten minutes the symptoms subsided. He was soon himself again; complained only of drowsiness and a heavy feeling in the head. Retired, slept soundly, went to business next morning, "feeling none the worse," as he said, "for last night's dissipation."

On discovering the error I felt the need of giving an antidote, as twenty grains of the same extract previously produced, in my own case, after the stage of excitement, thirty-six hours of deep sleep. I have used lime juice on myself to prevent the drug entirely controlling my will.

Prof. Alfred Stillé mentions the antidotal effects of lime and lemon juice in the United States Dispensatory under the head of Cannabis Indica.

Very respectfully,

J. ALBAN KITE, M.D.

NANTUCKET, MASS., AUG. 2, 1885.

NEWS ITEMS.

NEPHRECTOMY AND NEPHROLITHOTOMY.—On July 25th, MR. KNOWSLEY THORNTON performed abdominal nephrectomy for cystic kidney at the Samaritan Free Hospital. The patient, aged twenty-two, had been under the care of Mr. Manley Sims. A drainage-tube was inserted into the loin, and removed on the second day; the patient is now convalescent. On July 27th, the same operator removed a smooth calculus, weighing two ounces, from the left kidney of a young woman who had been under the care of Dr. George Johnson. The case was supposed to be an instance of strumous kidney in its earliest stage, and the operation was commenced as in abdominal nephrectomy; but, as soon as the kidney could be touched, it was found to contain a stone, and strong adhesions prevented its removal. The calculus was, therefore, extracted, and a glass tube placed in the abdominal, and an India-rubber tube into the lumbar, incision.—*Brit. Med. Journal*, Aug. 1, 1885.

PUBLIC OPINION ON THE CONGRESS ORGANIZATION.—We cannot discuss the merits of this far from edifying quarrel, but we are too greatly interested in the International Medical Congress not to raise our voice in protest against a state of matters which is both a professional scandal and a serious peril to the continued existence of the Congress. Hitherto it has been considered binding upon all participating in the Congress that medical politics shall be entirely excluded from all its proceedings. But apart from that, we must impress upon our American friends the simple consideration that unless the whole profession in the United States combine cordially in the work of the Congress the meeting in Washington is foredoomed to failure. Party spirit is so alien to the whole spirit of the International Congress that a large proportion of those who have previously joined in the meetings would certainly, and with justice, refuse to visit the United States to be the guests of a faction. But we have too high an opinion of our transatlantic friends to believe that this unseemly quarrel, which is disgracing them throughout Europe, will be allowed to continue. We trust that moderating influences will be brought to bear upon both parties, and that, forgetting the past and their own personal predilections, they will cordially unite to promote the success of the meeting in 1887. If, however, the breach now formed is allowed to widen and deepen, it will be the duty of the officers of the Congress in Copenhagen to seek at once an invitation from some country in which the medical profession will not find it impossible to combine for international purposes.—*The Lancet.*

We are not surprised, and must confess being glad, at seeing with what almost unanimous action on the part of the leading members of the profession the result of the Chicago session of the newly appointed Committee has been met. The resignation of nearly every prominent appointee on the full committees and Sections made at that session shows a feeling of dignity and self-respect, and the fact that so many physicians in different parts of the country have expressed their sympathy with that action is plainly indicative of a feeling that something is more than wrong in the position taken by the American Medical Association at its late meeting in New Orleans. The thing to be sorry for is not the fact of these meetings in different cities, and the action there taken by the doctors present, but the fact that all this was made a necessity by the personal ambition of some men who felt that they had been slighted. —*Virginia Medical Monthly.*

It is very well understood that the disturbance at New Orleans was incited by disappointed personal ambitions. The Code and geographical distribution have been used to arouse opposition to the arrangements of the first Committee.—*Boston Medical and Surgical Journal.*

The original committee had done good work in perfecting the necessary arrangements to make the Washington meeting a successful one; hence, to be confronted with the ostensible condemnation of the American Medical Association, led and controlled at New Orleans by a few men of doubtful honesty of purpose, is a burning shame and disgrace. We were in attendance at the New Orleans meeting, and can assure the profession that the sentiment which the meeting seemed to express was not the will of the great majority of the delegates present, but was the secret manipulations of a half-dozen or less, who forced the issue upon the passive and more considerate men, who allowed themselves unwittingly to be imposed upon by the misrepresentations of those who have little if any interest in the welfare of the Association. It is to be hoped, however, that there may yet be a concerted action, and that the Washington meeting, now almost a hopeless failure,

Digitized by Google

may have instilled into it new life. The best that can possibly be done will not now relieve the matter entirely of the odium which the disreputable conduct of the men referred to have heaped upon it.—*Kansas City Medical Record.*

The officers of the Congress, as selected by the New Committee, are very generally refusing to serve; at least such is the case with those from Philadelphia, Boston, Washington, Cincinnati, and Baltimore, while numerous other resignations have come in from other cities. Many of the most important Sections have thus been left without officers. Five of the original Committee of eight have resigned, including Dr. Billings, and the Secretary General has also declined to serve. Matters have, indeed, assumed such a shape that no one, with any self-respect, can afford to take the places thus left vacant; to be a *second choice*, even under the most favorable circumstances, is always sufficiently humiliating, but to consent to be such in the present crisis, would certainly indicate an utter absence of professional pride.

The New Committee are trying to shift the blame, or responsibility, for their action—in throwing *out* all the New Code men, and putting themselves *in*—upon the impersonal shoulders of the American Medical Association. This is the height of unkindness; for the members of this Committee were, most of them, the very persons who led the poor old Association to take the unwise action it did, and their zeal in so doing resulted in their appointment on the Committee; in other words, it is the old story over again of the monkey, the cat, and the chestnuts, only the monkey in the fable was satisfied with the results which he had obtained at the physical expense of the cat, and did not attempt to attach to her any moral obloquy for her compulsory act.

The cry against the "New Code" men was all bosh. It was raised at New Orleans simply to divert attention from the real purpose of those who uttered it, on precisely the same principle as the matador flaunts his red flag in the face of the bull. A few sharp and unscrupulous politicians—who had no claim to recognition in the organization of the Congress, and had hence received none—used that cry as a means of foisting themselves into prominence. They succeeded in their *ruse*, but "vaulting ambition o'erleaped itself," and the Congress, under their management, is hopelessly fated. They have come to a realizing sense of this fact, and, anxious to stand from under, are now wildly endeavoring to make themselves, and others, believe that the blame for the failure must rest on those who have withdrawn! They may deceive themselves by such audacious claims, but surely no one else.—*Columbus Medical Journal.*

REGULATIONS PRESCRIBED BY THE MINISTER OF THE INTERIOR OF RUSSIA, FOR THE SANITARY CONTROL AND SYSTEMATIC DISINFECTION OF VESSELS ARRIVING FROM COUNTRIES AFFLICTED WITH CHOLERA.—1. All vessels arriving from countries afflicted with cholera are subject to the "observation" prescribed by the Ministry, for fourteen days, in the quarantine harbor.

2. The time of the observation is reckoned from the date of the placing on board of the quarantine guard.

3. The observation consists in keeping the vessel, her crew, passengers, supplies, and cargo under the supervision of the quarantine authorities, and without any communication with other vessels, people, or the shores, until her admission to traffic is found to be perfectly safe.

4. If, upon an examination by the quarantine authorities of the crew and passengers, and an inspection of the vessel and cargo, the master, holding a "clean bill of health," signifies his consent to undertake, at his expense, and under the direction and supervision of the quarantine authorities, the proper systematic disinfection of the vessel, then the observation terminates in seven days, including the time necessary for putting the vessel into proper sanitary condition.

5. The systematic disinfection must be applied to: rags of every description, bedding and clothing (particularly those having been in use, and remaining soiled), excreta of animals, offal of every description, and particularly of animal and vegetable origin, hides, hair, bristles, feathers, wool, felt, and the like; the rooms and spaces occupied by the crew and passengers, and the above enumerated things; the hold of the vessel, and all the persons, without any exception, on board the vessel.

6. The systematic disinfection consists in the following: Offal of every description, and all soiled articles capable of holding the contagious principle of cholera, which are of no value, or which cannot be disinfected, are subject to immediate destruction by burning, or sinking into the sea.

7. Bedding and underclothing, and similar articles, must be washed in either boiling water or boiling lees, and then thoroughly dried and aired in open air.

8. All the berths of the crew, and cabins of the passengers, and all the articles of furniture therein, and all the space occupied by so much of the cargo as is subject to disinfection, must be thoroughly cleansed by means of brushing, scrubbing, and washing with boiling water, and subsequent drying and airing.

9. The hold of the vessel must be disinfected in the following manner: the hold is connected by means of a length of hose with the forcing arm of a pump, a stream of sea water is poured on each part to be washed, which must be preliminarily scraped and scrubbed; the washing can be considered as sufficient only at the moment when the water pumped out of the hold is as clean as that last pumped in, whereupon all the compartments of the hold are to be abundantly and protractedly aired, using, if necessary, an air pump. Sailing vessels, which have no steam pumps of their own, may use the pumps of steam tugs and other similar vessels in port.

10. All the persons on board must wash themselves with green soap (take a common bath) and put on disinfected clothing.

11. Vessels with foul bills in regard to cholera, and also vessels assimilated thereto, are indispensably subject, besides the systematic disinfection, to measures of quarantine disinfection.

12. For quarantine disinfection the following means must be used: 1, an aqueous solution of carbolic acid (1 : 18); 2, an aqueous solution of bichloride of mercury (1 : 1000) and 3, aqueous vapor at a temperature of not less than 100° C.

13. All articles enumerated in section 7, when on board of vessels with foul cholera bills, must be disinfected by means of carbolic acid or hot vapor. The

Digitized by Google

articles must be either submerged for forty-eight hours in the carbolic acid solution (1 : 18), or be subjected to the action of hot vapor having a temperature of not less than 100° C. The vapor is introduced into the spaces occupied by the articles for a length of time proportioned to the nature of the articles, and other circumstances: for objects easily permeable, not less than one hour; for less permeable objects, two hours at the least. The time will be reckoned from the moment when the temperature of the vapor coming out of the room operated upon will have reached 100° C. Upon the completion of the processes of disinfection, the articles subjected thereto must be washed, dried, and aired in the manner described in section 7.

14. On vessels with unclean bills, the rooms specified in section 8 must be disinfected by means of carbolic acid solution (1 : 18), the ceilings, walls, floors, and other parts and objects are to be scrubbed with mops or rags soaked in the solution, or else the rooms must be subjected to the action of hot vapor, as described in section 13.

15. The disinfection of the hold and its contents is to be effected by means of corrosive sublimate, according to the greater or less quantity of water accumulated in the hold, allowing one pound of sublimate for each thousand pounds of water in the hold; 1¼ to 2½ pounds of sublimate are to be dissolved in a wooden vessel, in 25 to 50 pounds of water. A complete solution, with the assistance of constant stirring, will require about two hours. This solution is poured into the water in the hold, and is carefully mixed therewith by stirring for at least an hour. Each separate compartment of the hold must be thus disinfected. Such compartments in a hold as are connected by hatches may, upon the opening of the hatches and the establishment of a thorough communication between them, be included in one operation.

In order to ascertain whether this disinfection is equal to its object, the following test is to be made: Take samples of the disinfecting fluid from various parts of the hold, dip into them the ends of strips of copper made clean by rubbing with polishing paper, or by sulphuric acid, and see whether, upon remaining for two minutes in the liquid, and being taken out, the ends of the strips are covered with a distinct gray film, which may be easily rubbed off. If no such film appears, the disinfection must be held to be unsatisfactory, and must be continued by fresh additions of sublimate solution, and stirring of the water in the hold, until it yields the indicated reaction upon the copper strip. After the saturation of the water in the hold, as above described, it must be left to stand for twenty-four hours. After it has stood in the hold for at least twenty-four hours, the disinfected water must be pumped out, and sea-water pumped in, in a quantity equal to that pumped out. In order to remove the disinfectant as thoroughly as possible, the hold must be filled with sea-water and emptied, alternately, at least three times within the succeeding three days.

A COMPARISON BETWEEN THE BRITISH AND THE AMERICAN MEDICAL ASSOCIATION.—*The London Medical Times*, in an editorial upon the late meeting of the British Medical Association, says: "It must be admitted that, except for occasional lapses, both the Association and the journal which forms its *raison d'être* have been conducted with a discretion amounting almost to genius. The lamentable muddle into which the sister Association in the United States has thrown the medical profession in that country, has come upon us as a revelation, to make us grateful for the policy which has kept our own Association free, on the whole, from the machinations of self-seeking wire-pullers, and has kept a sufficient place of honor for the scientific leaders of the profession. Reading of what has recently happened across the Atlantic, we ought to be thankful that the powers of our own Association have not been abused, as they might have been, to the forcing upon us of leaders whose only claim to leadership is skill in the lobby."

UNIVERSITY OF VERMONT.—Dr. Leroy M. Bingham, of Burlington, Vt., has been appointed Professor of Surgery in the University of Vermont, to succeed the late Dr. J. L. Little, of New York.

DR. GIOVANNI BATTISTA SORESINA, founder of the *Giornale Italiano delle malattie Veneree e delle Pelle*, died recently at the advanced age of eighty-two.

PROF. VOLKMANN.—The honor of nobility has been conferred on Dr. Richard Volkmann, Professor of Surgery in the University of Halle.

DR. LAZAREWITCH, the eminent Professor of Obstetrics and Gynecology in the University of Kharhoff, having occupied the Chair for the full legal term, has been appointed Emeritus Professor.

PROFESSOR MILNE-EDWARDS.—The death, at Paris, of this eminent professor, at the advanced age of eighty-five, is just announced. He was born, of English parentage, at Bruges, in 1800, and studied medicine at Paris. In 1841, he was elected Professor at the Jardin des Plantes, eventually succeeding Geoffrey St. Hilaire. He was a Grand Officer of the Legion of Honor. His services to science are well known, and his most important contributions are contained in the twelve volumes of his *Leçons sur la Physiologie et l'Anatomie Comparée de l'Homme et des Animaux* (1857–1877).

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 4 TO AUGUST 10, 1885.

J. M. BROWN, *Surgeon*, CLARENCE EWEN, A. W. TAYLOR, *Assistant Surgeons*.—Ordered to rejoin their proper stations in the Department of the Platte.—*A. G. O., No. 7, Division of the Missouri*, August 1, 1885.

G. L. EDIE, and C. S. BLACK, *Assistant Surgeons*.—Ordered to rejoin their proper stations in the Department of Texas.—*A. G. O., No. 7, Department of the Missouri*, August 1, 1885.

WILLIAM D. DIETZ, *First Lieutenant and Assistant Surgeon*.—Ordered from Fort Selden to Fort Stanton, N. M.—*S. O. 111, Department of the Missouri*, July 31, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

ORIGINAL LECTURES.

SOME FORMS OF MYELITIS, THEIR DIAGNOSIS FROM EACH OTHER AND FROM HYSTERICAL PARAPLEGIA.

Two Clinical Lectures delivered at the Philadelphia Hospital.

BY CHARLES K. MILLS, M.D.,

NEUROLOGIST TO THE PHILADELPHIA HOSPITAL; PROFESSOR OF DISEASES OF THE MIND AND NERVOUS SYSTEM IN THE PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE, ETC.

(Reported by William H. Morrison, M.D.)

LECTURE II.

GENTLEMEN: When we last met I considered myelitis in general, and presented to you cases both of diffused myelitis and subacute generalized myelitis of the anterior horns, particularly dwelling upon the latter disease. I shall now discuss (with Case 2 of last week's lecture again before us):

1. The diagnosis of subacute or chronic generalized myelitis of the anterior horns (poliomyelitis, anterior subacute or chronic) from some other forms of myelitis and from spinal congestion.

2. The diagnosis of subacute or chronic generalized myelitis of the anterior horns from hysterical paraplegia.

3. The diagnosis of hysterical paraplegia from forms of spinal disease other than subacute or chronic myelitis of the anterior horns.

Acute anterior poliomyelitis, better known as spinal infantile paralysis, or the essential paralysis of children, and also sometimes spoken of as the acute atrophic spinal paralysis of children, is a disease which has now been long described, and is quite thoroughly understood. Most educated physicians would recognize it without trouble. A disease essentially the same occurs, but much more rarely, in the adult—the acute spinal paralysis of adults. In either of these forms of disease, after an acute onset, with fever, and sometimes with diarrhœa, vomiting, twitching, tremors, and even convulsions, marked paralysis of variable distribution, but usually of a few muscles or groups of muscles, is rapidly developed. Some improvement of the paralysis nearly always takes place, but complete restoration is not common. The muscles which remain paralyzed become flaccid, rapidly atrophy, become cold and dusky, show the reactions of degeneration, and in unfavorable cases eventually cease altogether to respond to electricity. Both the skin and tendon reflexes are much impaired or absolutely abolished; there is arrest of development of the bones; and striking deformities of the joints and limbs often occur. In the adult the disease differs from the affection as seen in children mainly in the fact that the trophic changes and deformities are not so decided in the former because of the fuller development of the bones, joints, and ligaments involved. This is a rapid sketch of the infantile paralysis, already, no doubt, familiar to most of you.

The case before you last week and again to-day, and the one whose history I read at the last lecture, differ from cases of these familiar types, in that the cases of subacute or chronic generalized myelitis of the anterior horns occur usually in adults, and rarely in children; they are more general and more uniformly bilateral in their manifestations; the paralysis extends from point to point, usually from below upwards; and, finally, in that the tendency to complete recovery is greater. (Bramwell's *Diseases of the Spinal Cord.*)

In order to diagnosticate subacute myelitis of the anterior horns from *diffused myelitis*, acute or chronic, a careful study of the symptoms is all that is necessary. In diffused myelitis, as in the case of arsenical paralysis which I have shown, you have not only paralysis, absence of reflexes, trophic changes, and the reactions of degeneration, which are present in the woman before us, but, in addition, well-marked disturbances of sensation; because, in diffused myelitis, there is involvement of all parts of the cord, the sensory as well as the motor and trophic regions being affected. If this woman, in addition to her motor, trophic, vaso-motor, and reflex phenomena, also presented certain sensory phenomena, as anæsthesia, more or less complete, the probabilities would be in favor of diffused myelitis. I believe that in many of these cases of widely distributed anterior poliomyelitis the myelitis is more or less diffused in the beginning, but the brunt of the inflammation is borne by the anterior horns while the rest of the cord rapidly clears up.

Landry's paralysis, or acute ascending paralysis, is similar in some of its features to subacute generalized anterior poliomyelitis, and by some the two are regarded as identical. Westphal, quoted by Seguin in his monograph on *Poliomyelitis*, gives the following points of difference: In Landry's paralysis, asphyxia is frequent, the muscles do not lose their faradic contractility. It usually develops suddenly, the patient first noticing muscular weakness, which rapidly deepens into complete paralysis. The paralysis most commonly begins first in the legs, and within a few hours or days becomes absolute. Weakness in the arms is then noticed, and this deepens into paralysis. Then swallowing and respiration become affected, and the patient often dies, commonly in from three or four to fifteen or twenty days, the average duration being from eight to twelve days. The pathology of the disease is obscure. One point in which it is said to differ from subacute inflammation of the anterior horns is in that, although the paralysis is so complete and leads so quickly to death, there are in most cases no reactions of degeneration. In Landry's paralysis, again, as a rule, there is no sensory disturbance, and the bladder and bowels are not involved, nor are the muscles much atrophied. It has a typical, peculiar, rapidly ascending course, which leads often but not always to death. Some time ago I saw a

Digitized by Google

young lady die of this affection, much to the surprise of her physician, who had supposed that she was suffering from hysterical paralysis.

Hæmatomyelitis sometimes simulates subacute anterior poliomyelitis. A striking peculiarity of hæmatomyelitis is the sudden paralysis, which may develop even more rapidly than in true Landry's paralysis, even in a few minutes. It usually first appears in the legs, then the arms are affected, with pain in the back, and other sensory symptoms. The differences between it and Landry's paralysis are in the very sudden onset, and prominent symptoms of irritation. The following are the notes of a case of this kind, with post-mortem, observed in this hospital:

Case 4.—J. R., colored, aged 60, was brought to the hospital with the statement that he had suddenly a stroke of paralysis eight days previous, since which time he had been getting worse. When admitted he was sinking rapidly, the breathing was short and labored, heart's action feeble and irregular, pulse 104, feeble, and occasionally intermitting. He could not protrude the tongue beyond the lips, and swallowed with difficulty, the act being accompanied with a choking sensation, and the ejection of frothy mucus. He spoke with great difficulty, and complained of sharp pain in the back, between the shoulders and up and down the spine. He had no headache. The bowels had not been opened, but the urine was passed involuntarily. He had a moderate amount of power in his arms. The legs were stiff and motionless. The right axillary temperature was 102°; the left 102.5° F. Every few minutes there was a spasmodic jerking of the legs and body, but no trismus. An autopsy showed minute hemorrhages throughout the gray matter of a softened cord.

Another trouble which often closely resembles the affection under discussion is *spinal congestion*. The patients come with a history that after exposure they have lost the use of their lower limbs, and sometimes of the upper. Heaviness and pain in the back are complained of, and also more or less pain from lying on the back. Numbness in the legs and other disturbance of sensation are also present. The electrical reactions are changed only to a slight extent, if at all. The paralysis may be almost altogether complete. Such patients exhibit evidences of the involvement of the whole cord, but not a complete *destructive* involvement. I am able to show you a case, which this very day leaves the hospital cured. The following is her history:

Case 5.—L. P., colored, age unknown, had been in her ordinary health until November 24, 1884. At this time, while washing, she noticed swelling of the feet which soon became painful, finally associated with loss of power. She had also a girdling sensation about the abdomen, and a pain in the back. She was admitted to the hospital one week later, at which time there was retention of feces and urine. She had some soreness and tenderness in the epigastrium. She complained of dyspnœa which was apparently independent of any pulmonary trouble. It was necessary to use the catheter for one week, by which time control of the bladder had been regained. The bowels were regulated by purgatives. She was given large doses of ergot and bromide and iodide of potassium, and slowly improved, and after a time was able to get out of bed and walk with the aid of a chair. An examination at this time showed that the girdling pain had disappeared. There was distinct loss of sensation. Testing the farado-contractility, it was found that in the right leg, the flexors only responded to the slowly interrupted current, while in the left both flexors and extensors responded to the interrupted current. In both limbs with the galvanic current, the flexors responded to twenty cells, while the extensors responded to fifty cells. She gradually improved, chiefly under electricity, and is now able to leave, having been in the hospital three months.

Let us now turn to the question of the diagnosis of subacute myelitis of the anterior horns from hysterical paraplegia.

"A young woman," says Bennett,[1] "suddenly or gradually becomes paralyzed in the lower extremities. This may, in a few days, weeks, or months, in different cases, become complete, or may remain partial. There is no loss of sensation, no muscular rigidity, no cerebral disturbances, nor any affection of the bladder or rectum. The patient's general health may be robust, or it may be delicate. She may be of emotional and hysterical temperament, or, on the contrary, of a calm and well-balanced disposition. At first, there is no muscular wasting, but, as the disease becomes chronic, the limbs may or may not diminish in size. The entire extremity may be affected or only certain groups of muscles. Finally the disease may partially or entirely recover, or may remain almost unchanged for years."

Two facts are often overlooked in this connection, first, that poliomyelitis is just as liable to occur in the hysterical as in any other class; and, secondly, that the symptoms of hysterical paraplegia and poliomyelitis may go hand in hand.

Following the proper clinical method, let me next show you this case of hysterical paraplegia.

Case 6.—This patient has been in this hospital for a number of years. I saw her for the first time, eight years ago, at which time she was more helpless than she is at present. For a time she was in another hospital; this was two years before I saw her. While there she regained the use of her limbs, and left the hospital walking. This power had been lost when she came to this hospital, but in the course of a few months she regained the use of the limbs, and was able to walk again. This did not continue and she again relapsed. In other words, we have a history of complete or almost complete paralysis of the lower limbs with several recoveries and several recurrences of the helpless condition. As you can see, she has a certain amount of power in the muscles of the lower extremity, but this is not marked, and she states that she has no feeling in the legs. The patellar reflex is well preserved, or if anything exaggerated. There is even a little clonus. The arms are not affected, and she has no trouble with the bladder or bowels, nor has there been any affection of the voice. In spite of the long disuse of the legs, they are still well preserved. Testing next as to farado-contractility, we find it well preserved, and finding this, it is, as a rule, not necessary to employ the galvanic current, as galvano-contractility is usually present under these circumstances.

We have in these two young women the points of differential diagnosis between subacute or chronic mye-

[1] Lancet, vol. ii. p. 842, November, 1882.

Digitized by Google

litis of the anterior horns and hysterical paraplegia. In diagnosticating hysterical paraplegia from diffused myelitis, we would be governed practically by the same points. The history is somewhat different. In the hysterical case, there is a history of at least two occasions on which she recovered the use of the limbs for a long period. In the other case, paralysis has been present from a definite time until the present. This history of frequent attacks of paralysis, in connection with other hysterical symptoms, is very suggestive although not always positive.

The patellar reflex is retained, often exaggerated, and rarely lost in hysteria, while it is usually lost in poliomyelitis. Electro-muscular contractility is often normal in hysterical paralysis; although sometimes it is slightly diminished quantitatively to both faradism and galvanism. The various muscles of one limb respond about equally to electricity. There are no reactions of degeneration in hysterical paralysis as in poliomyelitis; the cutaneous plantar reflex is impaired; bed-sores are usually absent, as are always acute trophic eschars, and the nail-markings present both in generalized subacute myelitis and diffused myelitis. True muscular atrophy is also wanting in hysterical paraplegia, although the limbs may be lean or wasted from the original thinness of the patient or from disuse. The temperature of the limbs is usually good. There is no blueness nor redness of the limbs, nor are the bowels and bladder uncomfortably affected. In the case of poliomyelitis the disease came on with diarrhœa and fever; often also it comes with vomiting and with pain. The paralysis first affected the leg, and then progressing affected the arms.

This case of hysterical paraplegia might possibly be considered as one of spasmodic tabes or spastic spinal paralysis, of remarkably slow progress. It is often difficult to distinguish between the two. Hughes Bennett, and Muller, of Gratz, call attention to the fact that young women may exhibit all the signs of primary spastic paralysis, simulating sclerosis, and yet recover.[1] If I did not know the long-continued history, I might think it was possible that this was a case of lateral sclerosis, and it may be that real degenerative disease of the cord has gradually occurred in this patient, but I know that she has been on her feet on two occasions after having been completely paralyzed. If, however, a recent case of this kind came to you, you can see how difficult it might be to distinguish the two affections, and you would have to fall back on a few things to make the diagnosis.

Spondylitis, or caries of the vertebræ, is sometimes difficult to distinguish from hysterical paraplegia, or hysterical paraplegia from it, or you may have both in the same case. Likewise, painful paraplegia from cancer or sarcoma of the vertebræ may present some difficulties.

Case 7.—We have here a case of which the following is a short account: L. K., aged 44, when two years old met with a fall which was followed by disease of the spine, and has resulted in the characteristic deformity of Pott's disease. She was apparently well able to do ordinary work until five years ago, when her legs began to feel numb and heavy, and with this were some pain and some slight loss of power. These symptoms increased, and in three months were followed by a total loss of power in the lower extremities. She was admitted to this hospital some four years ago. From the time of entrance until about one year ago, she was unable to move the legs. She went around the wards in a wheeled chair. The diagnosis was made of spondylitis, curvature, and paralysis and sensory disorders depending on compression myelitis, and it was supposed for some time that she was beyond the influence of remedies. One day one of the resident physicians gave her a simple digestant or carminative, soon after which she got up and walked, and has been walking ever since. She attributes her cure entirely to this medicine.

What is the lesson to be learned from this case? It is, in the first place, not to consider a patient doomed until you have made a careful examination. There can be much incurvation of the spine without sufficient compression to cause complete paralysis. In this patient we have an organic associated with a hysterical condition. This woman had disease of the vertebræ, the active symptoms of which had subsided. The vertebral column had assumed a certain shape, and the cord had adjusted itself to this new position, yet for a long time she was considered incurable from the fact that the conjunction of a real and a hysterical or mimetic disorder was overlooked.

Case 8.—Two years ago I was consulted by letter about an unmarried woman, aged 27, the youngest of eight or nine healthy children, whose parents were living at an advanced age. The patient had whooping-cough, which lasted six weeks, and was followed by severe pain in the back. For this she consulted various physicians, being treated for Pott's disease and spinal irritation. She, however, continued to grow worse, and every jar and twist gave severe pain. At this time she had lost much flesh, had pain in the back and elsewhere, and was subject to numerous and violent "spasms." She was now treated by a local practitioner, and improved to a certain extent. When first seen by the physician who consulted me, she was complaining of pains in her legs, hips, and left shoulder, which she considered rheumatic, and with pain in the abdomen.

Examination of the back with the patient on her side showed a slight prominence over the position of the first or second lumbar vertebra. This spot was painful on pressure, and had been so ever since the attack of whooping-cough three years before. She stated that every movement of the spinal column caused pain. At times the pain has been so severe that she could scarcely tolerate anyone walking across the floor of the room. A tap on the sole of either foot made her complain of severe pain in the back. The same result followed pressure on the head. The patient was unable to stand or walk, but occasionally sat up for a short time, although suffering all the time. *There was no muscular rigidity.*

The limbs and body were quite thin, but so far as could be detected she had no loss of motor or sensory power. At times when the rheumatic pains were worse the arms would be flexed involuntarily, and she stated that once the spine was drawn back and a little sideways. The pain in the hips was augmented by pressure. The appetite was rather poor. The doctor, supposing that she was suffering with spondylitis, advised the application of a plaster bandage, to which, after much entreaty

[1] Quoted by Althaus. On Sclerosis of the Spinal Cord, by Julius Althaus, M.D., M.R.C.P., etc. G. P. Putnam's Sons, New York, 1885, p. 330.

Digitized by Google

on the part of the parents and friends, the patient consented. During the application, however, she had a sort of fit and fainted, and the application was suspended. She soon recovered consciousness, but refused to allow the completion of the dressing. I gave the diagnosis that the affection was largely hysterical, and a few months later received word that the patient was on her feet and well.

The association of hysteria with real and very severe spinal traumatism partially misled me in the following case:

Case 9.—A middle-aged man had been injured in a runaway accident. He sustained a fracture of one of the upper dorsal vertebræ, probably of the spines or posterior arch. This was followed by paralysis, atrophy of the muscles, contractures, changed reactions, bladder symptoms, and bedsores. There was also anæsthesia, and the upper extremities were affected. Marked mental changes were present, the man being almost insanely hysterical.

The diagnosis was fracture followed by compression myelitis, with descending motor and ascending sensory degeneration. An unfavorable prognosis was given. He left the hospital and went to another, and finally went home. There, I have been told, he was treated with a faradic battery by a woman. He gradually improved and is now on his feet, although not well. In this case there was organic disease, and also much hysteria.

Mistakes in diagnosis where hysteria is in question are frequently due to the association with it of serious organic disease of the nervous system. This is a fact which has not been overlooked by authors and teachers, but one on which sufficient stress has not yet been laid, and one which is not always kept in mind by the practitioner.

Bramwell[1] says: "Cases are every now and again met with in which serious organic disease (myelitis, and poliomyelitis, anterior, acute, for example) is said to be hysterical. Mistakes of this description are often due to the fact that serious organic disease is frequently associated with the general symptoms and signs of hysteria; it is, in fact, essential to remember that all cases of paraplegia occurring in hysterical patients are not necessarily functional—*i. e.*, hysterical; the presence of hysteria, or a history of hysterical fits, is only corroborative evidence, and the (positive) diagnosis of hysterical paraplegia should never be given unless the observer has, after the most careful examination, failed to detect the signs and symptoms of organic disease."

THE EXTERNAL THERAPEUTICS OF PULMONARY CONSUMPTION.

BY THOMAS J. MAYS, M.D.,
OF PHILADELPHIA.

THIRD PAPER.[2]

EXTERNAL applications in the treatment of acute inflammatory diseases of the respiratory organs are so common that it almost seems paradoxical to find them so rarely employed in the more chronic affections of these structures. Their absence is especially and notably conspicuous in the prevailing treatment of pulmonary consumption. Why this is so, is hardly comprehensible, unless it is due to the fact that the dominant sentiment of the profession indorses the doctrines of Laennec, of Charcot, and of other prominent men of the present day (notwithstanding the teachings of Virchow, Niemeyer, and Hamilton to the contrary), that consolidation, crepitation, bronchial respiration, etc., in the apex necessarily means an infiltration of that part of the lung with tubercle. This being the presumed condition, and the rebelliousness and obstinacy of tubercle to treatment taken into consideration, it naturally follows that the course of therapeutics assumes a *laissez faire* character, and the patient is generally advised to emigrate to some more congenial climate, and there his vital resources, unaided by artificial means, are left to struggle against a most desperate enemy, and in the majority of instances he is bound to go down in the unequal encounter.

In this paper I hope to adduce evidence to show that pulmonary consumption, in by far the largest number of cases, is of an inflammatory character; that tubercle is always a secondary product of inflammation; that in most cases a long period elapses between the advent of inflammation in the lungs, and the appearance of tubercle; and that this pretubercular stage can be successfully treated by the proper therapeutic measures.

In order to accomplish this properly we must trace the origin and evolution of the pathological history of a case of pulmonary consumption, and this of course necessitates a brief review of the anatomy and physiology of the lungs, especially that of their vesicular structure. The lungs are essentially composed of bronchial tubes, alveoli, bloodvessels, nerves, and lymphatics. The bronchi are lined with ciliated columnar epithelium, underneath which come in their order the basement membrane, inner fibrous coat, muscular layer, and the outer fibrous coat. The vesicles are merely terminal expansions of the bronchioles, the walls of which are composed principally (1) of elastic and white fibrous tissue, (2) an abundant plexus of capillary bloodvessels, (3) a system of plasmatic spaces, which communicate with the lymphatic vessels of the interlobular septa of the arteries, of the bronchi, and of the deep layer of the pleura, (4) a lining of the alveolar surface consisting of a single layer of flat epithelial cells, and which are by some histologists believed to be endothelial in character, and (5) small valve-like orifices or stomata located between these epithelial cells, and which are in close communication with the plasmatic or lymphatic spaces beneath. These stomata in connection with the lymphatic vessels play such an important rôle in the history of consumption, that their consideration cannot be overlooked. For even in the healthy state it is through them that carbon particles are absorbed from the alveoli and are disseminated throughout the lung by means of the lymphatics.

Now, pulmonary consumption generally begins in

[1] Diseases of the Spinal Cord, by Byrom Bramwell, M.D., F.R.C.P. (Edin.), 1884, p. 301.

[2] My first paper on this subject appeared in the Philadelphia MEDICAL NEWS, March 8, 1884, and the second one in *The Therapeutic Gazette* for June, 1885.

Digitized by Google

the epithelial covering of the alveoli. On account of some irritation they undergo a too rapid proliferation and give rise to an abundant catarrhal excretion, which generally accumulates and fills up the alveoli. The plugging of the alveoli in this manner gives rise to a studded appearance of the part, with nodules of a yellow-grayish color, and which are erroneously called tubercles. They are not tubercles in the technical sense of that term, but merely aggregates of inflammatory products. So far there is nothing histologically involved in the disease process except the epithelial lining and the walls of the alveoli, but the next step originates a different set of phenomena. For the continued proliferation and accumulation of epithelial products in the air-cells must exert a pressure on the capillaries in the walls of the alveoli and in the interlobular septa, and thus seriously interfere with the blood supply and nutrition of the latter. These infiltrated spots are therefore cut off from their source of nourishment, and begin to undergo a retrograde change of caseation—the centre of the spot being furthest from the nutritive supply begins to soften first, and in due time the whole mass breaks down and is expectorated. This is the stage of excavation, and it is here in the pneumonic process that the true tubercle is born.

Either in virtue of a specific poison, or of an accumulation of decaying products, a new element originates here which is absorbed by the lymphatics surrounding the bloodvessels and bronchi, and which incites new nodulated growths in these structures. These are genuine tubercles and differ from those aggregates called yellow tubercles, both in genesis and in structure. They are evolved from interstitial connective or lymphatic tissue, and are growths or a hyperplasia, and not mere accretions like the so-called yellow tubercles. These nodular structures primarily develop in the above named tissue in the alveolar wall and force the surface out into the cavity. By and by the continuity of the wall breaks and the newly formed interstitial connective-tissue cells exude into the alveolar cavity. A number of nodules following such a course will very soon crowd and overdistend the air vesicles, and very naturally these infiltrated areas will be cut off from their blood supply in the same way as those of the catarrhal infiltration are isolated. This is the stage in which the tubercular growth is so liable to be mistaken for the catarrhal infiltration, and *vice versa*. Here the two forms occupy the alveolar cavity, but when minutely examined it is found that one is composed of interstitial connective-tissue growth, and the other chiefly of catarrhal products. From this period the course of the tubercular mass is indistinguishable from that of the catarrhal mass, it softens and is expectorated.

It will thus be seen how important it is to recognize the difference between that stage of pulmonary consumption when it is purely inflammatory, and when it is complicated by the new element of tubercle. Any one who has had even a limited experience with the disease knows full well that in most cases the pretubercular stage is slow in its progress, and that a comparatively long time elapses between the advent of the disease and a break in the continuity of the lung structure. During this stage the patient may be subject to many of the aggravated signs and trying symptoms of the disease; such as dulness, crepitation, subcrepitation, bronchial respiration, constant cough and profuse yellow expectoration, hæmoptysis and blood-streaked sputum, chills and night sweats, loss in weight, want of appetite, etc. Yet it is the most advantageous period for the treatment of the disease—a period in which the patient can be fully restored, but which is often frittered away by doing nothing because of a mistaken notion of the pathology of the disease. After cavitation occurs and tubercle supervenes, the disease undoubtedly assumes a graver aspect, but even then the patient is by no means beyond the reach of medical aid, as some of the cases reported in the first series illustrate.

In order to present the line of difference between the catarrhal and the tubercular element of pulmonary consumption as visibly as possible, I will give a brief comparative outline of their chief characteristics in the following table:

Catarrhal Phthisis.	*Tubercular Phthisis.*
Commences on the surface of the alveolar cavity and in the epithelial layer.	Commences within the alveolar wall and in the interstitial connective or lymphatic tissue.
Is inflammatory in character, and its products consist chiefly of catarrhal epithelial cells.	Is hyperplastic in character, and its products are an increase of interstitial connective tissue elements. First evidence is a small projection on alveolar wall.
Isolated, or groups of alveoli are filled with catarrhal or epithelial products. These accretions are falsely called yellow tubercles.	Isolated, or groups of alveoli are filled up with connective tissue cells which break through the wall. These are true gray tubercles.
Continued accumulation causes isolation of these masses from their blood-supply, and consequently they undergo caseation which is liable to be followed by excavation. It is at this period that catarrhal phthisis generates tubercular phthisis.	Same.

After these introductory remarks on the general pathology of pulmonary consumption it is pertinent to inquire what indications in the line of treatment these considerations point out; or, in other words, what important clew does pathology offer in regard to the treatment of this disease? This is a very essential question, and one that has a most vital bearing on the whole province of rational therapeutics. The earliest stage of the disease which usually comes under the practitioner's care is that of slight consolidation of one apex, associated with a prolonged expiratory sound, and bronchial respiration with or without crepitation. This of course indicates a complete or partial infiltration of the alveoli with catarrhal products in that region. It is plain that the indication here is to get rid of these products, and the best method wherewith to accomplish this confronts us here. It is not enough that we only aim to circumvent the local process of inflammation, for it is evident that our attention must also be directed towards the products left behind by the latter process.

Now when we reflect that all portions of the lung are liable to catarrhal infiltration, and that absorption or resolution occurs more readily anywhere else than

Digitized by Google

in the apex, the inference at once strikes us that some close relationship must exist between infiltration and the apex. I do not think that there is any specific affinity between the two; but these products merely remain because there is less circulatory, lymphatic, and respiratory activity in the apex than in any other part of the lung, and hence, less facility for carrying them off. This assumption is further confirmed when coupled with the fact that in mitral disease where there is a constant hyperæmia or fulness of blood in the pulmonary circulation in consequence, catarrhal infiltration, or tuberculization for that matter, is almost entirely unknown. The continual hyperæmia does not allow an opportunity for the accumulation of these products, since they are constantly washed away by the serous transudation present in these cases. It is evident, therefore, that any agent which transfuses a greater degree of activity into the circulatory, lymphatic, and respiratory functions of the lungs will clear up the infiltrated alveoli and bring about a restoration of the apex. Now, in my experience, the external application of moist heat over the apex is certainly one of the agents which possesses the power of promoting resolution and resorption, as I have already shown in my two previous communications on this subject. By stimulating the affected spot and its surroundings with heat, the blood and lymph flow undoubtedly become accelerated, and an increased interchange and absorption of the fluids and solids of the part follow. It is a common remark of the consumptive patient, after being poulticed for a few days or a week, that he feels more free in his lung, and is able to take a deeper breath without pain than formerly.

To make a good poultice, boil the ground flaxseed meal in a sufficient quantity of water to make a thick paste. Spread it quickly in a layer an inch thick between two pieces of flannel cut in the shape of a jacket, which is well fitted to the top, front, and back of apex, as well as to the anterior and posterior aspect of the affected lung. The edges are sewed or tied together, then it is adjusted to the chest, and the outside well covered with oiled silk, or some thick woollen material in order to prevent a too rapid radiation of heat. It must be changed every two or three hours, or sooner if it becomes cooler than the body. This process is to be continued from morning until night, when the poultice is taken off, and the chest is well wrapped with woollen flannel for the night, in order to avoid a sudden disturbance of the bodily temperature during the sleeping hours. The next morning the same programme is begun and continued in the same way for at least three weeks, and so much longer as is necessary. It is much more expedient to poultice during the day only, and allow the patient to rest and be free from the poultice during the night. In fact this is very important, for if you insist to poultice during the night also, you are very apt to worry and discourage the patient, and get him to refuse the application altogether. In a course of five or eight days poulticing, or perhaps sooner, the patient begins to experience relief. The cough becomes easier, and the expectoration more loose. The appetite begins to improve, and the patient coughs less at night and sleeps better. The changes in the physical signs are also at times most marked. Where before the poulticing there was heard nothing but bronchial respiration, subcrepitation and perhaps crepitation, and coarse mucous râles show themselves, leading one to suspect that the disease is advancing instead of receding. In course of time, however, say three weeks, or sooner probably, as will be seen from Case III., the whole part will clear up and become dry.

I will now present the history of a third series of cases of pulmonary consumption, which has been treated by this method, and I think the practical results speak as emphatically in its favor as those of the first and second series of cases.

CASE I. *May 19, 1885.*—W., aged 26, has been sick with severe cough, dyspnœa, pain in the left chest, chills, fever, and night sweats for about two weeks. For the last year and a half the patient has been suffering from chronic bronchitis, and a "fresh cold" brought on the present attack—the disease undoubtedly extending from the bronchi into the alveoli.

Physical examination shows absolute dulness from third intercostal space in front to base of left lung, and from apex of scapula to base behind on same side. Increase of vocal fremitus, bronchial respiration, crepitation and mucous râles distributed over same region. Evening temperature 103.5° Fahr. and pulse 120.

Treatment.—Flaxseed poultice externally, and tincture of iron and quinine internally, together with a nutritious diet.

26th.—Feels very much better. His appetite, which was almost *nil*, greatly improved. Also cough less and easier. Less dulness, absence of crepitation, but mucous râles in abundance. Same treatment.

June 3.—Patient still improving, able to sit up and appetite very good. Temperature normal. Left lung very nearly cleared up as far as râles are concerned. Some dulness still persists. Same treatment.

12th.—Still improving. Râles entirely gone. Some impairment of percussion resonance still remains. Discontinue the poultice.

25th.—Patient very well. Able to walk out for a week past. July 14th, well.

CASE II.—N., aged 35, married, laborer, was seen first April 9, 1885. He complained of cough and pain in right chest for the last year. Has been unable to work lately. Is losing flesh, has yellow expectoration, night sweats, and no appetite.

Physical examination showed dulness in right apex, vocal resonance and fremitus increased over same region. Bronchial respiration over posterior aspect of same apex, and crepitation over anterior aspect. Left lung normal. He was treated variously until May 6th following, when another examination showed no improvement in his physical signs, and his symptoms were decidedly worse. On this day he was ordered to be poulticed over the whole of right lung. On the following 13th of May, his wife reported that he had improved in every respect since he began to poultice—coughs and expectorates less, and is now able to lie on his right side without causing any inconvenience. On the 18th of May, a physical ex-

Digitized by Google

amination showed that the crepitation in apex had almost entirely disappeared. There was also an improvement in the bronchial respiration, and possibly also in the dulness. His cough and expectoration markedly diminished and his appetite very good. He thinks he will be able to go to work very soon. Same treatment.

June 2.—Feels good; crepitation gone and bronchial respiration hardly perceptible; some dulness persists; poultice discontinued.

20th.—Bronchial respiration replaced by a roughened vesicular respiration; very little dulness.

CASE III.—D., aged 35, widow, cook, was first seen May 18, 1885. Had a cough which began two months previously; yellow expectoration; hæmoptysis last March; night sweats; losing flesh; poor appetite; cough very bad at night; bowels and menses regular. She is the only remaining member of a family of eleven children, all the rest having died from consumption or other chest troubles.

Physical Signs.—Dulness in left apex extending to second intercostal space in front, and to spine of scapula behind. Vocal fremitus and resonance increased over same area; crepitation in supraclavicular region; vesiculo-bronchial respiration from clavicle to second rib; defective respiration in posterior apex of same side; puerile respiration in upper portion of right lung.

Treatment.—Flaxseed poultice over left lung, and simple bitters with syrup of squills and senegæ internally.

June 4.—Feels very much better since she began the poultice; cough and expectoration much less and appetite very much improved.

9th.—Gets along well; coughs none at night and expectorates less; night sweats diminished and appetite good. *Physical signs.*—Crepitation in left apex entirely gone, and the dulness as well as vocal resonance and fremitus diminished; discontinued the poultice, otherwise same treatment.

18th.—Continues to improve; physical signs hardly show a trace of disease in left apex; she feels very well, and is able to follow her vocation again.

CASE IV. *June 2, 1885.*—B., aged 24, married; had a steady cough for some time, which is worse at night; yellow expectoration; night sweats; chills and fever; is losing flesh; has no appetite; bowels and menses regular, and heart normal. Physical examination shows dulness in left apex, extending to second intercostal space in front and to spine of scapula behind; prolonged expiration behind, and wavy respiration in front over same area; vocal fremitus and resonance increased here, too; right lung normal.

Treatment.—Internally, tincture of iron and quinia; and externally, flaxseed poultices.

16th.—Coughs less; expectorates the same; night-sweats less, and appetite better; less dulness in apex; vocal resonance and fremitus also less disturbed; wavy respiration disappeared in front. Same treatment continued.

23d.—Cough and expectoration less; appetite good; only occasional chills and night sweats; dulness hardly perceptible in front; poultice discontinued. Same internal treatment.

CASE V.—A., aged 51, stonecutter; was seen first on May 6, 1885, when he complained of constant pain in right side from shoulder to base of thorax, which lodged there a month previously. Pain is of a stitchy character—worse on taking breath; coughs since the attack; has a yellow expectoration, which, at times, is blood-streaked; is losing flesh; appetite poor; no night sweats, but feels very chilly.

Physical Signs.—Dulness on right apex, extending to second intercostal space in front, and to spine of scapula behind; vocal resonance and fremitus increased over this region; also crepitation, which is most marked in supraclavicular region.

Treatment.—Quinia, tincture of iron, and flaxsed poultices to right chest.

June 2d.—Pain and stitch better; coughs less, and has very little expectoration; no blood-streaked sputum since poultices went on; appetite better; but still feels chilly at times.

Physical Signs.—The differences in the vocal resonance and fremitus between the two sides probably less marked; crepitation is gone behind, and replaced by a prolonged expiration and roughened inspiration. Same treatment continued.

9th.—Says he feels much improved since he began the poultices; pain entirely gone out of chest, even on the deepest inspiration; no cough, nor much expectoration; appetite good; no chills any longer.

Physical Signs.—Crepitation vanished, and there is very little difference in the physical signs between the two sides of the chest; stopped the poultice, but continued the quinia and iron.

July 16.—Well, and is going to work.

CASE VI.—M., aged 30; was first seen on June 18, 1885; complained of pain in the right side of her chest; constant cough, day and night; dark greenish expectoration; had hæmoptysis a year ago; night sweats; chills; poor appetite; constipated bowels, and losing flesh.

Physical Signs.—Right side—defective respiratory motion; dulness extending from apex to second intercostal space in front, and to spine of scapula behind; vocal resonance and fremitus increased over this spot, as well as a prolonged expiratory sound, which is especially audible behind over the affected area; left lung and heart normal.

Treatment.—Tincture of iron and quinia, and flaxseed meal poultices externally.

2d.—Feels better; pain nearly gone in chest; coughs very little, only three or four times a day, and not at all during the night, so she states; very little expectoration, but still greenish in color; no more night sweats; occasional chills; appetite good, and bowels more regular; dulness less marked, and vocal resonance and fremitus certainly diminished; prolonged expiration gone behind; stopped the poultices; continued the other treatment.

The deductions which may be drawn in regard to the practical results of the external method of treating pulmonary consumption are, I think, obvious enough, and require no further comment at present. I will reserve for a further paper a review of all the cases so treated which I reported in the three articles on the subject, and there hope to show that the evidence from these examples undoubtedly and decidedly

Digitized by Google

points out the direction in which the successful treatment of this disease lies, viz., in efforts to combat and exterminate the disease by external applications, and to conserve and enhance the resisting power of the body by nutritious food and internal medication.

151 NORTH FIFTEENTH STREET, PHILADELPHIA.

DISINFECTANTS.

PRELIMINARY REPORTS OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

XIV.

THE METALLIC SULPHATES.

BY GEORGE M. STERNBERG, M.D.,
SURGEON U. S. ARMY.

THE metallic sulphates have been largely recommended as "disinfectants," and directions for their use are to be found in the printed circulars of health authorities in this country and in Europe. In France the sulphate of copper is a favorite disinfectant, and, as I shall shortly show, is a reliable agent for the destruction of germs in the absence of spores. It is very much superior to ferric sulphate, or zinc sulphate, which have been more extensively used in our own country.

The value of all these agents as antiseptics is beyond question, and when the object in view is to prevent the development of germs in privy-vaults, cesspools, etc., a solution of "copperas," on account of its cheapness and efficiency, is especially to be recommended. But the directions often given for the use of dilute solutions of ferric sulphate, or zinc sulphate, for the disinfection of the sputa of patients with diphtheria, the excreta of patients with cholera, typhoid fever, etc., are founded upon a mistaken estimate of the germicide power of these salts.

The metallic sulphates have all a certain value for the prevention of putrefactive fermentation, and for neutralization of the volatile products of putrefaction. They are therefore "disinfectants" in the popular acceptation of the term. Thus Vallin says:

"*Metallic sulphates in general.*—These agents are disinfectants in the vulgar sense of the word; they diminish, or cause to disappear, bad odors; their action being limited to the neutralization of ammonia and the decomposition of sulphuretted hydrogen, or of the sulphhydrate of ammonia.

"In this group are the soluble salts of iron, of zinc, of copper, of manganese, and of lead. The oxides of these metals, which are quite cheap, have also been recommended for this purpose; but the salts have the advantage over the oxides of being able to saturate ammonia already formed, or that which results from the decomposition of the sulphhydrate of ammonia; the oxide of iron, for example, can only fix sulphuretted hydrogen by forming the sulphuret of iron; the sulphate of iron produces in addition the sulphate of ammonia.

These salts, then, cannot neutralize all bad odors, and therefore they do not entirely merit the title of deodorants. Bad odors, indeed, owe their infection to a great quantity of diverse substances which have not been completely determined by chemistry, and of which scatol is one of the most recently discovered. It is, then, almost entirely the two badly smelling compounds which have been longest known, which are neutralized by these metallic salts."[1]

"Virchow has pointed out one of the objections to the use of the sulphate of iron for disinfecting feces. The volatile fat acids, butyric, valerianic, etc., which have a disgusting odor and are highly toxic, are ordinarily combined with ammonia. When we throw sulphate of iron upon fecal matter, the sulphuric acid combines with the ammonia and fetid products are given off, which are very volatile.

"The immediate effect, therefore, of throwing sulphate of iron into latrines, is frequently to augment the bad odor, which, however, soon diminishes, but ordinarily reappears after some time." (Op. cit., p. 63.)

In what follows we shall endeavor to fix the value of the metallic sulphates as *disinfectants* in accordance with the definition of the term heretofore given by the Committee on Disinfectants, *i. e.*, the germicide value as fixed by biological tests.

Ferric Sulphate.

In the writer's experiments published in the *American Journal of the Medical Sciences* (April, 1883), it was found that a saturated solution of ferric sulphate failed to destroy the growing power of any of the test organisms, the time of exposure being two hours. A recent experiment upon a micrococcus obtained from the pus of an acute abscess gave a similar result. The organism grew freely in culture solutions, after exposure for two hours to a ten per cent. solution.

According to Arloing, Cornevin, and Thomas, exposure to a twenty per cent. solution for forty-eight hours does not destroy the virus of symptomatic anthrax. The vitality of anthrax spores is not destroyed by exposure for six days in a five per cent. solution (Koch).[2]

Zinc Sulphate.

In the writer's experiments, reported in the *American Journal of the Medical Sciences* (l. c.), a solution of twenty per cent. of this salt failed to destroy the micrococcus of pus. In experiments recently made, the same micrococcus grew after exposure to a ten per cent. solution for the same time (two hours), but development was somewhat retarded. Another micrococcus (*M. tetragenus*) was destroyed by a ten per cent. solution in the same time. Broken-down beef-tea, mixed in equal quantities with a forty per cent. solution, was not sterilized at the end of two hours, as shown by culture experiments made in the usual way.

Koch found (l. c.) that a five per cent. solution had not destroyed the growing power of anthrax spores at the end of ten days, although their development was somewhat retarded.

Cupric Sulphate.

I have recently made experiments with this salt upon pure cultures of *B. anthracis* and of *B. subtilis*, and find that in a twenty per cent. solution (equal parts of a forty per cent. solution and of the culture)

[1] Traité des Désinfectants, p. 57.

[2] See table on p. 264 of the first volume of the Mittheilungen aus dem Kaiserlichen Gesundheitsamte.

Digitized by Google

it fails to destroy the vitality of the spores of these bacilli in two hours' time.

Arloing, Cornevin, and Thomas found that the dried virus of symptomatic anthrax is destroyed in forty-eight hours by a solution of this strength (twenty per cent.). Koch found (l. c.) that a five per cent. solution did not destroy the vitality of anthrax spores at the end of ten days, although the rapidity of development was somewhat retarded.

The germicide power of this salt, is, however, decidedly superior to that of the corresponding salt of iron or of zinc. I have demonstrated by recent experiments that it destroys micrococci in the proportion of 0.5 per cent. (= 1 : 200). The experiments were made upon a micrococcus derived from the pus of an acute abscess, and upon the micrococcus of swine plague. In one-half the amount named (1 : 400) it failed to destroy the vitality of these micrococci.

This agent, then, is a valuable germicide, and may be safely recommended for the disinfection of material not containing spores. But none of the metallic sulphates can be relied upon for the destruction of spore-bearing pathogenic organisms, and the germicidal power of ferric and zinc sulphate is too feeble to make these salts available for disinfecting purposes, even in the absence of spores.

ON THE RELATION BETWEEN THE EARLIEST STAGES OF GRAY DEGENERATION OF THE OPTIC NERVE, AND INCREASE OR DIMINUTION OF THE PATELLAR-TENDON REFLEX (KNEE-JERK).[1]

BY WILLIAM F. NORRIS, M.D.,
CLINICAL PROFESSOR OF OPHTHALMOLOGY, UNIVERSITY OF PENNSYLVANIA.

ALTHOUGH it has long been known that gray degeneration of the optic nerves is at times a forerunner and a herald of similar lesions in the spinal cord, yet the intervals between the recognized times of appearance of the eye symptoms and the spinal symptoms vary so greatly in each case that the frequency of such concurrence has been variously stated by different authors.

It is to the earliest stages of this gray degeneration of the optic nerve to which attention in this paper is directed, where the nerve is simply sickly, and has not yet become atrophic; where there is almost full acuity of central vision, with slight contraction of the fields for form and color, and where the irides are still prompt in their reactions to light and convergence; where, in the beginning, the disk at first sight appears of a general dirty red-gray tint, but, upon a careful focussing, it is found to be superficially capillary, while its deeper layers, especially in the neighborhood of the *lamina cribrosa*, are decidedly gray, and wanting in blood circulation, accompanied by sufficient haze of the retinal fibres to veil the scleral ring. This condition is followed later by a pallid, "filled in," and woolly appearance of the nerve, surrounded upon all sides by a broad, and oftimes sharply cut scleral ring. Such eye symptoms are associations, and not sequences of the spinal disease, and, although they do not give any absolute answer as to the cause, just as any optic neuritis *per se* fails to indicate a definite lesion, yet in this grouping we have a sign of nerve disturbance, which is a true danger signal, and should cause us to look carefully for tabes dorsalis, or other form of degeneration of the central nervous system. The writer does not wish to inculcate that this process of gray degeneration of the optic nerves may not at times be local, and limited exclusively to them, but that in a majority of cases it is a forerunner or an associate of grave changes in other parts of the organism. The ophthalmoscopic appearances, which are the most valuable, should not be confounded with those of the slight retinitis which is so often seen in uncorrected ametropia, or with the more intense form which results from intracranial and orbital trouble, whilst care should be taken to differentiate them from those visible optic nerve changes which often result from faulty nutrition or anæmia, as well as from uterine disease.

Notes of forty-seven cases in the early stage of this degeneration were presented. They showed various degrees of contraction of the fields of vision with often an increase, and more rarely a diminution, in the knee-jerk; the increased patellar-tendon reflex usually corresponding with the larger field, and diminution or abolition of the reflex usually accompanying the smaller field. It was also found that the irides were affected later in the disease, and that the more defective reaction of the iris was in direct ratio with the more degenerate optic nerve. It is very probable that the increased knee-jerk in this early stage is due to irritation of the gray matter of the cord.

Three other cases of gray degeneration of the optic nerves were also detailed, which the writer had been able to follow for several years. In two, gray degenerations of the optic nerves had been succeeded by incomplete atrophy of the optic nerve with gradual diminution of the knee-jerk, lightning pains, ataxic gait, and other well-recognized symptoms of tabes dorsalis. In the third, there were "Argyll-Robertson pupils," failure of accommodation, which, at times, varied in intensity, shooting pains, and ataxic gait.

[1] Abstract of a paper read before the American Ophthalmological Society, July 16, 1885.

SPLINT FOR THE IMMEDIATE DRESSING OF CLUB-FOOT AFTER TENOTOMY, ALSO FRACTURES ABOUT THE ANKLE-JOINT AND LOWER THIRD OF THE LEG.[1]

BY EDWARD DEVELIN, M.D.,
OF NEW YORK.

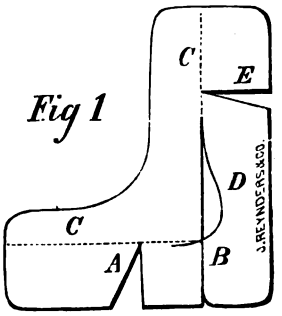
FOR some time past the desirability has occurred to me of having a simply constructed splint, which can be used for the dressing of club-foot immediately after tenotomy. It has seemed to me that one made of tin, carefully padded, which is both firm and light,

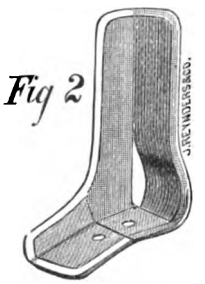
[1] Read before the New York Orthopædic Society.

Digitized by Google

as well as simple in its construction, would fulfil the purpose.

I have, therefore, devised a splint which I here present (Fig. 2), and also show the facility with





which it can be made by any one. It is, as you see, made out of one piece of stout tin (Fig. 1), and reinforced, if necessary, with another small piece underneath, in order to stiffen it.

The advantage of this splint over those made of rubber, felt, plaster of Paris, leather, or foot-board and adhesive straps as sometimes used, is its simplicity of construction, readiness of application by one person, immobility, and the ease with which the foot can be examined at any time without removing it from the splint. It can be made in ten minutes, and in such a manner as to secure eversion or inversion of the foot at the metatarso-junction, as I here show you—the former of course being sometimes necessary after division of the plantar fascia, or short flexors, in talipes varus. In simple equinus this eversion is of course not necessary. Again, in other cases, where the tibialis posticus is somewhat shortened, but not sufficient to warrant an operation, the heel assumes a tendency to turn upward and inward, causing the external malleolus apparently to project. In those cases I make a bend in the splint as you see just above the ankle; so that when the adhesive straps, which fasten the foot in position in the splint, are properly applied, they draw the external malleolus inward, pressing the heel downward, and bring the foot into its normal position.

In order also to draw the anterior part of the foot out and secure a strong eversion after the plantar fascia has been cut, a band of adhesive plaster is passed over the dorsum of the foot to the inner side, and then underneath outward, so that while the heel is held firmly in position, I can evert the anterior part of the foot to a very marked degree, and secure it in this position by passing the adhesive strap under the splint, and then, again, over the top of the foot, in which position it cannot possibly slip.

In applying the splint, after the operation, the foot is at once brought into the normal position, viz., at a right angle with the leg, and then placed carefully in this position in the splint, which is previously well padded. Then draw a band of adhesive plaster over the heel of the splint and across the instep, padding the instep; then take the adhesive plaster at the foot, and, in order to correct any inversion, make traction outward, and secure it as I have just mentioned. I next turn my attention to the leg and upper part of the splint, securing it in like manner with adhesive straps, and the fixation is almost complete. This is extremely simple, for the foot is exposed clearly to view; hence can be seen in almost a moment what will cause, or may be causing, the patient pain, and it can be as quickly relieved without disturbing the condition of the foot, in which it has been secured.

This dressing (Fig. 3) is now supplemented with

an ordinary roller bandage, keeping the parts warm, and giving more firmness and security to the application of the splint.

This is not theoretical, but practical, as I have tested; and, further than this, where the child is so small as to render it difficult to secure a small shoe which will retain its shape, I have allowed the splint to be worn as a shoe, being secured with only a roller bandage, and removed twice daily for the feet to be manipulated and massaged.

Although this splint was designed especially for the treatment of club-foot, it can be used to great advantage in fractures about the ankle-joint or lower third of the leg, either in simple or compound fractures; its cheapness and cleanliness rendering it especially adapted to hospital use.

Fig. 1 shows the piece of tin cut ready to be shaped; C C is the extent of surface placed on the inner side of the leg and foot; A shows V-shaped piece of tin removed to allow of it being bent at the metatarso-junction; E shows V-shaped piece also removed to allow of bending of the splint when the tibialis posticus is contracted as I mentioned. The black line B is simply a direct cut through the tin to allow of it being bent so as to accommodate and form the heel of the splint D. In the majority of cases the V-shaped piece E will not be required to be cut out. If it should require it, then reinforce the back and underpart of the splint after it is formed as in Fig. 2.

Fig. 2 shows the splint complete; the curved piece forming the heel being riveted underneath with two rivets, retains the splint in the desired form, the sharp edges of the tin being simply covered with a strip of ordinary rubber adhesive plaster.

Fig. 3 shows padding and dressing of the foot complete, previous to applying the roller bandage.

This splint can be secured of any size, by giving length of foot and leg, from Messrs. Reynders & Co., 303 Fourth Avenue.

MEDICAL PROGRESS.

IN WHAT CONDITIONS IS DIABETES COMPLICATED WITH GANGRENE?—DR. T. GIRON, in a letter recently addressed to Professor Verneuil, discusses the occurrence of gangrene as found in diabetics. He records the history of sixteen cases, concerning one of which he says: Thus, here is a diabetic in whom the gangrenous process was not developed from a local cause, neither a blow nor a blister, and which presents a series of gangrenous spots—under the influence of an affection of the heart. The influence of diabetes in the production of grangrene, in a patient suffering with heart disease so little advanced, is not doubtful; however, does not their manner and time of appearance, their progress and cure by the use of digitalis, indicate that the condition of the heart plays a most important part in the production of the gangrene, than does diabetes?—*La Progrès Médicale*, July 25, 1885.

INHALATIONS IN PULMONARY TUBERCULOSIS.—During recent times we have heard a great deal of the value of antiseptic inhalations in the treatment of phthisis. A further clinical investigation has been undertaken by DR. RENZI, of Naples. He has employed inhalations of four kinds: First, of iodoform and essence of turpentine, of which two to six drops every hour or two hours of a liquid containing one part of iodoform to twenty-five parts of spirit of turpentine were used; fourteen patients were submitted to this treatment. Secondly, iodine volatilized every day in a bed-room thirty cubic metres in capacity, in the amount of 0.40 to 2.10 grammes, heated in a capsule by means of a sand-bath; three observations were made. Thirdly, sulphuretted hydrogen, evolved by the action of sulphuric acid on powdered sulphide of iron in such proportion that every cubic metre of atmosphere in the chamber should contain seventy-five cubic centimetres; seven cases were thus treated. Lastly, sulphurous acid, made by burning sulphur in a closed chamber, so that there should be forty-three cubic centimetres of the gas in a cubic metre of the atmosphere. Dr. Renzi has found that the first two methods of treatment ameliorate the local condition and general nutrition, without modifying the pyrexia, diarrhœa, or nocturnal sweatings. Inhalations of sulphuretted hydrogen and sulphurous acid seemed to increase the general strength, improving the nutrition and increasing the quantity of urine discharged. Sulphuretted hydrogen had a special influence on the respirations, which were diminished in frequency; it also exercised a beneficial influence on the cough; but the fever, diarrhœa, and diaphoresis were not relieved. Of all the inhalations, the author decides in favor of turpentine and sulphuretted hydrogen.—*Lancet*, July 25, 1885.

TWO CASES OF LAPAROTOMY, IN ONE OF WHICH THE KIDNEY WAS REMOVED, AND IN THE OTHER A RENAL CYST.—At a meeting of the Société de Chirurgie de Paris, held July 22, 1885, M. LUCAS CHAMPIONNIÈRE reported the two following cases of laparotomy:

The first case was that of a young woman who presented a movable tumor in the right side, and which seemed to be in relation with the kidney. Laparotomy was performed, and a renal tumor discovered. In order to remove all possibility of error both kidneys were sought. The left was small and atrophied; the right was situated behind the liver. The tumor was then removed without hesitation, and was lightly attached by a slender pedicle to the convex border of the liver, and was found to be a cyst completely filled with hydatids.

The second case was also that of a woman, who suffered excruciating pains in the right side, which was the seat of a deep-seated tumor. Diagnosis was undecided between suppurative nephritis and perinephritis. The patient passed no pus with the urine; but exploratory puncture in the region of the tumor caused the escape of more than a quart of purulent fluid. M. Championnière then made an exploratory incision and thus reached the kidney. The kidney was found to be very much altered, and the wound was closed, further operation being impossible by the incision made.

A curious fact in connection with the case is, that the patient's urine after the exploratory incision contained, constantly, pus. June 13th, the kidney was removed through an incision made upon the border of the right muscles.

The kidney was first removed and afterward the ureter and fibrous envelope which surrounded the organ. The operation, though difficult, was entirely successful.—*Revue Médicale*, July 25, 1885.

SALICYLIC ACID SUET IN HYPERIDROSIS.—The Berlin correspondent of *The British Medical Journal* writes: All reports of the German army surgeons on experiments recently made with salicylic acid suet, agree in recommending its use as a remedy for extreme sweating of the feet. It is composed of 2 parts of pure salicylic acid to 100 parts of the best mutton suet. The War Minister has, therefore, permitted the introduction of this preparation into the army medical stores, for the benefit of soldiers suffering from sweating feet, or soreness from riding.—*British Med. Journal*, Aug. 1, 1885.

USE OF IODOFORM IN GONORRHŒA.—DR. A. OGER, in discussing the use of iodoform in gonorrhœa, refers to its use in solution of glycerine by M. Campana in acute and chronic conditions of the disease.

The best results are attained, however, when it is applied to the diseased parts in a very fine powder. In this form Timmermans has obtained excellent results. Iodoform being insoluble in water, he suspends, in two and one-half ounces of water, sixty grains of the drug rendered impalpable by previous solution in sulphuric ether. The mixture being well shaken, a small glass syringe is filled and injection practised. As it is important that the iodoform come in direct contact with the inflamed mucous membrane, the urethra should be thoroughly cleansed by urination immediately before the injection is made. The patient should lie on his back and the injection be made in a direction nearly vertical, gravity thus causing the powder to seek the lower part of the syringe, and thus favoring its introduction into the urethra when pressure is made upon the piston. When the syringe has been emptied, it should be gently withdrawn, and while the meatus is compressed by one hand, with the other careful pressure is made so that every part of the passage is reached

Digitized by Google

by the fluid, and the iodoform thus deposited upon the mucous membrane.

After four or five minutes the fluid is permitted to escape gradually, in order to avoid the ejection of the iodoform. The operation should be repeated at least three times a day.

Whatever is the stage of the disease a prompt result is certain, as is shown by diminution of pain—the iodoform evidently acting as an anæsthetic to the inflamed parts.

The character of the pus is also changed, and its abundance diminished. Cure is promptly obtained; in one resulting in five days.—*Journal de Médecine de Paris*, July 19, 1885.

EXCISION OF THE HIP.—DR. WILLIAM ALEXANDER, at the close of an interesting paper upon excision of the hip, thus summarizes his views of this operation:

1. That hip disease should in the earlier stages be treated by that absolute and perfect rest of the joint that we now appreciate so well and know so much better—thanks to Mr. H. O. Thomas—how to apply, without at the same time producing general debility of the system through the restraint and confinement necessary in former times to secure sufficient rest to the joint.

2. That this treatment, thoroughly and persistently carried out for a long period, will cure a very large percentage of cases of joint disease.

3. That unfortunately this treatment *cannot* or *is not* properly or persistently carried out amongst the poor, with whom a persistent attempt to carry it out after a certain stage of the disease has been reached only leads in many cases to a useless limb after many years, and probably in a majority to death, either during the process of cure or soon after, from the exhausting effects of the local disease, and not, as some erroneously think, from an inherited constitutional debility.

4. That many of these patients could be saved by excising the joint when a decided second stage of hip disease has been reached, and that excision is most safely and advantageously performed by severing the femur above the trochanters, clearing out the acetabulum, and maintaining the opposing bones so far apart that their surfaces can resume a healthy condition, and the aperture between become filled up with fibrous tissue. By this means an excellent false joint is formed, or, if the adhesions become too firm, a good stiff joint.

5. That the advent of the stage of the disease suitable for excision is indicated by the repeated formations of abscesses and sinuses round the joint. Then excision, as described, seems to me to offer better results, both locally and generally, than rest and waiting to see what will turn up.

6. That when the supra-trochanteric mode of excision cannot be performed with any chance of success, on account of the extensive nature of the hip disease, the alternative treatment comprises either continued expectancy or amputation, according to the age and condition of the patient.

7. That it is, however, a great mistake to imagine that all softened bone or infiltrated tissue should be cleared away by the operator. All he has got to do is to clear a space where the operations of nature, in dealing with diseased or disabled tissues, can be carried out as easily and expeditiously as possible. The operator should remove all manifes ly dead tissue, but bone and tissue that the surgeon would be inclined to sacrifice as doubtful should be left alone, as these will, under the same skilful hands of nature, be restored to health, or extruded harmlessly if only a passage for their extrusion be maintained.—*The Liverpool Medico-Chirurgical Journal*, July, 1885.

THE RELATIONS BETWEEN THE SYMPTOMS AND THE CORD LESIONS OF POSTERIOR SPINAL SCLEROSIS.—DR. E. C. SPITZKA, in a paper read before the American Neurological Association, June, 1885, in discussing the relations between the symptoms and the cord lesions of posterior spinal sclerosis, says: While it must be admitted that the primary lesion of tabes is competent for each affected level of the root zones and gray horns to produce all the characteristic symptoms of tabes, referrible to that level, yet in the extent and distribution of the consecutive lesions we have valuable gauges of the extent, severity, and duration of the primary disturbance; and we may attribute to the following special disturbances the ensuing degeneration of the tracts whose functions are abolished or diminished:

1. That of the column of Goll, to the disturbance of a muscular sense in the lower extremities.

2. That of the comma-shaped internal bands of the column of Burdach, to the corresponding disturbance in the upper extremities.

3. That of the triangular area bordering on the periphery of the cord and posterior root entry, to the severe analgesic development.

4. That of the column of Clark and direct cerebellar (Foville's) tract to the disturbed space sense.—*The Alienist and Neurologist*, July, 1885.

TREATMENT OF ECZEMA IN REGIONS COVERED WITH HAIR.—Taking the scalp as a region—for which the directions laid down may be generalized in the treatment of eczema of hairy parts—it is recommended that the head at first should be thoroughly washed two or three times with soap, in order to insure the cleanliness of the affected parts. After this has been done, daily applications of the following preparation should be made:

℞.—Acid. salicylici . . . . . gr. x.
Tr. benzoini . . . . . gtt. xx.
Vaselini . . . . . ℥j.—M.

If a topical application is desired, which will more readily dry the parts, the following is recommended:

℞.—Acidi salicylici . . . . gr. xv.
Amyli
Zinci oxidi . . . . āā ℥iv.
Vaselini . . . . . ℥j.

—*Journal de Médecine de Paris*, July 26, 1885.

CASE OF PROGRESSIVE PARALYSIS OF THE ULNAR NERVE, CONSEQUENT UPON INJURY; OPERATION; SUCCESSFUL RESULT.—MR. CHAUNCY PUZEY, Surgeon to the Liverpool Northern Hospital, reports an interesting case of progressive paralysis of the ulnar nerve consequent upon injury and which was successfully treated by operation. The patient, a boy, aged 15 years, was caught between a "travelling-band" and the wheel

Digitized by Google

over which it passed, with the result of a compound fracture of the bones of the forearm. Forcible extension was required to restore the fragments into their proper position. The case was treated antiseptically, and with the exception of a somewhat slow union of the fragments of the ulna, no trouble was experienced at this time.

But the interesting feature of the case appears later on. The lad had ceased to be an inmate of the hospital after a month's treatment, and was attending as an outpatient, on account of the non-union of the ulna, when it was noticed that there was a tendency to obstinate flexion of the fingers, more especially of the little and ring fingers. A hinged splint, by which elastic extension can be used for the purpose of straightening contracted fingers or hands, was therefore applied; and in a day or two the patient presented himself, with the ring and little fingers blistered and discolored by the pressure of the splint and bandage. This, of course, at once led to inquiries as to the state of the ulnar nerve; the rest of the hand appearing quite healthy. Then it was ascertained that the lad (who had always been most patient and uncomplaining) had experienced curious sensations, partly of pain, partly of numbness, ever since the accident; and now it was found that the affected fingers were deficient in sensibility. The natural conclusion was that the nerve had been pinched or bruised by the sharp edge of the bone at the time of the accident. There was reason to believe that the nerve had not been divided, and we hoped that the effects of the injury would pass off.

But they did not; and gradually the numbness increased, and the fingers wasted at the tips; the circulation was very sluggish, the fingers purple and cold, the skin moist and clammy. Then the interossei and the lumbricales wasted, and the adductor pollicis and the muscles of the little finger followed suit. Combined with the numbness, there was evidently a considerable amount of pain felt on any attempt being made to straighten the flexed fingers; and a dragging sensation was complained of at the seat of the fracture, just above which, pain was felt on pressure. The symptoms, therefore, pointed to gradually increasing compression, or constriction, with adhesions of the nerve at this point.

As before mentioned, the interosseous spaces, both on the dorsal and on the palmar aspects, were hollowed out; the muscles of the ball of the thumb, and those of the little finger, were much wasted. With regard to the cutaneous sensibility, there was complete anæsthesia of all the surface usually supplied by the ulnar nerve, and also incomplete anæsthesia of the adjacent sides of the middle and ring fingers (due, no doubt, to this being one of that minority of instances where the ulnar nerve supplies two and a half, instead of one and a half, fingers).

On April 28th, I proceeded to explore the site of the fracture of the ulna, which was now firmly united, but was marked by a slight thickening of the bone. An incision was made, as for exposing the ulnar artery, the centre of the incision being over this thickened portion. Neither artery nor nerve was to be seen, though carefully searched for; the bone was reached; the fracture was found satisfactorily united, the upper fragment projecting very slightly above the lower; there was some thickening from callus, and, moreover, what seemed to be a band of thickened periosteum, tightly stretched over the callus. The question arose, Was this the sought-for nerve? The wound was enlarged upwards and the nerve was then found unmistakably, and traced into this band; then the wound was extended downwards toward the wrist, and what appeared to be nerve was found, and proved to be continuous with the band; but, whereas the nerve above the adhesion was pink and fleshy looking, the part below was colorless and wasted. Partly by the knife, and partly by gentle elevation with a raspatory, the nerve was freed from the bone. We then had between two and three inches of ulnar nerve completely free, so that it could be lifted above the level of the wound, and thoroughly examined. The upper part was, as before mentioned, pink and fleshy looking, evidently swollen; the part which had been fixed down was thinned and flattened, ragged from small tags of fibrous tissue attached to it; and the lower end of the nerve was round, but pale, and apparently wasted. To prevent the lately adherent portion from dropping down into its old situation, and probably again becoming attached to the bone, I connected a few fibres of the flexor carpi ulnaris with the adjacent flexor profundus digitorum by one catgut suture, thus interposing a fleshy bed between nerve and bone. The wound was then closed and dressed in the usual Listerian method.

On May 1st (three days after), Mr. Horrocks, the senior house-surgeon, notes that "the patient was able to tell when the skin on the proximal phalanges of the little and ring fingers was pinched, and appeared to have perfect sensation along the adjacent sides of the middle and ring fingers."

On May 7th (ten days after the operation), he notes "sensibility of fingers increasing, and extending downwards toward the tips, which are, however, at present insensible, The patient made the remark that, for the last two or three days, he has had a sensation as of blood rushing along toward the finger-ends."

On May 20th, the wound was quite healed, and tactile sensibility was rapidly increasing, being more acute in the ring finger than in the little, in the proximal than in the second phalanges, almost absent in the last phalanges. The improvement since that date has been slow, but steady and persistent, until now (eight months after the operation), there is hardly any appreciable difference between the two hands. Tactile sensibility appears to be perfectly restored; the hand is now natural in shape, the interosseal spaces having become perfectly filled by their proper muscle; and the muscles of the thumb and little finger are restored to their normal state. The color of the skin and of the nails is natural. The lad has returned to his work in the mill.

It should have been mentioned that until quite recently he has had some pain in, and tendency to flexion of, the index finger, with disordered nervous sensations therein; and forcible extension of the finger has always, until recently, given rise to a dragging sensation at the site of the old fracture. Probably, a small portion of the median nerve, or rather of its anterior interosseous branch, sustained injury through the compound fracture of the radius, and some adhesions took place in that locality; and these, as he has began to use his arm, have become stretched or broken down.

I alluded to the fact of our not being able to find the

Digitized by Google

ulnar artery in the wound. The probability is that it was so crushed by the sharp bone, that it was either divided or so damaged that it became impervious immediately after the injury.

It may occur to some that an exploratory operation should have been performed earlier. Possessed of the wisdom which comes after the event, it certainly does appear that an earlier operation would have been, at all events, justifiable; and, with the knowledge gained in this instance, I should feel disposed, should I meet with a similar case, to operate before such a condition of paralysis was reached.—*The British Medical Journal*, May 16, 1885.

LEPROSY AS OBSERVED AT CONSTANTINOPLE.—M. CONSTANTINE PAUL, at a meeting of the Académie de Médecine de Paris held July 28, 1885, in the name of the commission composed of himself and M. Cornil, read a report upon a memoir of Dr. Zambaco upon leprosy as observed at Constantinople.

The paper of Dr. Zambaco was specially devoted to the study of tubercular leprosy, and the conclusions reached were as follows:

1. Leprosy is not a hereditary disease. It is acquired possibly by contagion, but neither the clinic nor experimentation upon animals or upon man has yet been able to demonstrate this fact. The negative results of clinical investigations, and the failure of inoculation experiments, show that the disease is not easily transmitted, and that there is no proportion between the possible chances of contagion and the severity of the precautions which, in the Orient, are taken against it.

2. At Constantinople, as in Norway, lepers are affected with eye disease in the proportion of two-thirds or three-fourths.

These affections attack the cornea, iris, and crystalline body—with this difference, that the tubercular form is more frequently announced by a keratitis, while the anæsthetic form produces changes in the cornea and conjunctiva as a result of orbicular paralysis, which prevents retention of the lachrymal secretion.

3. Therapeusis consists in the combination of general treatment by tonics, such as quinine, arsenic, ergot, and of local treatment by destruction of the tubercles by means of the thermo-cautery.—*L'Union Médicale*, July 30, 1885.

THE CHOLERA BACILLUS.—FINKLER and PRIOR, in a forthcoming pamphlet, present the following *résumé* of their views:

1. We confirm the existence of Koch's comma-bacillus in the contents of the intestines and in the dejections of patients who suffered from cholera Asiatica in Genoa in 1884.

2. We have discovered the comma-bacillus in the feces of cholera nostras patients; we have thus found them directly by means of the microscope, and we were the first to breed them in pure culture fluids as well as the first to describe them.

3. These two kinds of comma-bacilli are vibrios which form genuine spirillæ. In reference principally to their morphological rank, as well as in relation to the changes which they may undergo in form, the two vibrios are alike.

4. The conduct of both in cultures agrees in most kinds of culture procedures. Differences manifest themselves only under very closely related conditions of culture surfaces and temperature, and declare themselves not so much by *absolute* as by far more *relative* peculiarities, namely, greater energy of growth and of vitality of the vibrio of cholera nostras.

5. Of the physiological characteristics of these vibrios, we especially denote, and have already done this in an earlier paper, their marked capability of resistance against drying, against different temperatures, and against putrefaction.

6. We maintain the possibility of a condition of tenacity, and consider it probable that this tenacity of existence resembles that of one of the spores of some other microörganism of similar formation.

7. Both vibrios are pathogenic.

8. The pathogenity of Koch's vibrio is greater than that of the Finkler-Prior vibrio; this also is only a question of *relative* difference.

9. The pathogenic character does not manifest itself in all kinds of animals; far more, rather, a great number of animals possess immunity against both vibrios. They manifest themselves only under certain conditions. The animals which are susceptible to and the conditions which are favorable for the action of the bacilli are the same for both vibrios.

10. The evidences of the disease called forth by the vibrios in the bodies of animals possess a certain similarity to those of cholera in human beings; they are, however, not specific, but in the guinea-pig can be imitated by means of other infectious matters and by chemical poisons.

11. The causative connection between the comma-bacillus and cholera Asiatica is most probably shown by the constant presence of the bacillus, but is not to be considered as certainly proved by experiments on animals. The causal connection between the comma-bacillus (discovered by us) and cholera nostras is probably shown on the one hand by the constant discovery of the microörganism, on the other, by the extreme similarity of the symptoms of cholera nostras to those of cholera Asiatica, as well as in the biological and pathogenic peculiarities of the two comma-bacilli.

12. The two vibrios can reach the blood after being injected into the intestines, and are secreted in the urine. The sojourn of the Koch bacillus in the body of an animal creates an increase in the rapidity of its growth, so that thereby a still greater similarity between the two vibrios is attained in their demeanor in culture.—*Boston Med. and Surgical Journal*, August 13, 1885.

CONGENITAL LATERAL DEVIATIONS OF THE UTERUS AND THEIR RELATIONS WITH PERIUTERINE TUMORS, AND THE MECHANISM OF LABOR.—PROFESSOR LAZAREWITCH, in a contribution to the *Annales de Gynécologie* for July, 1885, wherein he discusses congenital lateral deviations of the uterus, and their relations with periuterine tumors and the mechanism of labor, sets forth the following propositions:

1. *Congenital retro-position* of the uterus depends upon the shortening of the sacro-uterine ligaments. In this position of the uterus readily originate:

a. Anteversion or anteflexion.

b. The location of tumors behind or above the body of the uterus.

Digitized by Google

c. During pregnancy and confinement deviation of the neck of the uterus behind or above, and sacciform dilatation of the anterior wall of its lower segment.

d. During recovery after confinement anteversion and retroversion are very pronounced.

2. *Congenital ante-positions of the uterus* depend upon shortening of the anterior wall of the vagina. In this position of the uterus there occur frequently:

a. Version and flexion of the organ posteriorly.

b. The occurrence of tumors anterior to the organ.

c. During pregnancy and confinement deviation of the neck of the uterus before and above, and sacciform dilatation of the posterior wall of its inferior segment.

3. Congenital lateral displacements, right or left, of the uterus, depend upon failure in the development of the broad ligament, the ligament of the ovary, the sacro-uterine ligament, or upon failure in the development of the wall of the vagina, by which the uterus is brought into a closer relation with the pelvis. Lateral deviations of the uterus dispose:

a. To lateral version and to lateral flexion of the organ.

b. To a condition in which tumors may occur before or behind the uterus.

e. During pregnancy or confinement to a latero-version of the uterus, and to unilateral sacciform dilatation of its lower segment.

d. During the sequelæ of confinement to latero-version of the uterus.

UNGUENT FOR THE TREATMENT OF TINEA.—DESCROIZILLES recommends the following unguent for the relief either of *tinea tonsurans* or *tinea favosa*:

℞.—Butter of cacao,
Wax . . . . . āā ʒiiss.
Croton oil . . . . . f ʒv.—Mix.

Cut the hair short and remove the scales by the use of oil, then for a half minute or more, with light friction, apply a small quantity of the unguent to the diseased parts. The skin and the hair follicles soon become inflamed, and the fall of the hairs infected by the parasites is thus occasioned.—*L'Union Médicale*, August 1, 1885.

PILLS FOR PROFUSE PERSPIRATION.—

℞.—Agaricine . . . . . gr. viij.
Pulv. ipecac. et opii comp. . . gr. lxxv.
Mucilaginis . . . . . q. s.—M.
S.—Ft. pil. No. c. One or two pills daily.

Agaricine does not, like atropia, produce symptoms of intoxication when continued a long time.—*Journal de Médecine de Paris*, July 19, 1885.

ODORLESS IODOFORM.—DR. OPPLER recommends the following preparations of iodoform as being free from objectionable odor:

℞.—Iodoformi . . . . . 2 parts.
Caffeæ tostæ subtilissime pulv. . 1 part.
M.—Fiat ope spirit. æther. gtt. pulv.

℞.—Iodoformi . . . . . 1 part.
Ung. paraffin. . . . . 10 parts.
Caffeæ tostæ subtilissime pulv. . . 3 parts.

—*Centralbl. für Chirurgie*, July 25, 1885.

CASE OF CONGENITAL ABSENCE OF THE RIGHT KIDNEY.—DR. HOFACKER reports a case of congenital absence of the right kidney. The case is as follows: A post mortem was held on a child eight years of age, who had died of caries of the ilium and sacrum. The right kidney having been discovered to be absent, attention was drawn to the unusual development of the left kidney. This was nearly five inches in length and nearly three inches broad, double the size corresponding to the age and development of the child. Upon the right side no trace of a kidney was to discovered. To the left kidney a large renal artery proceeded, while on the right side no trace of this vessel existed, the aorta at the ordinary point of origin of the vessel being perfectly smooth; the right renal vein was also absent. In the bladder there was no opening corresponding to the entrance of the right ureter, but only a slight depression by which the trigone of the bladder was preserved. From the outer wall of the bladder it was possible to trace through the retroperitoneal connective tissue a cord which in one place permitted the entrance of a bristle and lost itself in the region corresponding to the normal location of the right kidney. This, without doubt, represented an undeveloped ureter.

The vasa deferentia were normal. The seminal vesicle on the right side was rudimentary and smaller than that of the left. The right testicle was absent. The bifurcation of the aorta was normal, and other abnormalties in the development of the different organs were not discoverable.—*Deutsche med. Wochenschr.*, July 23, 1885.

PHYSIOLOGICAL EXPERIMENTS UPON A DECAPITATED CRIMINAL.—MM. P. REGNARD and P. LOYE, in a series of physiological experiments made upon a decapitated criminal immediately after execution, consider that the following facts are established:

1. That sudden and general contractions occur at the moment of excitation of the spinal cord by the passage of the guillotine.

2. The disappearance of the reflexes, even the coarsest.

3. The evident action of the pneumogastric upon pulmonary contractility.

4. The manifest influence of the fibres of Reissessen upon this same contractility.

5. The innervation of the stomach and intestines due to the pneumogastric.

6. The plain influence of the vagus upon intestinal secretion.

7. Finally, verification of the mechanism of the muscles of the heart.

These physiological experiments simply confirm the results of those hitherto made on animals.

On the other hand, MM. Regnard and Loye hold that the facts observed in reference to duration of consciousness, may possibly confirm the belief of those psychologists who fear its persistence after capital punishment.—*Le Progrès Médicale*, July 18, 1885.

THE USE OF LACTIC ACID IN LARYNGEAL TUBERCULOSIS.—DR. H. KRAUSE, in following up the experimental application of lactic acid as pointed out by V. Mosetig-Moorhof, who has found it valuable in the local treatment of fungous caries, lupus vulgaris, super-

Digitized by Google

ficial epithelioma, and papilloma, has made use of the remedy in the local treatment of laryngeal tuberculosis. The cases which he records had previously been under treatment, and a great variety of agents was used without beneficial result. Among the remedies used were iodoformized glycerine, boric acid, carbolic acid, and creasote either with morphia or cocaine.

The cases in which the pathological condition was treated are fourteen in number, and microscopic examination showed the presence of the bacillus tuberculosis in every instance. The results of the local application of the lactic acid were as follows: Hand-in-hand with the decrease of the infiltration and the scar of the ulcer a diminution of pain was noticed, and at the same time diminution of the secretion. The subjective result so far as the larynx is concerned is, that in all the patients, without exception, the condition was markedly improved.

Concerning the return and persistence of the cure after cessation of treatment nothing can be reported on account of the limited time covered by the observations. Dr. Kraus considers, however, that the use of the acid is of certain efficacy in the treatment of this form of tuberculosis, and especially worthy of trial in the light of the failure hitherto experienced in the treatment of this affection of the larynx.

Even in cases in which, owing to far advanced pulmonary tuberculosis, and the general effects of the disease, only a most unfavorable prognosis could be given, the dysphagia accompanying the disease was much diminished by lessening perichondrial œdematous infiltration. The writer further does not hesitate to express a hope that in the least unfavorable cases in which laryngeal tuberculosis has not advanced too far, and the general constitution is well conserved, the use of lactic acid will render it possible to destroy the infiltrated tissue and effect the concurrent cure of the local process. The writer, in conclusion, also suggests the application of lactic acid in other diseases of the mucous membrane of the upper air-passages, among which may be mentioned the diffused swelling and circumscribed thickening accompanying chronic nasal pharyngeal and laryngeal catarrh.—*Berliner klin. Wochenschr.*, July 21, 1885.

THE DEPRESSING ACTION OF IPECAC ADMINISTERED IN LARGE DOSES UPON THE BLOODVESSELS IN PNEUMONIA.—DR. FERDINAND VERARDINI, in an excellent clinical and experimental study of the action of large doses of ipecac upon the bloodvessels in pneumonia, reaches the following conclusions:

1. Large doses of ipecac have been given empirically during past years by the most prominent physicians, as a depressing and antiphlogistic remedy in fibrinous pneumonia.

2. The use of large doses of ipecac (30, 60, 90, 120 grains, according to the case, and administered in twenty-four hours) has no harmful influence upon stage of sanguineous stasis, nor upon cardiac paralysis, and its emetic effect is only manifested exceptionally.

3. Without doubt the doses under consideration have beneficial influence upon the disease by diminishing the flow of blood to the lungs, and by facilitating the resolution of the pneumonia without causing the least risk to the patient.

4. That large doses of ipecac produce effects in the organism distinct from those of emetia. M. Verardini thinks he is the first to mention this fact. In reality, ipecac produces pulmonary ischæmia, although the active principle, emetia, occasions a very pronounced hyperæmia. These facts have been recognized experimentally.

6. The author, by producing simple pneumonia in animals, by means of divers irritating substances, such as cantharidine, ammonia, and pneumonic sputa, carried directly by the bronchi into the pulmonary parenchyma, has been able clearly to establish the comparative action of ipecac and emetia upon the heart and lungs.—*L'Union Médicale*, July 30, 1885.

CHOLECYSTOTOMY.—M. THIRIAR, in a communication to the French Congress of Surgery (*Revue de Chirurgie*, No. 5, 1885), deals with the following objections to cholecystotomy, an operation first performed by Langenbuch, of Berlin, in 1882. 1. The existence of a gall-bladder is necessary for the purposes of digestion in man. 2. Calculi may be formed elsewhere than in the gall-bladder. 3. The operation is a very serious and dangerous one. 4. Cholecystotomy or the production of a biliary fistula ought to be preferred. It is argued by M. Thiriar that the gall-bladder is not indispensable to the regularity of the digestive functions in man. This organ is absent in many of the mammalia, and occasionally it is found completely closed and atrophied in man. The formation of calculi elsewhere than in the gall-bladder is an extremely rare occurrence, except in certain pathological conditions which give rise to such formation in the biliary ducts and canals. These pathological conditions (cancer, obstruction of the biliary passages), however, constitute a formal contra-indication to operative interference. Cholecystotomy, it is acknowledged, is decidedly a difficult and delicate operation, but in considering the much diminished dangers of peritoneal lesions when produced with strict observance of the antiseptic method, M. Thiriar is of opinion that this procedure is the least severe and the least dangerous of all the varieties of laparotomy. It is a justifiable operation, he holds, in cases of biliary lithiasis that have resisted medical treatment, and in which violent paroxysms occur from time to time. With regard to the operation of cholecystotomy that has been proposed by Mr. Lawson Tait, although it is less difficult than cholecystectomy, it is attended by the inconvenience of leaving a biliary fistula, a condition not free from danger. Moreover, as it does not remove the organ in which gall-stones are formed, the production of these bodies may be continued. Two cases of cholecystectomy are reported in this paper. In one, the patient was a woman, aged 43. The gall-bladder contained a mass of thick bile, but no calculus. The operation lasted during one hour and a half, and resulted in complete success, without any complications. The subject of the second case was a woman in the fifth month of pregnancy. The gall-bladder contained twelve calculi. The operation lasted during one hour, and proved successful. The progress towards recovery was uninterrupted, and the pregnancy followed the usual course.—*The London Medical Record*, July 15, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET.
PHILADELPHIA.

SATURDAY, AUGUST 22, 1885.

THE CHOLERA.

SINCE our last editorial on "Cholera Prospects," in THE MEDICAL NEWS of July 25th, the situation in Europe has materially changed for the worse The disease is spreading in Marseilles, cases have occurred in Gibralter, and a suspicious case has been reported from Bristol, England, causing considerable alarm in that country. In Spain cholera has continued to increase, and for the last week there have occurred in that country between five and six thousand cases and about fifteen hundred deaths per day, and the situation in certain localities, as described in the press despatches, is very gloomy, recalling the descriptions of scenes during the black death of the middle ages. In some villages all the physicians are dead, and dead bodies are lying in the streets, there being no one to bury them. The revenues of the kingdom are beginning to suffer seriously, and the Government finds it difficult to provide funds to meet the demands made upon it for assistance.

Any day may bring the news that the disease has gained a foothold in England, or in South America, or in West Indian ports in immediate communication with Spain. This country is therefore not only in danger, but in immediate danger, and our health authorities must hold themselves ready for the emergency. We do not anticipate that such scenes as have occurred in Spain will be repeated either in Great Britain or the United States, nor do we fear a great epidemic in either country, knowing the power which exists to stamp out the contagion by prompt and intelligent action.

An example of what can be done in this way was afforded in the city of Genoa last year. This city receives its drinking water by three different aqueducts drawing from three different sources. The first case of cholera appeared in Genoa on the 20th of September, and for the next three days there were two or three new cases each day, but on the 25th there were 51 cases. Investigation showed that no cases of cholera had existed in the vicinity of the sources of two of the aqueducts, but that the third might have been contaminated by cases which occurred on one of its feeders, fourteen miles away, on the 14th and 15th of September; and that of the first fifty cases of cholera in the city, 48 occurred in persons who habitually used the water brought by this aqueduct. The mayor of the city at once had this aqueduct closed, and by the first of October the daily number of cases of cholera had dropped to 27, from which date it rapidly disappeared. In this case skilled investigation located the cause and the executive action was prompt.

The next two months will be very dangerous to the north of France, Germany, the Netherlands, and Great Britain, and dangerous to this country, but we still have good reason to hope that the visitation of cholera to the United States will be deferred until next year, and thus permit another winter of sanitary work and preparation for what is almost sure to come sooner or later.

CHLORATE OF POTASSIUM POISONING AND ITS MORBID ANATOMY.

PERHAPS few announcements created more surprise, and few have been more incredulously received than that chlorate of potassium is a poison, and that instances of its poisonous effects are numerous. The first assertion is, however, undoubtedly correct, while the second also, must be admitted, if accuracy has been employed in the collection of cases, since, for instance, a thesis by Weinert is based upon a record of fifty cases, and Wegscheider has collected thirty cases.

It is true that most of the instances of poisoning reported are by quantities which are scarcely likely to be often taken, but, in the case of a remedy which has been so highly and universally esteemed, and which has generally been regarded as harmless, it becomes essential that all should appreciate its exact toxicological position. Accordingly, we avail ourselves of a case recently reported by Dr. Wilke, of Halle, in the *Berliner klinische Wochenschrift*, for April 20, 1885, in which the use of the salt as a gargle resulted fatally.

The patient, whom Dr. Wilke saw about 3 o'clock of August 8th, had, previous to his present illness, enjoyed good health. In the early part of the night previous he was restless, and therefore his wife did not arouse him early; when, however, she went to his bed, she found him unconscious, and subse-

Digitized by Google

quently aggravated biliary vomiting set in. Closer examination discovered extreme pallor, a cyanotic skin, cool extremities, a small and frequent pulse, and a temperature below normal, although it was impossible to determine it precisely by the thermometer, on account of the patient's restlessness. The mouth could only be opened by using great force, but there were perfect motor power and sensibility. The lungs were normal, the heart simply weak. There was tenderness over the stomach and its neighborhood, but some of this may have been due to a mustard plaster which had been applied by the physician previously in attendance. The remaining abdominal organs were healthy, and a healthy stool was secured by an injection.

Dr. Wilke at once suspected poisoning by some cause. No urine had been passed since the previous evening, a teacupful of dark-hued, turbid urine was drawn off by the catheter. This suggested to him chlorate of potassium poisoning. On further questioning, he learned that none had been taken internally, but that in consequence of a slight sore throat the patient had, for some time, been gargling his throat with a solution of the salt. Recently he had used it hourly, and had done so even the night previous. He had always bought from the apothecary large quantities of the drug, and being a very nervous man, even hypochondriacal about his throat, was determined to cure it at any price. Lately he had become very weak and pale, and two weeks previously had noted his urine to be so dark-colored that he sent for his physician, and consulted him as to the propriety of using the gargle. The doctor took some of the water, but seems to have made no report on it, giving the opinion that, as the potash was being used only as a gargle, it could not harm him. The patient continued to use the gargle from the 9th of July to the 8th of August, taking, it was estimated, over four pounds, or one and three-fifths ounces a day. Treatment was unavailing, and he died of collapse.

At the autopsy only a trifling amount of blood flowed from the abdominal aorta and vena cava, although great care was taken to secure it. The bladder was empty, but the urine drawn off before death contained a black sediment which the microscope showed to be made up of red corpuscles whose normal characters were markedly altered. They were, in various degrees, paler than in health. Some had apparently lost all their coloring matter. None were disk-shaped, but almost all spherical. Some were, however, elongated; some uneven and irregular. Most were smaller, but a few were larger than the normal disks. The smallest were disposed to adhere, but rarely was there any appearance of fibrin between them. Casts of the uriniferous tubules were also present, characterized by their unusual width and their irregular surface, and there were a few leucocytes, some of which contained some of the smaller corpuscles.

The kidneys were of normal size, the capsule stripped off readily. The external surface and section were darkened, and the pelves contained a sediment which agreed with that found in the urine. Dark brownish red striæ were observed in the cones running parallel with the straight tubes, and in the cortex were similar striæ less wide and less numerous, and more irregular in their course. These were found to be uriniferous tubules, distended with altered corpuscles, most numerous in the medulla and especially the neighborhood of the papillæ. In the cortex the tubules of the medullary rays were more often distended than the convoluted tubules of the labyrinth. In addition to the individual corpuscles contained in the tubules, there were also numerous irregular, lumpy, and cylindrical bodies apparently made up of the altered red corpuscles, or in some cases of their shells, as it were, fused into an infarcted mass. The epithelium of the tubules, where discoverable, was highly granular, especially in the cortex, where the nuclei of the cells were often obscured or invisible.

Granted, as seems necessary, that the above is a case of true chlorate of potassium poisoning by the drug used as a gargle only, it must also be admitted that such cases are extremely rare. That a man should use nearly an ounce and a half of the salt daily, for one month, in gargling his throat, almost presupposes a monomania on the subject, and it would seem exceedingly unlikely that such an experience should be often repeated, or that the use of the salt as a gargle is a dangerous practice. But Wormley, in his *Michro-Chemistry of Poisons*, reports a case related by Croft, in which a young woman, directed to gargle with a solution of potassium chlorate, and occasionally swallow a little of the solution, used nearly half a pound of the salt within a few days. Violent symptoms including vomiting, diarrhœa, subsequent constipation, and suppression of urine were followed by death in seven days.

Much smaller quantities internally administered are capable of producing poisonous consequences. Wormley reports another case in which a man took, in teaspoonful doses, during thirty-six hours, about two ounces of the salt. Collapse and suppression of urine were followed by death. Still another in which four children, from three to seven years old, took 154, 184, and 375 grains in, at most, thirty-six hours. All three died. An elderly man took, by mistake for Epsom salts, something over half an ounce and died in consequence. The autopsies in all these instances revealed conditions strikingly like those described in Wilke's case.

It is the domestic use of the medicine which is

Digitized by Google

most to be feared. The extreme frequency of throat affections in this climate, and the almost invariable use of chlorate of potassium for them, together with the prevailing impression that the drug is harmless in almost any quantity, make it not impossible that accidents like that just detailed may occur.

THE ETIOLOGY OF POLYHYDRAMNIOS.

THE origin of the amniotic liquor has been the subject of many investigations and of much discussion. Some have asserted that this liquor is a maternal, others a fœtal product, while the view now generally accepted is that it is partly derived from the mother and partly from the fœtus. Kormann, the most recent writer of a German work upon obstetrics, published at Tübingen in 1884, regards the amniotic liquor as coming from the vessels of the cord, from the vessels beneath the amnion, described by Jungbluth, and the vessels of the reflexa, and as partly, especially in the last months of pregnancy, consequent upon the activity of the kidneys of the fœtus. Afterward in considering the various causes of hydramnios, he fails to refer to its possible origin from the blood-vessels of the cord. Yet it would seem rational that if the amniotic liquor is in part due to the serous portion of the fœtal blood passing from the vessels of the cord, that there might be such excessive transudation as to cause hydramnios.

A most interesting case of hydramnios sustaining this hypothesis has recently been published by MANGIAGALLI in the *Annali di Ostetricia*. A woman near the end of a twin pregnancy suffered so much from distention, that puncture of the ovum presenting was made. The quantity of fluid discharged was small, but the alleviation of the patient's distress was very decided. Labor came on, and she was delivered of a living child by the forceps. The second bag of waters was then ruptured, six litres of water discharged, and the second child, presenting by the breech, was born. An examination of the secundines showed that there were two distinct pouches and two placentæ. One of the cords presented nothing abnormal, but the other, belonging to the hydropic sac, was only eleven inches long, encircled the child, and at two and one-third inches from the placenta it divided so that its parts were inserted in the partition wall between the two ova—upon this wall four very large ramifications of the umbilical vein, which was also large and distended, passed to the placenta—there being thus velamentous insertion of the cord.

Mangiagalli believes that the chief cause of hydramnios in this case was the increased tension in the umbilical vein and its vicinity by the abnormal disposition of the cord and its vessels.

A case reported by SCHATZ in the *Archiv f. Gynakologie*, 1882, presented the same condition of scanty liquor amnii in one pouch, and excess in the other.

GRENSER, in the *Centralblatt für Gynäkologie* of July 11th of this year, has reported two additional cases of this anomaly, occurring in twin births, in one sac of each there was polyhydramnios, and in both the others, oligohydramnios.

MUCIN.

STILL another of the proteids, which, according to many urinologists, interfere with the reliability of certain tests for albumen, is mucin. A very much more frequent constituent of urine than either peptone or propeptone, it is correspondingly important that it should not be mistaken for albumen. That hemialbumose or propeptone is an unusual constituent of urine is generally understood; but so much has been written, of late, of peptone, that there is danger of it being supposed that it is very common. But Dr. Johnson, who has made a systematic search for peptone, found it but once in some hundred specimens of urine. Mucin, on the other hand, is a much more constant constituent, and in the light of the latest information, we feel assured that many have not infrequently mistaken it for albumen.

A few words as to mucin itself. The glairy semi-transparent substance known as mucus, so familiar to all of us by its appearance in the nasal and respiratory passages in response to the slightest irritation, is mucin swollen by imbibition of water. But the words mucus and mucin are also interchangeably used. According to the analysis of Eichwald, mucin contains in 100 parts, 49.94 of carbon, 6.80 of hydrogen, 8.5 of nitrogen, and 35.75 of oxygen, but no sulphur. It completely disappears on ignition. It is abundantly present in the salivary glands, in the bile, in the contents of synovial sacs, in the mucus of the bronchial and intestinal mucous membranes, in the Whartonian jelly, and to a slight extent, it is said, in many, if not all, urines. In certain morbid urines it is very abundant.

It swells up enormously in water, without, however, being dissolved by it, but is soluble in dilute alkaline solutions, such as the urine, whence it is precipitated by acetic acid, an excess of which does not dissolve the precipitate. It is precipitated by alcohol, by all dilute mineral acids and by all the organic acids, including citric and acetic, and excepting, according to Dr. Johnson, picric acid. It is dissolved by concentrated mineral acids, but precipitated from solution in these on the addition of water. The presence of alkaline salts facilitates its solution in acids. The neutral and alkaline solutions of mucin are not precipitated by cupric sulphate, corrosive sublimate, or neutral acetate of lead, but

Digitized by Google

promptly by the basic acetate of lead. Millon's reagent strikes with the solutions of mucin, in connection with heat, a rosy-red color. After heating with hydrochloric acid mucin gives the sugar reaction with Trommer's test. It will be seen from the above, how important is a knowledge of mucin and its properties.

In consequence of its capacity to act as a ferment, on account of which it is held responsible for the acid and alkaline fermentations of urine, mucin has been called by Bechamp, nephrozymase.

As to the recognition of mucin, it is well known that in inflammatory diseases of the urinary passages it is often so abundant that it is easily recognizable in suspension in the urine. From solution in urine it is precipitated by any of the vegetable acids, though acetic is mostly used. If urine be underlaid with acetic or nitric acid, the mucin gradually appears in the urine above the point of contact, as a cloud-like, rather than opaque white coagulum like albumen; and when albumen and mucin are both present, the latter appears at the upper part of the column of urine, while the albumen is confined to a position just above the point of contact between the two fluids. It differs from the somewhat similar white deposit of acid urates in that it is not dissipated by heat. It is plain, therefore, that any test which requires the simultaneous use of citric or acetic acid is liable to error from this source. Such, however, is not the case, according to Dr. Johnson, with picric acid, which is, therefore, according to him, the only one of the comparatively new tests for albumen which can be relied upon.

To demonstrate the smaller quantities of mucin it is usual to treat urine with twice its bulk of 95 per cent. alcohol, filter off the precipitate, and add water. The solution thus obtained is rendered turbid by acetic acid, and the turbidity does not disappear on adding an excess of acetic acid, but does on adding hydrochloric or nitric acid. It exhibits with caustic soda and solution of cupric sulphate the biuret reaction, which is not obtained with the filtrate after separating the precipitate with neutral acetate of lead.

AN EXTRAORDINARY CAUSE OF VESICO-VAGINAL FISTULA.

MASSALITINOW, in the *Centralblatt für Gynäkologie*, has reported two cases of severe injury in newly married women from the first coitus. In the one case there was very serious hemorrhage from a tear of the perineum, and also of the vagina. In the other, a healthy, nineteen year old girl, hemorrhage, less grave, however, occurred; and, upon examination, three days after, a urinary fistula was found near the margin of the uterus, which was anteflexed. Massalitinow explains the occurrence of this lesion by supposing that, the vagina being short, and, at the time of coitus, the bladder being full, hemorrhage into the vesico-vaginal wall occurred at this point, and then ulceration opened a communication between the bladder and the vagina.

This explanation does not seem quite satisfactory, and probably, as suggested by Reimann, there was in each case other violence than any done in coition to explain such lesions. It is to be regretted that men who inflict such cruel injuries upon women do not have as certain, swift, and severe punishment visited upon them as befalls the adventurous male bee who impregnates the queen.

UNDER the title of "Progress of Public Sentiment," the *Journal of the American Medical Association* in its issue of last Saturday, cheerily states that:

"Evidences are not wanting that the principal performers in the grand comic play of "Much Ado about Nothing," which was commenced so brilliantly on the 29th of June by twenty-eight prominent members of the profession in Philadelphia, are becoming weary of their work. Some who were induced to join in the play from the first impulse have already withdrawn, and others are evidently preparing to follow.

"Dr. John H. Packard, of Philadelphia, who was appointed Secretary-General of the Congress by the Committee of Arrangements at the meeting in Chicago, and whose name was published as one of the twenty-eight who declined to accept any place in the revised organization, has recently withdrawn his declination and accepted the position."

We are just informed by Dr. Packard that the above statement, so far as it concerns him, is absolutely false and without foundation, and that he has written to the Editor of the *Journal of the Association*, a letter for publication to that effect. While the New Committee has never had any claim to public support, we yet regret that, to stimulate its waning strength, it should still further estrange public confidence by again resorting to the method of wilful misrepresentation to which it owed its birth.

Under the circumstances it is necessary for the *Journal of the Association* to present the proof of the correctness of its statement concerning the intentions of other gentlemen, before the profession can give to it unqualified belief.

REVIEWS.

CHOLERA: ITS ORIGIN, HISTORY, CAUSATION, SYMPTOMS, LESIONS, PREVENTION, AND TREATMENT. By ALFRED STILLÉ, M.D., LL.D. 12mo. pp. 164. Philadelphia: Lea Brothers & Co., 1885.

A TREATISE ON ASIATIC CHOLERA. Edited and Prepared by EDMUND CHARLES WENDT, M D., in association with DRS. JOHN C. PETERS, of New York; ELY MCCLELLAN, U. S. A.; JOHN B. HAMILTON, U. S. Marine-Hospital Service; and GEORGE M. STERNBERG, U. S. A. With Maps and Engravings. 8vo. pp. 403. New York: William Wood & Co.

WE should be well prepared to meet this dread scourge if it crosses the Atlantic either this year or next

Digitized by Google

Ample warning has been given, and the sanitary authorities seem alive to the necessity of taking all proper precautions to avoid its importation. The publication of these works meets a demand on the part of the profession for fuller information on the subject than can be obtained from ordinary text-books.

Dr. Stillé's work supplies this demand in a way which will, we feel sure, meet the approval of every practitioner who reads this "complete but compendious history of the disease as it occurred at different periods and in various countries." The sections on prevention and treatment are specially valuable. The author does not accept the conclusions of Koch regarding the bacillus.

Dr. Wendt's treatise naturally lacks the unity and continuity of the smaller work, as it is in reality a series of essays on cholera by various authors, which will prove most serviceable for reference.

Dr. Peters gives in detail a history of the epidemics from the earliest up to the present one, dealing very fully with the American outbreaks. Dr. Ely McClellan describes the epidemics as they have occurred in the American army. The section on Etiology, by Dr. Wendt, is carefully prepared, and all possible theories are discussed. The recent investigations of Koch and others are fully discussed, and the Editor favors the view that the comma-bacillus will be found to be the specific germ of the disease. The chapters on Symptomatology, Course, Sequelæ, Morbid Anatomy, and Treatment are also by Dr. Wendt. Chapter XXXVII., on the Methods of Bacterioscopy, is a piece of unnecessary padding. Dr. Sternberg writes an interesting section on the destruction of cholera germs, and Dr. John B. Hamilton discusses quarantine and other preventive measures. Eight maps and charts, with several woodcuts, add to the value of the work.

THE INVALID'S TEA-TRAY. By SUSAN ANNA BROWN, author of "Forty Puddings," "In Bridget's Vacation," etc. Pp. 67. Boston: James R. Osgood & Co., 1885.

THIS slender little book, with its white margins of such unusual width, that a blankness overspreads the entire volume, is perhaps intended to be gently significant of the spareness of the diet which a sick man may be invited to enjoy. It is courteously dedicated to the family physician

> "Whose genial visit in itself combines,
> The best of cordials, tonics, anodynes;"

and after a few preliminary hints excellent in their character, the author gives some seventy or eighty recipes for various culinary preparations. These formulæ might easily have been printed so as to cover less than a couple of leaves, but by placing one or two only in the centre of a page the number of sixty-seven is attained. Page sixty for example, is thus constituted: "SHELLS. Put one cupful of shells in a quart of cold water and place on the stove where it will simmer gently five or six hours. Add more water, if necessary, while it is boiling. There should be about a pint when it is done."

For any specification to the contrary the "shells" here directed may be oyster-shells, and if such conchological specimens are used, exact instructions as to the degree of concentration required in the resulting concoction are surely needless.

SOCIETY PROCEEDINGS.

CHICAGO GYNECOLOGICAL SOCIETY.

Stated Meeting, June 19, 1885.

THE PRESIDENT, H. P. MERRIMAN, M.D., IN THE CHAIR.

PROF. J. H. ETHERIDGE read

A REPORT OF A CASE OF A FŒTUS ENCLOSED IN ITS SISTER'S PLACENTA, WITH EXHIBITION OF THE SPECIMEN.

On 26th September, 1882, Mrs. T. J. B., twenty-two years old, of a nervous, sanguine temperament, healthy, was delivered of a mature female child, after a normal labor of four hours' duration. During the delivery of the placenta some abnormity was detectable, which proved to be a *fœtus papyraceus*.

The outer surface of the placenta at once arrested attention. A deep furrow separated the two placentæ, which were united, on their amniotic surface, by a series of compact white bands, discoverable only by pressing through the furrow. The large placenta constituted about two-thirds of the entire mass. The smaller placenta was thin, flat, and compact, being about one-third as thick as the larger one.

The placenta of the living child was normal throughout its extent. Cotyledons were well marked, the tufts and villi presenting normal microscopical characters. The placenta of the *fœtus compressus*, in about nine-tenths of its extent, was whitish-yellow, and very firm. The whole thickness of this portion of the placenta, excepting its amniotic surface, presented one unbroken mass of fatty degeneration. The remaining one-tenth of the placenta presented a carneous appearance, evidently a transition stage between normal placenta and complete fatty destruction. Its cotyledons were enmassed and its tufts and villi solidified, and the whole interspersed with initial fatty depositions.

The two segments were wholly different at time of birth. The placenta of the living child presented a normal appearance. The placenta of the *fœtus papyraceus* presented the appearance of a closed bladder, which, upon examination, was found to be an unruptured amnion, containing amniotic fluid and a fœtus. The development of the *fœtus compressus* corresponded to the third month. The cord of the *fœtus papyraceus* was two inches longer than that of its fellow, and much thinner. The cord was inserted into the margin of the placenta, near the fully developed organ.

Among the causes producing the death of the fœtus, the following may be mentioned: 1. Faulty insertion of the cord, at the margin of the placenta, adjoining its fellow (Kieselhausen). 2. Faulty structure of the cord; thin, twisted, or deficient in the jelly of Wharton (C. Braun). 3. Disease of the placenta. 4. Traumatism. 5. The implanting of the umbilical vessels too closely together, and arterial anastomosis.

Fœtus papyraceus is of seldom occurrence. A search

Digitized by Google

through the library of the Surgeon-General's Office at Washington resulted in finding only five references to reports of similar cases.

DR. PHILIP ADOLPHUS thought that such cases were of more frequent occurrence than the remarks of the author of the paper would lead one to believe. In twin pregnancy, the death of one fœtus before parturition was not infrequent.

PROF. W. W. JAGGARD agreed with Dr. Adolphus that while such cases were rare, a more extended research into the literature of the subject would have revealed a much larger number of cases. While it was true that American and English text-books usually merely mentioned the fact of occurrence, German, French, and Italian treatises devote a chapter to the subject. The last edition of Schroeder contained an excellent *résumé* of the literature. The case, reported and exhibited by Prof. Etheridge, resembled in many points the case in the Pathological Museum of the Jena Lying-in Hospital, fully described by B. S. Schultze. This specimen showed the placenta of a mature fœtus, and adjoining it a second egg, corresponding to the sixth week of pregnancy, with its own decidua and unruptured amnion.

Prof. Etheridge's case was chiefly interesting as bearing upon a subject of theoretical importance, *i. e.*, superfecundation and superfœtation, On *à priori* grounds, it is possible that superfœtation can occur as late as the twelfth week of pregnancy—when *decidua vera* and *reflexa* become united. Up to this time, it is possible that egg and spermatozoid may come in contact. Superfœtation is also possible in cases of double uteri. Up to the present time, however, no case has been recorded which does not admit of a simpler explanation. There exists a great weight of evidence in favor of superfecundation. Mares give birth simultaneously to horse and mule foals; bitches, running during the period of rut with different breeds of dogs, throw young of different, so-called bastard forms, corresponding to the breeds of the male progenitors; the same is true of cats.

A woman may give birth to twins, one of which is white, one black. The latter fact, however, does not necessarily demand for its explanation intercourse at or near the same time with a white and a black man, since in crossing races the offspring may resemble either father or mother, or one child may resemble the male, the other the female progenitor. There could be no reasonable doubt as to the accuracy of Prof. Etheridge's diagnosis.

DR. JOHN BARTLETT had seen one case of *fœtus compressus*, in the Chicago Woman's Hospital, about four years ago. One fœtus was mature, the other corresponded in development to the fifth month of pregnancy.

DR. EDWARD WARREN SAWYER referred to the fact that in ectopic pregnancy no compression of the fœtus was observed. He alluded to a case, in which he performed laparotomy three and one-half years ago. The fœtus weighed eight pounds. There could be no question about superfœtation in Prof. Etheridge's case. Fœtation, by inclusion, might be considered as explanatory of many of the monstrosities which are so commonly seen.

PROF. DANIEL T. NELSON thought it would be interesting to know how much force was necessary to compress the fœtus as in Prof. Etheridge's specimen. He referred to the experiments of Prof. Park, of the Massachusetts Agricultural College, in the determination of the expansile force of growing squashes and pumpkins.

THE PRESIDENT wished to know whether the death of the fœtus occurred before compression, or whether it resulted from that factor. The marginal insertion of the cord doubtless was an important etiological agent. When the uterus was in the pelvic cavity, compression was greater. He referred to the fact that in twin pregnancies, it is unusual to find both children equally developed, and frequently the birth of one precedes that of the other by minutes, hours, or even days.

DR. HENRY T. BYFORD read a

REPORT OF A CASE OF LEIO-MYOMA OF THE VAGINA AND UTERUS.

The patient was a widow, about thirty-five years old. Was married ten years, without becoming pregnant. She had no decided symptoms of disease, except an occasional backache, some leucorrhœa. She was treated for uterine inflammation three years before, and no tumor was discovered. Since that time, she has menstruated every two weeks. Catamenia usually lasted five days, and were normal as to quantity. Twelve years ago, she noticed a tumor about the size of a hickory nut just within the vagina. This swelling had since that time grown steadily, until its protrusion from the vagina, about January 12, 1885, caused great inconvenience. Even at that time, the pain was promptly relieved by an opiate, administered by Dr. Doering. Two or three days subsequently, the tumor became black, swollen, and emitted a gangrenous odor. Slight septicæmia followed cauterization with nitric and carbolic acids. The tumor was attached to the anterior wall of the vagina. The tumor was subsequently crushed off, and the patient recovered. Indagation revealed a protuberance, about the size of a goose egg, upon the right anterior surface of the uterus, which was apparently a leio-myoma.

The following points of interest are to be noted in connection with the case:

1. The occurrence of both tumors in the same person.
2. The slow growth of the vaginal as compared with the uterine tumor.
3. Sloughing of the capsule, immediately after protrusion from the vagina, without impairment of the vitality of the tumor, proper.
4. Entire absence of sensitiveness to strong acids.
5. The production of a pedicle by ligaturing the proximal end with a fine wire.
6. Sterility, antedating the discovery of the uterine tumor.
7. The influence of ergot upon the uterine tumor.

DR. EDWARD WARREN SAWYER thought the locality of the vaginal tumor was interesting but not unusual.

PROF. DANIEL T. NELSON inquired whether or not fibroid tumors occurred by preference in the anterior vaginal wall. He thought, as regards the operation, an elliptical incision around the base, and enucleation of the tumor, would have fulfilled the indications equally well.

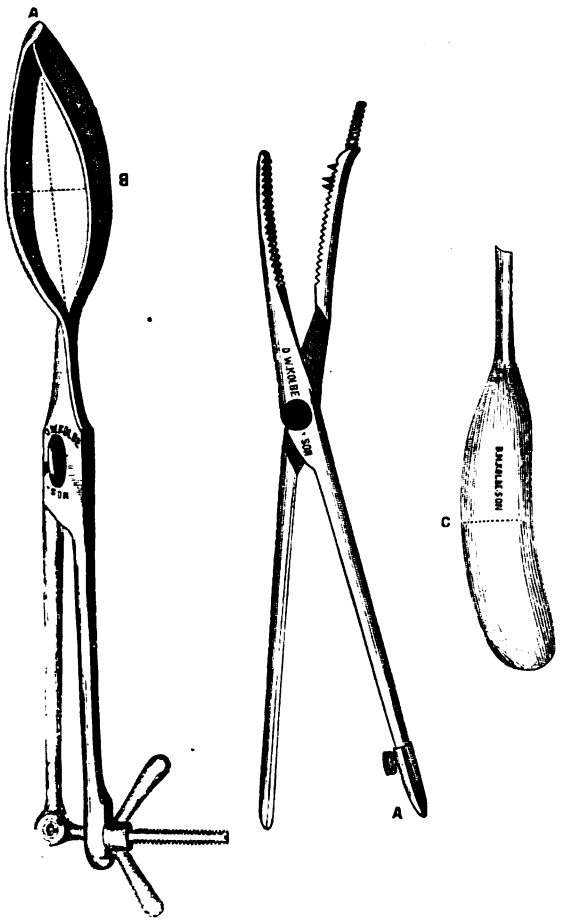
NEW INVENTIONS.

NEW CRANIOTOMY INSTRUMENTS.

BY JOSEPH PRICE, M.D.

THE craniotomy forceps figured below have the following peculiarities: 1. Thin flat blades, one and three-quarter inches wide, to allow easy application in markedly deformed pelves, and the weight principally distributed in the handles. 2. The Hodge angulation for use on the superior strait. 3. The absence of fenestra to increase the strength of the blades for powerful compression and traction, and to allow more ample protection in operative procedure during perforation, etc. 4. A greater cephalic curve, so that the points come in apposition to prevent slipping. 5. A screw on the end of the handles to cause greater compression than could otherwise be exerted.

Another forceps for a similar purpose, one specially intended for effectually crushing the occipital and facial



bones, has one blade (handle) terminating in a flat sharp-pointed perforator; this is covered in use by a leather shield to protect the soft parts during introduction. This shield is not removed, but the perforator cuts through it when it is pressed firmly against the fœtal cranium. The other blade has attached to it a blunt screw, which is intended to be screwed into the spinal canal of the child for aiding traction, and fixation for crushing the occipital and facial bones. This screw is so blunt that damage could hardly be done *even by an inexperienced operator*. Made by Mr. Kolbe, instrument-maker, 1207 Arch Street, Philadelphia.

1317 SPRING GARDEN STREET,
August 14, 1885.

CORRESPONDENCE.

TREATMENT OF THE OPIUM HABIT BY CODEIA.

To the Editor of THE MEDICAL NEWS.

SIR: I desire to call your attention to a remedy for the opium habit. I first commenced the use of this remedy in 1883, and since that time twenty-four cases have been permanently cured under my treatment by the use of this drug. It is codeia, a drug with which all physicians are familiar; but I have known but two members of the profession who were acquainted with the proper method of its use for this trouble. In order to use the remedy properly it is necessary to be thoroughly familiar with the past life of the patient, the length of time opium has been used, and the amount used. To cure the patient of the habit I commence, as a rule, with two grains of codeia three times a day, and increase the dose until the same effect is produced upon the system that is produced by the opium.

After the use of opium has been supplanted by the use of codeia, the system has become accustomed to a drug the use of which can be dispensed with in a very short time. Codeia, when used in this manner, does not block up any of the secretions, and has no other effect upon the stomach than to give the patient a slight increase of appetite. It has a slight tendency to constipate the bowels; and with some it produces an after depression, but not with those who have used opium to any great extent.

Previous to the use of this remedy it was my practice to use coca in certain cases. I found, however, that it constipated the bowels, and took away the appetite; and that, after continued use, it was almost as difficult to get rid of the coca habit as it had been to become relieved from the morphia.

With the use of the remedy some patients must have a tonic treatment; and if constipation exists, I have found the aloin pill, No. 1, to be the best remedy.

Respectfully,
W. H. LINDENBERGER, M.D.

BARTLETT SPRINGS, CALIFORNIA, August 6, 1885.

THE ANATOMICAL BILL.—Success has at last crowned the efforts of the Demonstrators' Association of the State of Illinois. As the result, more particularly of the zeal, industry, and united effort of the members of this Association, "An Act to promote the science of medicine and surgery in the State of Illinois," was passed 24th June, 1885, approved 26th June, 1885, in force 1st July, 1885.

Digitized by Google

The Act provides: I. That superintendents of penitentiaries, houses of correction, and bridewells, wardens of hospitals, insane asylums, and poor-houses, coroners, sheriffs, jailors, city and county undertakers, and all other State, county, town, and city officers in whose custody the body of any deceased person, required to be buried at public expense, shall be, shall give permission to any physician or surgeon (a licentiate of the State Board of Health), or any medical college or school, public or private, of any city, town, or county, upon his or their request therefor to receive and remove free of charge or expense, after having given proper notice to relatives or guardians of the deceased, the bodies of such deceased persons to be buried at public expense, to be by him or them used within the State for advancement of medical science, preference being given to medical colleges or schools, public or private; said bodies to be distributed to and among the same equitably, the number assigned to each being in proportion to the students of each college or school;

Provided, however, that if any person claiming to be and satisfying the proper authorities that he is kindred to the deceased shall ask to have the body for burial, it shall be surrendered for interment; *and provided further*, that any medical college or school, public and private, or any officers of the same, that shall receive the bodies of the deceased persons for the purpose of scientific study, under the provisions of this Act, shall furnish the same to students of medicine and surgery, who may be under their instruction, at a price not exceeding the sum of five dollars for each and every such deceased body so furnished.

II. A sufficient bond that the body or bodies shall be used only for the promotion of medical science within the State must be given, and whosoever shall sell or buy any such body or bodies, or shall traffic in the same, shall be deemed guilty of a misdemeanor, and be subject to fine and imprisonment.

III. The penalty for the officer refusing to deliver the body, etc., is fixed at $50 to $100 for first offence; $100 to $500 for second offence; $500 or more, or imprisonment for six to twelve months, for third offence.

IV. It is the duty of those who receive bodies, to bury or cremate the remains of all bodies after they have answered the purpose of medical science.

V. "An Act to promote the science of medicine and surgery in the State of Illinois," approved 16th February, 1874, in force 1st July, 1874, is hereby repealed (Hurd's Revised Statutes, 1883, pp. 745-746).

The county board, at its session, Monday, 20th July, 1885, issued instructions to the wardens of the county hospital, poor-house, and insane asylum, and to the coroner and county physician, to turn over the unclaimed bodies to any physician, representing a medical college, who would file a bond for $10,000.

The strenuous struggle between the medical men of Chicago and the members of the county board for the possession of the pauper dead has thus been terminated.

APPOINTMENT.—Dr. John E. Owens (Jefferson, 1862) has been elected one of the consulting surgeons to Michael Reese Hospital.

WASHINGTON.

(*From our Special Correspondent.*)

THE NEW ARMY MEDICAL MUSEUM AND LIBRARY BUILDINGS.—Bids were opened at the office of Col. Thomas L. Casey, on Friday, the 7th instant, for the erection of a fire-proof building for the Army Medical Museum and Library. The following were the bidders and total amounts bid, including the heating apparatus: D. C. Weeks & Son, New York, $233,637; Frank Baldwin, Washington, D. C., $185,490; Bright & Humphrey, Washington, D. C., $179,987; August Getz & Co., Washington, D. C., $194,000; M. A. McGowan, Washington, D. C., $182,540.17; C. A. Schneider & Sons, Washington, D. C., $198,405.33; D. J. McCartney & Co., Washton, D. C., $200,595; J. F. McDermott, Washington, D. C., $191,600.

CHICAGO PHYSICIANS AND THE NEW ORGANIZATION OF THE CONGRESS.—Believing that the American Medical Association, at its late meeting in New Orleans, took such action with reference to its Committee appointed one year before, to unite, arrange for, and organize the ninth International Medical Congress, as to nullify in part the work performed by said Committee, thereby jeopardizing the success of the proposed Congress, and putting the medical profession of this country in a false and unfavorable light, the undersigned disapprove of this action of the Association, and decline to serve in the positions to which they have been appointed in the Congress as at present organized.

A. Reeves Jackson, N. Senn,
Henry M. Lyman, Charles T. Parker,
James Nevins Hyde.

CHARLESTON PHYSICIANS AND THE NEW ORGANIZATION.—The undersigned, for reasons connected with the changed circumstances in the organization of the proposed International Congress, since their appointment in the several Sections, hereby respectfully withdraw their names.

Middleton Michel,
F. Peyre Porcher,
Francis L. Parker.

OTHER RESIGNATIONS FROM THE NEW ORGANIZATION.—We are informed that Dr. Edwin M. Snow, of Providence, has declined the Vice-Presidency of the Section of Collective Investigation, Nomenclature, and Vital Statistics, and that Dr. D. Bryson Delavan, of New York, has declined the secretaryship of the Section of Laryngology.

Dr. Thomas F. Wood, of Wilmington, N. C., has declined to serve on the Council of the Section of Practical and Experimental Therapeutics; likewise Drs. J. Rufus Tryon, U. S. N., and Alfred A. Woodhull, U. S. A., on the Council of the Section of Military and Naval Surgery and Medicine; and Dr. Christian Fenger on the Council of the Section of Pathology.

A GERMAN OPINION ON THE CONGRESS ORGANIZATION.—The International Medical Congress, to be held in Washington in 1887, is in great danger, if not of being totally wrecked, of at least losing those characteristics without which such gatherings would degenerate into insignificant meetings.

Digitized by Google

We have, heretofore, pointed out that the preparations for the Congress, under the direction of the Secretary-General John S. Billings, were progressing most satisfactorily. The officers, the members of the General Committee, and of the Executive Committee, the presidents, secretaries, and councillors of Sections, appeared to us to have been selected with remarkable skill, and we missed scarcely a name which is well known and held in esteem in Europe. In addition to the great American Medical Association the regularly organized State and local medical societies, as well as those which were devoted to special subjects, were in our opinion entitled to representation.

The hopes which were based on such an arrangement as was proposed are, in an entirely incomprehensible manner, destroyed by the American Medical Association, and permanently so, unless a remedy is very speedily found.

The original committee, with Austin Flint as President and J. S. Billings as Secretary-General, proceeded in full accordance with the principles of former congresses, and in comformity with the understanding with which the Congress at Copenhagen accepted the invitation to America—to wit, that the professional status of the United States in the Congress should be represented in its entirety as a national body, which should include all medical societies and bodies with common and special aims. The American Medical Association concluded otherwise. By it the invitation was construed in a different sense, but in Copenhagen it was universally understood as coming from the profession of the United States, and so did Dr. Billings and his associates understand it.

The American Medical Association put no such interpretation upon it, and instead of feeling concern for the success of the International Medical Congress, it allowed itself to be influenced by merely selfish motives. At its meeting held this year at New Orleans, it annulled all that the committee had brought about by its remarkable energy. Secretary-General Billings warned them in vain, and explained the correct relation of the profession of the United States to the International Congress. The entire programme, prepared with so much difficulty, was thrust aside, thirty-four members added by specific authority by the original committee were stricken off, and thirty-eight new members of the committee were appointed. The ruling idea was to bring the International Congress completely under the leadership and authority of the American Medical Association, and to elect additional members of the committee; not because of their ability, but because they came from the several States and Territories. It was decided, in a word, that the Congress should be a gathering of the American Medical Association, with a somewhat greater number of foreign guests than could otherwise be invited.

The motives of those opposing the excellent original committee appeared to spring from injured ambition, which had not received recognition. They had long assumed a threatening attitude, and were anxious to reap the fruits of their underhand work.

Accordingly, an old controversy was utilized, which has divided the physicians of the United States into two factions, distinguished as the old code and the new, differing from each other in that one observes the strictest, the other a lax attitude in reference to consultations with irregular practitioners. Now, a number of the followers of the new code were selected as members of the various committees, and their opinion on the code question was held by the Association to be sufficient ground to exclude them. Whatever may be thought of the question of professional ethics in America, the American Medical Association was not justified in making this a criterion for membership in the International Medical Congress, whose whole character must always remain entirely uninfluenced by such local differences.

Because the opponents of the original committee had a majority in New Orleans, the new committee chosen was called together on the 24th of June at Chicago, and its meeting conducted in the interests of the majority. This procedure excited public opinion in the United States in the highest degree. The formal right of the American Medical Association thus to act is questionable, so that nothing remained except for the leaders of the North American profession to deny responsibility for such a procedure, and at the same time to refuse to participate therein. This was done unanimously.

The most eminent physicians of Philadelphia, Boston, and Baltimore have refused office in the new organization, and the same action is expected on the part of the physicians of other cities. Of how little real importance the code question is in this matter may be inferred from the action of the medical profession of Philadelphia, whose members are thoroughly in accord with the principles of the old code, and yet were the first to protest against the action of the American Medical Association.

Whatever may be thought of the value of international scientific and medical congresses, it is certain that the European profession this time would willingly have availed themselves of the invitation of their colleagues in the United States. This, certainly, we can affirm of Germany. As the matter now stands, one may fairly hesitate to attend, since a local result only can be attained. With many there will be little inclination to take part in a Congress to which the 40,000 physicians of the United States are not admitted, but only a small minority of them, inasmuch as the American Medical Association in all its branches numbers only 3000 members. We were well pleased to act under the leadership of Austin Flint and Billings, but we have little confidence in that of Shoemaker, who is merely known to us through his oleates. — *Deutsche medicinische Wochenschrift.*

A FRENCH OPINION ON THE CONGRESS ORGANIZATION. —We learn from the *Medical Times* that the organization of the International Medical Congress, to be held at Washington, has met with difficulties with our brothers beyond the sea. The American Medical Association does not approve of the acts of the Committee named at Copenhagen. although it contains a large majority of its own members. It desires to replace the Committee by another, chosen entirely from its own membership.

We do not wish to criticise the American Medical Association, but it is undeniable that this method of procedure is contrary to that hitherto followed in the organization of the International Medical Congresses, and, as the *Times* justly says, runs the risk of compromising the success of the International meetings in the

Digitized by Google

future. What is not less certain, and not less serious, is, that many American members, who in this country are held in the highest esteem, are estranged from the Congress. Now, if the hope of extending the circle of our acquaintance and of forming new ties is a powerful attraction for us, we will be not the less happy to see again those whose names have been long known to us, and whom we are proud to call our friends. There is no doubt that what disaffects them will cool the ardor of their colleagues in the Old World too much to allow them to trust themselves to the uncertainties of an ocean voyage. We have hopes, however, that our American colleagues will see that the Association does not lose sight of the objects for which the International Congress was originated, and that we shall yet find at Washington a branch of the ancient tree bearing, under a new sun, fruits the more beautiful, because fertilized by fraternal love and the spirit of reconciliation.—*Le Progrès Médical.*

BRITISH OPINIONS ON THE CONGRESS ORGANIZATION.—There is something very ludicrous in the attitude of the Committee appointed by the American Medical Association, and which, on its own authority alone, presumed to undo the work already accomplished by the Committee specially appointed by the Congress at Copenhagen. The former self-constituted body has deposed the well-known and respected physicians elected by the latter to preside in the various Sections, many of whose names are of world-wide renown, and replaced them by a long string of nonentities, scarcely one of whom has ever been heard of outside the village in which he gains a living. The few celebrated physicians who were graciously permitted to retain official posts have naturally and properly shown their disgust by declining to be associated with the strangely mixed representatives of American medical science who are elevated into notoriety by the action of the Association ring; and things are now at such a pass that even the home journals are reckoning up the meeting as certain to be a miserable failure. The more sensible organs, however, are tendering the male-contents a piece of advice which they will do well to act upon, namely, that at their next meeting they should quietly determine their official existence, and resign the organization of the Congress to men of standing in the profession, and who will be able to command confidence and respect on this side of the Atlantic. Unless some definite action of this kind is speedily taken, it is a moral certainty that the Congress, if persisted in, will lose every atom of its international character; for no one is going to contribute papers, or be at the expense of reading them to an assembly of mutual admirationists, whose meddlesome conceit is scarcely equalled by their obscurity in the world of medicine. We have still, however, sufficient faith in the good sense of our American *confrères* as a whole, to feel assured that the little band of nobodies will speedily be sent to the rightabout, and the direction of the arrangements reassumed by the men who ought never to have resigned the trust reposed in them.—*Dublin Medical Press.*

The Boston Medical and Surgical Journal publishes the following letter from Sir William MacCormac, Secretary-General of the London Congress of 1881:

"I have seen in medical papers, and heard through private sources, that a serious disagreement has occurred in respect to the organization of the ensuing International Congress in Washington. A few of those who had been concerned in organizing the London Congress, recently met to talk the matter over, for we feel that any failure which might attend the Congress in the United States would be little short of a professional disaster. I do not myself think, and most here would share my opinion, that a congress from whose ranks some of your best physicians and surgeons have determined to withdraw, and whose members are to be further restricted to such as belong either directly or by affiliation to one medical body in America, would be likely to be attended by many colleagues from this country.

"Speaking from personal knowledge, an International Congress cannot be a success, unless taken up in the warmest and most self-sacrificing manner by all the principal men in the country where it is to be held. I was present at the meeting in Copenhagen, where the invitation to meet in America in 1887 was given, and after some discussion accepted. I am sure it was present to the mind of every one there, that the invitation was one from the profession of America, and not from any section of it, or any particular medical society in it. Otherwise I feel pretty certain Professor Virchow's invitation to meet on the next occasion in Berlin would have been accepted.

"Even now, it would appear to me wiser to have that invitation renewed, or to meet in some other place than to have a meeting in America, from which, so far as we may at present judge, many of the chief men on both sides of the Atlantic would absent themselves."

AMERICAN OPINIONS ON THE CONGRESS ORGANIZATION.—Place the blame where we may, either with the original committee, the American Medical Association, the new committee, or the disaffected members of the profession throughout the United States, we can but acknowledge that the arrangements for the meeting of the International Medical Congress are, upon the whole, in a very bad fix; that the prospect for a successful Congress is very much threatened; and that the medical profession of the United States does not present a very enviable aspect to the outside world.—*Texas Courier-Record of Medicine.*

Died of an overdose of reconstruction! A good epitaph for a dead Congress.—*Louisville Medical News.*

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION was held at Cardiff on the 28th, 29th, 30th, and 31st of July, under the Presidency of Dr. W. T. Edwards, of Cardiff.

Dr. W. Roberts, of Manchester, delivered the Address in Therapeutics, which was largely devoted to the consideration of questions of diet in disease. After referring at some length to the food customs of Great Britain, and their effects on different constitutions, Dr. Roberts continued: "In a considerable number of conditions, our patients are unable to take solid food, and are reduced to the necessity of using food which can be administered in the liquid form. This is usually the case in the febrile state and in serious organic disease, especially of the abdominal organs, and in the terminal stages of almost all diseases. There are other conditions in which, although the patient may have the ability to take solid

Digitized by Google

food, it is not desirable that such food should be administered to him. In narrowing of the pylorus or other part of the digestive tract, in ulceration of the intestinal mucous membrane, it is obviously undesirable to administer articles of food which are capable of forming lumps or masses which may block up the narrowed parts of the intestinal tube, or irritate the ulcerated surfaces. There is thus a large field for the employment of liquid food; and one of the most embarrassing tasks in clinical dietetics is to devise food in this form in sufficient change and variety, and having at the same time an adequate nutritive value. Our resources in this state of things consist of milk, beef-tea, and other meat decoctions, cold-made meat infusions, raw eggs, and the various gruels." He then spoke of the dietetic values of milk, beef-tea, and other meat decoctions, eggs, fortified gruels, and concluded as follows: "A matter of interest, in designing food for the sick-room and nursery, is the consideration of the special properties of the several kinds of cereal and leguminous substances used as food. In point of chemical composition, the several kinds of cereal grains are closely allied; still there are differences between them, and these differences may be of importance. The proteid of wheat is not quite identical with that of oats or barley. On the other hand, leguminous seeds differ importantly in composition from the cereal grains. Taking the lentil as a type of the leguminous group, it is to be observed that lentil flour contains twice as much proteid matter as wheat or oat flour, and almost twice as much lime. Moreover, the proteid of the leguminous seeds differs materially from that of wheat or oats. These differences are probably of not a little importance in feeding the sick and the young; and, if we had more knowledge and experience in their use, we could, perhaps, utilize with advantage these several cereal and leguminous products, and combine them in varied ways to meet the indications and necessities of different cases.

The invitation to hold the meeting of 1886 at Brighton was accepted, and Dr. Withers Moore, of Brighton, was chosen President-elect.—*The Lancet*, August 1, 1885.

GOOD HEALTH RESULTS FROM SANITARY WORK.—Sanitary authorities have claimed that the sanitary work which they have recommended to be done as a preparation for cholera—such as preventing and abating nuisances, attending to drains, sewers, privies, and cesspools, cleaning up generally, and unusual carefulness in regard to foods and drinks—would reduce the sickness and deaths from other diseases, even if cholera did not come. The weekly reports for July, 1885, to the Michigan State Board of Health by physicians in different parts of the State, indicate that this claim is being realized in Michigan, so far as relates to lessened sickness—it having been lessened from nearly every disease, and greatly lessened from fevers and from diarrhœa, and other diseases believed to be especially influenced by sanitary conditions; and this is true, notwithstanding the meteorological conditions in that month were rather more than usually unfavorable to health. It is proper to state, however, that the sickness in any month is influenced by the meteorological conditions in the preceding month, and that the meteorological conditions in June, 1885, were unfavorable to health.

Observations in Michigan for many years have shown that, in July, the meteorological conditions especially unfavorable to health are: High temperature, excessive humidity of the atmosphere, and deficiency of ozone. The bulletin of *Health in Michigan*, July, 1885, says: "For the month of July, 1885, compared with the average of corresponding months for the seven years—1879–1885—the temperature was slightly higher, the absolute and the relative humidity were more, and the day and the night ozone were less.

"Compared with the average for the months of July, in the seven years—1879–1885—remittent fever, intermittent fever, dysentery, consumption of lungs, cholera infantum, diarrhœa, cholera morbus, measles, and whooping-cough were less prevalent in July, 1885."

A large part of this decrease in sickness has undoubtedly been due to the medical and sanitary journals and the newspapers, which have constantly kept before the people the necessity for sanitary work, and the facts as to the spread of cholera in Europe.

It remains to be seen to what extent efforts for the exclusion of cholera from this country, and the general preparation for cholera, by boards of health and the people, shall prove effectual; but, even if cholera shall not be entirely prevented, there will remain the belief that the measures which have so greatly decreased the sickness from other diseases cannot but have had their influence in decreasing it; and, if cholera does not occur in this country, it proves quite probable that, by reason of the suffering elsewhere, there may be as many cases of serious sickness prevented in this country as there have been cases of cholera in Europe. But this may not continue without continued vigilance and effort.

INSPECTION OF EMIGRANTS.—From reports received by the Marine-Hospital Service, it appears that the sanitary inspectors are more vigilant than ever before. Many emigrants are returned to the shore for lack of proper papers; and, in cases where they have come from infected districts, they are detained, and their baggage thoroughly disinfected, after which they are allowed to sail. No objection has been made to the practice by any foreign power, except France; and, notwithstanding her objections, since the recent outbreak of cholera was reported from Marseilles, the inspection at Havre was recognized.

ABOUT VESSELS FROM INFECTED PORTS ARRIVING AT PHILADELPHIA.—The following resolution was adopted this week by the Board of Health of Philadelphia:

Resolved, That all incoming vessels bound for the port of Philadelphia, from ports infected, or which may hereafter become so, including at present the Mediterranean and Portuguese Ports, and also all vessels which have or have had sickness on board since leaving the port of departure, shall be required to report at the United States Quarantine Station at the Delaware Breakwater, and that all pilots in charge of such vessels be and are hereby required to obey this order, under penalty of the law, before bringing such vessels into the Philadelphia Quarantine Station on the Delaware River.

YELLOW FEVER AT VERA CRUZ.—Vera Cruz is again suffering from yellow fever in an aggravated form. The

Digitized by Google

consul at that port applied to the State Department for an inspector; but, inasmuch as the fact is generally known that Vera Cruz is afflicted with yellow fever, health officers throughout the country view with suspicion all vessels arriving from that port, and treat them accordingly.

SMALLPOX EPIDEMIC IN MONTREAL.—The President of the Board of Health of Montreal has declared that smallpox is epidemic in that city. The City Hospital contains thirty-six patients, and a new wing is in progress of erection which will hold fifty more patients. It is not known how many are suffering from the disease in private dwellings.

The State Department has transmitted to the Secretary of the Treasury a communication from the Governor of Michigan to the effect that smallpox is prevailing to an alarming extent at Montreal, and suggesting that measures be taken immediately to prevent its introduction into the United States.

THE AMERICAN DERMATOLOGICAL SOCIETY will hold its ninth annual meeting under the Presidency of Doctor William A. Hardaway, of St. Louis, at Greenwich, Connecticut, on Tuesday, September 1st.

HONORS TO SIR JAMES PAGET.—The Royal College of Surgeons of England, at its meeting held on August 6, by a unanimous vote, in view of his many important services to the College, requested Sir James Paget to sit for a marble bust, to be executed at the expense of the College, and to be placed in some suitable position in the College buildings.

Mr. Hutchinson then gave notice of motion:

"That a committee be appointed to consider the practicability of adding a clinical wing to the Hunterian Museum, to be associated with the name of Paget, and to have for its especial, but not exclusive, object the display of casts, photographs, drawings, etc., illustrating the results of disease and injury in the living subject."

DR. GUSTAV BURGE has been invited to the Chair of Physiological Chemistry at the University of Basle.

NOTES AND QUERIES.

MERCURIAL TABLETS.

To the Editor of THE MEDICAL NEWS.

SIR: Permit me to call attention to the improved form of the mercurial tablets described in THE MEDICAL NEWS of December 27, 1884. They were first made without color, containing 7.3 grs. hydrarg. chlor. corros., and 7.7 grs. ammonium chlor., merely arbitrary quantities adopted for convenience in making solutions of a standard strength and of given quantity. As the tablets were similar in form and color to the ordinary tablets composed of innocuous preparations now so much in vogue, it was deemed best, on account of the dangerous character of these tablets, to give them a specific color, as an additional safeguard against possible accidents through carelessness in their use. This has been accomplished by the addition of one-fiftieth of a grain of C. P. green aniline. When the tablet is dissolved, this gives the solution a dark-green color. The chemical qualities are not altered by the addition of the aniline, and it does not interfere with the germicide power of the mercuric chloride. Aniline as a coloring matter is to be preferred to permanganate of potassa because it gives a more stable color. The latter resembles in color many harmless drugs, whilst the green color of the former serves as a danger signal to professional gentlemen and the laity alike.

Yours respectfully,

CHARLES MEIGS WILSON.

1517 WALNUT STREET, August 18, 1885.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 11, 1885, TO AUGUST 17, 1885.

CAMPBELL, JOHN, *Colonel and Surgeon.*—Granted leave of absence for one month.—*S. O. 184, A. G. O.*, August 13, 1885.

IVES, FRANCIS J., *First Lieutenant and Assistant Surgeon* (recently appointed).—Ordered for duty in Department of the Platte.—*S. O. 184, A. G. O.*, August 13, 1885.

WOLVERTON, W. D., *Major and Surgeon.*—Granted leave of absence for twenty days.—*Washington Barracks, D. C., S. O. 171 Department of the East*, August 14, 1885.

MAUS, L. M., *Captain and Assistant Surgeon.*—In addition to his other duties, assigned to duty as Attending Surgeon of the Department Rifle Camp.—*S. O. 83, Department of Dakota*, August 3, 1885.

CHAPIN, A. R., *First Lieutenant and Assistant Surgeon.*—Granted one month's leave, to take effect when services can be spared by Commanding General of Department of Missouri, with permission to apply for one month's extension.—*S. O. 179, A. G. O.*, August 6, 1885.

WALES, PHILIP G., *First Lieutenant and Assistant Surgeon* (Fort Cœur d'Alene, Idaho).—Ordered for temporary duty at Boise Barracks, Idaho.—*S. O. 130, Department of Colorado*, August 1, 1885.

APPOINTMENT.

KENDALL, WILLIAM P.—To be Assistant Surgeon U. S. Army, with the rank of First Lieutenant, to date from August 12, 1885.—*S. G. 181, A. G. O.*, Aug. 10, 1885.

AZFULL, THOMAS F., *Captain and Assistant Surgeon.*—Retired from active service August 10, 1885.—*S. O. 191, A. G. O.*, Aug. 10, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING AUGUST 15, 1885.

BEYER, H. G., *Passed Assistant Surgeon.*—To attend meeting of the American Association for Advancement of Sciences at Ann Harbor, Michigan, and at conclusion of meeting to resume duty at the Smithsonian Institute.

BOYD, JOHN C., *Passed Assistant Surgeon.*—From navy yard, Washington, D. C., to special duty at Bureau of Medicine and Surgery, Washington, Navy Department.

LIPPINCOTT, J. C., *Passed Assistant Surgeon.*—To navy yard, Washington, D. C., as relief of Passed Assistant Surgeon Boyd.

OWENS, THOMAS, *Assistant Surgeon.*—From special duty at Bureau of Medicine and Surgery, Navy Department, and waiting orders.

SAYRE, J. S., *Assistant Surgeon.*—From U. S. R. S. "Independence" to Naval Hospital, Mare Island, California.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING AUGUST 15, 1885.

BAILHACHE, P. H., *Surgeon.*—To proceed to Delaware Breakwater Quarantine as Inspector, August 15, 1885.

STONER, GEORGE W., *Surgeon.*—Granted leave of absence for thirty days, August 10, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

ORIGINAL LECTURES.

ON THE OPERATION FOR STRANGULATED HERNIA.

BY PROFESSOR VERNEUIL.

A Clinical Lecture delivered at the Hopital de la Pitié, July 6, 1885.

(Reported by W. W. SKINNER, M.D., EXTERNE DE HOPITAUX.)

I WISH to speak to you to-day, gentlemen, upon the appreciation of the opportunity for operating in cases of strangulated hernia. The patient you have just seen in one of the wards, and who has recently undergone the operation of kelotomy, furnishes me a fitting occasion to present to you this subject.

If the strangulation of the hernia be sometimes difficult to diagnosticate, there are other occasions in which doubt is not permissible, and the presence of a constriction is most evident. Even in these cases the indications and contraindications of operation are often difficult to seize. Nothing was more doubtful, formerly; but, thanks to the definite rules resulting from the experience of surgeons of our epoch, nothing is clearer to-day.

No longer than twenty years ago, before the indications for the operation were clearly enunciated, and before such treatment of the operation-wound was practised as is done at present, the mortality after operations was considerable. When I was surgeon at the Hôtel-Dieu I was frightened at the great proportion of the resulting deaths. One-half of the cases were fatal.

The principal causes of this fearful mortality may be reduced to three: 1st, the inordinate and ill-timed employment of *taxis;* 2d, *absurd therapeutics;* and 3d, *tardiness* in operating, because every lesion of the peritoneum is fraught with more or less danger; and, when this lesion is made on an inflamed or damaged peritoneum, the results are far more fatal.

In principle, I am not opposed to taxis, properly performed at the proper time; but taxis, practised beyond all reason, is an injurious manœuvre. On the contrary, it is very frequently efficacious when performed at a seasonable time. It is also extremely essential that taxis be *intelligently* performed. Some surgeons imagine that, by pushing very hard upon the hernia, they can cause its reduction. That, however, is a most detestable practice, and the dangers to which the patient is thereby exposed are formidable. Among these dangers may be named the rupture of the intestines, and the reduction of the hernia *en masse*. If taxis, exercised with moderate force, does not succeed, that method of reduction should be abandoned.

Secondly, an absurd treatment is often the cause of want of success in the subsequent operation. The patient is frequently made to swallow warm infusions, in the hope of causing the hernia to disappear. He is repeatedly purged, or aromatic frictions are prescribed, or he is subjected to enemata of tobacco, and other ineffectual means, which cost the patient loss of time and strength.

Finally, after having vainly tried this medical treatment, the services of the surgeon are at last requested, the patient being *in extremis*. But, notwithstanding the best directed efforts of the most skilled operators, the results in these conditions are too often fatal. His attempts are struck with inutility. In some cases, however, a rare success crowns the operation. If the surgeon does not deem it advisable to operate, he should prescribe opium, belladonna, and ice. Patients have been put in great danger by operations performed inopportunely.

Why, therefore, so much delay? It is easy to understand that in former times, when the operation was followed by death in fifty per cent. of the cases, there was much reason for hesitation before exposing the sufferer to a new danger, but since that time kelotomy has become a benign operation. It has even become an elective process. It goes without saying that the operation should be performed under the best conditions, according to the rules of modern surgeons and the principles of antisepsis. I would prefer a puncture of the bladder, or an internal urethrotomy, to a catheterism badly done. So, kelotomy, if done unskilfully, and without proper precaution, is an exceedingly dangerous operation.

The patient in our ward has carried a left inguinal hernia during eighteen years. It was an antero-epiplocele; that is to say, a tumor formed by a loop of intestine and a portion of the greater omentum protruding outside of the abdominal cavity. It is necessary that you should know that the presence of the omentum is an advantage in a hernia. It prevents too great a pressure upon the intestine by interposing its mass between this viscus and the hernial sac, and thus permits greater mobility of the engaged intestine. On the other hand, the presence of the epiploon is an obstacle to the easy reduction of the hernia; and in this case it is of the highest importance that the surgeon should be endowed with the *doigt chirurgical*, in order to be able to decide by the touch in which part of the tumor is the intestine, so that taxis may be intelligently and usefully applied.

In the present case taxis was unsuccessfully tried, and it became necessary to open the sac; after which the stricture was divided, and the intestine and walls of the sac washed with antiseptic solutions. The loop of intestine was then returned to the abdominal cavity, while the omentum was excised, and the bleeding vessels tied with carbolized catgut.

A question naturally arises here concerning the surgeon's conduct in cases of antero-epiplocele, which he has decided to operate. Shall the portion of omentum in the hernia be returned with the intestine, or shall it be resected? Permit me to lay before you the rules which guide me in such circumstances. If the strangu-

Digitized by Google

lation has existed for a few hours only, twelve hours at the utmost, I reduce the omentum as well as the intestine, especially if the protruding part be in a fair state, yellow, uncongested, and, above all, if it be small; otherwise I never reduce it, but tie the constricted part and resect. If the pedicle is small, tie it in mass with one ligature; if it is large and thick, divide the pedicle in several parts by as many ligatures. The material of which these ligatures should be composed is not indifferent, and, although I do not employ catgut very much, yet it is here necessary, as it is absorbed after being left in the abdominal cavity.

What is to be done with the sac? If its extirpation is not too difficult it may be attempted, the freshened surfaces being brought together and securely sutured. Further, it has been said that this method prevents the reproduction of the hernia in the same place. But too much has been spoken and written about the radical cure of hernia, and operations designed for this purpose have most often failed. My treatment of the incision is very simple; I have always succeeded well in leaving the wound open, but dressed very carefully, with every attention paid to antisepsis. I place upon the wound a piece of collodionized goldbeater's skin, under which the serosity escapes. Over this are laid several thicknesses of gauze, containing powdered iodoform, or else dipped in a solution of carbolic acid. A light impervious tissue, and a bandage well applied, complete the dressing.

The treatment of hernia may be thus announced *en résumé*. Attempts at reduction by taxis during the first twenty-four hours after strangulation. Warm baths and chloroform are useful adjuvants. Later than this, the bistoury. The operation should be performed, and the after-treatment conducted according to the best antiseptic principles. If there is a suspicion of gangrene of the intestine, leave it outside of the abdominal cavity; but, when it is in a good state, replace it. Reunite the serous walls of the sac, and upon the open wound place a flat dressing, similar to the one I have described.

One word, gentlemen, concerning a case of hernial abscess, before operating upon it. The patient is a student of medicine, who presents an acute abscess near the margin of the anus on the left side. The abscess has already burst several days ago; but pain, redness, and swelling still persist, and the healing is no further advanced than when the pus was first discharged. When you have an acute abscess in this region, let me advise you to perform immediately the operation for *fistula in ano*. Sometimes, it is true, ordinary dressings and a treatment less active suffice; but, generally, you will be obliged to have recourse to the above-mentioned operation, which should be performed early, as it is useless to let your patient suffer for weeks, and finally be forced to undergo the radical treatment after all.

[Professor Verneuil then caused the patient to be chloroformed. Anæsthesia being complete, the nates of the patient were drawn to the edge of the table, and he was held by aids in the position for lithotomy. The Professor then passed a grooved director into the opening at the summit of the abscess, pierced the rectum, and brought the end of the instrument out at the anus. The tissues lying upon the director were then divided by Paquelin's thermo-cautery, and a carbolized dressing applied.]

ORIGINAL ARTICLES.

THE KOCH COMMA-BACILLUS AND ITS RELATION TO ASIATIC CHOLERA.

BY HERMANN M. BIGGS, M.D.,
INSTRUCTOR IN THE CARNEGIE LABORATORY, N. Y.

ALTHOUGH many articles have appeared within the last few months, in the different American medical journals, on the subject of cholera, there are some important points with regard to the comma-bacillus and its relation to the disease that have not been clearly brought out, and the present status of the cholera bacillus has not been defined in any of the recent papers on this subject. During the last few months the writer has given considerable time and attention to the cultivation and study of three of the comma-bacilli, and this together with the facts mentioned above have been considered a sufficient excuse for the presentation of the present article.

The interest aroused in this subject among medical men by the announcement of Koch, and the outbreak of the disease in Europe attracted many investigators to the study of the cholera bacillus, and many contributions have been made to our knowledge of the etiology of the disease. But the results reached by different observers on the same questions have in many cases been directly contradictory to each other on every important point, so that much confusion has resulted.

It is necessary, in the first place, to understand clearly Koch's conclusions as to the comma-bacillus described by him.

These are briefly as follows:

1. Peculiar microörganisms are found in the mucous flakes and rice-water discharges of all persons suffering from Asiatic cholera, which from their peculiar form Koch calls "comma-bacilli."

2. These bacilli are about ½ or at most ⅔ the length of the well-known tubercle bacillus, and are of about the same thickness. They are very active in their movements, are always more or less curved, and vary in length according to the state of their growth. They occur singly or in pairs, and sometimes form longer or shorter wavy lines composed of many individuals.

3. These comma-bacilli are found post mortem almost as pure cultures in the lower part of the ileum, to the exclusion of other microörganisms. They also occur in the mucous membrane of the ileum, especially in the vicinity of the lymph glands and lymph follicles.

4. They bear a constant relation to the course and severity of the disease in each case, and disappear with the cessation of the acute processes.

5. In typical and rapid cases the mucous membrane of the lower part of the ileum exhibits characteristic alterations, *i. e.* loosening and detachment of the epithelium, and swelling and congestion of the bloodvessels, often accompanied by extravasation of blood into the tissue. It is probable that these lesions are caused by the penetration, growth, and multiplication of the comma-bacilli in these tissues, and that the morbid processes constituting the disease are brought about by the production by these germs of a

Digitized by Google

special chemical poison, and its absorption by the system.

6. No microörganisms are found in the blood or other tissues.

7. These germs grow well in ordinary neutral and slightly alkaline culture media at the temperature of the room, and show certain peculiarities of growth in different culture media, by which they can with certainty be distinguished from all other germs.

8. The comma-bacilli are killed by acids, by drying, and by various antiseptics. They also soon disappear from a fluid which contains putrefactive microörganisms.

9. Because of their constant occurrence in the intestines of cholera patients, their absence under all other conditions, and the ease with which their presence can be determined, by the peculiar manner of growth and development of the colonies in different culture media, together with certain other characteristics, Koch claims for these comma-bacilli great *diagnostic* value, and an essential *causal* relation to Asiatic cholera.

It is necessary that the morphological and biological peculiarities of this germ should be carefully studied, since it is largely upon these grounds that the assumption rests of the causal relation of the germ to the disease. Of those peculiarities especially worthy of note, the following are the most characteristic. The comma-bacilli are less straight than other bacilli, and are a little curved, similar to a comma. The curving may extend so far that the rod assumes almost the form of a half circle. In pure cultures the rods sometimes present an S-form figure or the form of longer or shorter wavy lines. The S-forms are made up of two individuals, the lines of a large number of bacilli. They are aërobic, requiring the presence of air for their development.

Their growth in nutrient gelatine[1] is peculiarly characteristic. In this the comma-bacilli form colorless colonies, which are at first circumscribed and appear as if formed of strongly refracting bits of broken glass. They liquefy the gelatine. From the peculiar appearances of the colonies in different culture media, they can with certainty be distinguished from all other germs, and can be easily isolated.

In the report of the German Cholera Commission from India, Koch says "in the contents of the intestines of a large number of persons dead of cholera and in the stools of many others sick with the disease, these bacilli have been found in every case. In the intestines of many other persons suffering from or dead of diarrhœa, dysentery, etc., which have been examined, they have never been found, nor do they occur in the stools of healthy persons or those caring for cholera patients or under any other condition. These observations are entirely confirmatory of many similar ones made in Egypt, and from them it is concluded that this comma-bacillus is quite characteristic of and peculiar to cholera."

"That this is, in fact, the case, also, other circumstances go to prove in a most unmistakable manner. First of all, stands the relation of the bacilli to the progress of the disease. They are only found in that organ which is the seat of the disease; namely, the intestine. In the vomited matters only twice have they been detected, and in both these cases the appearances and the alkaline reaction of the vomited matters showed that the bacteria with the contents of the intestines had passed into the stomach. In the intestines they deposit themselves in the following manner: Only few cholera bacilli are found in the first evacuations from the intestines, while they still have a feculent character; but in the watery odorless dejections that follow, the bacilli are present in larger numbers, while at the same time all other bacteria almost entirely disappear, so that in this stage of the disease nearly pure cultures of the comma-bacilli are found in the intestines. As soon as the dejections become again feculent in character, the cholera germs entirely disappear, and after the disappearance of the disease are not to be found at all. The comma-bacilli do not appear in the stomach. The conditions found in the intestine post mortem depend upon the stage of the disease at which death occurs. In the freshest cases in which the intestines present a diffused bright-red color the mucous membrane is still free from hemorrhages, and the contents of the intestines consist of a whitish odorless fluid. In this, almost pure cultures of the cholera germ are found in enormous numbers. The extent of their diffusion corresponds very closely to the intensity and extent of the inflammation of the intestinal mucous membrane. In the upper part of the small intestine there are but few, and they increase in number as the lower part is reached. When death occurs later in the course of the disease, lesions of a significant character are found. The mucous membrane of the small intestines is of a dark-red color, and in its lower portion are found extensive extravasations of blood, and often the superficial layer is necrosed. The contents of the intestine are more or less colored with blood and of putrid and stinking character, owing to the reappearance of bacteria of putrefaction. In this stage the comma-bacilli always diminish greatly in number, but they are found in moderately large quantities in the follicles of Lieberkühn and in their surroundings. This condition, namely, the presence of this peculiar bacteria in the walls of the intestines, was first observed in the Egyptian cholera cases. The comma-bacilli are only completely wanting in the intestines in those cases when death occurs from the supervention of some other disease after the cholera affection has entirely disappeared."

The cholera bacilli conduct themselves as all other pathogenic organisms. They are present exclusively in their own specific disease, and their first appearance coincides with the commencement of the disease. They increase in numbers in proportion to the development in the disease processes and disappear again with their decline. Their situation corresponds to the extent of the lesions found post-mortem, and their numbers bear so significant a relation to the intensity of the affection, that the destructive lesions of the intestinal mucous membrane are through this explained.

[1] Nutrient gelatine is the culture medium most generally useful. It is composed essentially of beef bouillon to which from 1 to 2 per cent. peptone is added, and sufficient gelatine (5 to 10 per cent.) to make it solid.

Digitized by Google

In order to demonstrate the causal relation of the germ to the disease, it is further exceedingly desirable that cholera should be produced artificially in some animals, by the introduction of pure cultures of the bacilli into the intestinal canal. This has been done, but the results have not been altogether satisfactory. The experiments will be given more in detail later in the course of this paper.

There are other peculiarities of this germ which are in harmony with what is known of the etiology of cholera, and serve to strengthen the conclusion that these bacilli are the cause of cholera. Especially worthy of note is the observation that the bacilli are found to have increased in enormous numbers on the clothing of cholera patients which has been soiled by the dejecta, and has been kept in a moist condition for twenty-four hours. This observation affords an explanation for the well-known fact that the clothing from cholera patients is so often the source of infection.

Another important peculiarity is, that the germs are found to be quickly killed by drying. Ordinarily, remaining three hours in a dried condition is sufficient to destroy completely all life. Further, their growth only occurs in neutral or alkaline media. They are killed by acids in weak solution, and the presence of the smallest quantity will entirely prevent their development. They are destroyed in the normal stomach, and are not found either in the stomach or intestines of animals fed upon material containing cholera bacilli. This last peculiarity together with their slight resistance to drying, affords an explanation of the daily observation, that infection so seldom follows direct contact with the sick. In order to produce cholera the bacilli must pass through the stomach unharmed and find their way into the intestines. It is probable that the bacilli can pass through the stomach unaffected if the stomach digestion is disordered. Certain facts observed in all cholera epidemics, and especially in India, seem to favor this view. It has been repeatedly noted, that very often those persons contract the disease who are suffering from indigestion or some disorder of the alimentary canal.

These comma-bacilli, moreover, are easily destroyed by putrefactive microörganisms, and if placed in fluids containing decomposing organic matter, have entirely disappeared after from twenty-four to forty-eight hours. Under the most favorable conditions they live but comparatively a short time in the human alimentary canal, and have, as a rule, entirely disappeared after six days from the commencement of the disease.

Since Koch's announcement, three important comma-bacilli have been described, all of which resemble so closely the Koch comma-bacillus in their morphological appearances, that they can only with difficulty be distinguished from it on these grounds alone.

Much confusion has arisen and is constantly arising from the want of sufficient recognition on the part of many observers, of the fact, that similarity in morphological appearances does not by any means prove the identity of two germs. To establish this, it is quite as essential that there should be a similarity in the growth and development of the colonies in different culture media, and also an identity in function. Owing to a neglect to recognize sufficiently this fact, much of the work of the English Cholera Commission has been rendered practically valueless.

The first of these three comma-bacilli was discovered by Finkler and Pryor, of Bonn, in the stools of a person suffering from simple or sporadic cholera. This bacillus they isolated and cultivated in different culture media, and stated that it was identical with the comma-bacillus described by Koch. Cultures of this microbe were finally sent by them to Koch, and in his reply to their claims, he held that their cultures were impure, and contained four distinct forms of bacteria. Two of these which are unimportant, are respectively known as the "figure bacillus of Finkler and Pryor," and the "green Finkler and Pryor." The third one, known as the "comma-bacillus of Finkler and Pryor," resembles very closely the Koch comma-bacillus in its morphological appearances, but is a little thicker and larger, and can be readily distinguished from it by the appearance of the colonies in different culture media.

Shortly preceding the communication from Finkler and Pryor, came the announcement almost simultaneously from Prof. Miller, of Berlin, and Lewis, of London, of the discovery of a comma-bacillus on the teeth, and in the mucus of the normal human mouth. It has been impossible to isolate this germ[1] from the fact that it will not grow in any of the ordinary culture media. In February, 1885, Prof. Miller, of Berlin, isolated a comma-bacillus from the mouths of two persons who were suffering from dental caries, but this, which was at first supposed to be the germ ordinarily found there, is probably another form and may be identical with the Finkler and Pryor comma.

The third comma-bacillus was described by Dr. Deneke, in January, 1885. This was found by him in stale cheese, and perhaps resembles more closely the Koch comma than either the Finkler and Pryor or the mouth comma. Still, Deneke concludes that it is quite distinct from it.

The greatest interest naturally centres in the Finkler and Pryor and the mouth commas, since, as these are both found in the alimentary canal under other conditions than with the existence of cholera, if the identity of either of them with the Koch comma-bacillus can be proven, Koch's conclusions will be completely invalidated. This has not been done, but, on the other hand, they have been proven to be very different from the latter.

As to the points of difference between the Finkler and Pryor and the Koch comma-bacilli, it must be admitted that in preparations mounted in Canada balsam, the similarity between the two germs is very great, but in preparations freshly stained and mounted in water, with the same magnifying power, the Finkler and Pryor comma appears somewhat larger and plumper. The differences shown in the growth and development of the colonies in different culture media are very great. Under the same con-

[1] Klein claims to have isolated the comma-bacillus of the mouth by using a slightly acid gelatine. Other observers have not been so successful, and his statement remains, as yet, unconfirmed.

Digitized by Google

ditions of life, *i. e.*, the same temperature and culture medium, the growth of the Finkler and Pryor comma is much more rapid than that of the Koch comma. In gelatine plate cultures[1] the single colonies of the Finkler and Pryor comma, especially during the first twenty-four hours of its growth, have a yellow-brown color, are always of a regular, round, sharp-bordered form, and present with the low and middle magnifying power, a fine granulated appearance. They rapidly liquefy the gelatine, so that after twenty-four or thirty-six hours the colonies have sunk deep into the layer of gelatine on the culture plate, and have surrounded themselves with a wide zone of the fluid medium. They produce in their growth a very foul and penetrating odor. After thirty-six or forty-eight hours, the colonies lose their circumscribed sharp bordered character and assume an irregular bushy form. So great is the tendency to liquefy the gelatine in wide areas around the individual colonies, that after the second day gelatine plate cultures, which contain but few colonies, have become entirely fluid.

Quite otherwise is it with the cholera comma-bacillus, the colonies of which, under completely the same conditions of existence, grow much more slowly and are colorless. Liquefaction of the gelatine in the neighborhood of the colonies proceeds only slowly, so that they sink deeply into the gelatine and form a deep narrow funnel-shaped depression. Each colony occupies the apex of a funnel and produces a distinct white point there. Even to the naked eye this appearance is very characteristic. The microscopical appearances of the colonies is especially characterized by an uneven and jagged border, and the entire colony appears as if made up of glancing pieces of finely broken glass. There is no development of any odor even after five or six days, or, at most, only a slightly aromatic odor.

Still more decided if possible are the differences in cultures in reagent tubes. These are well shown in these cuts, made from drawings[2] of cultures in the Carnegie Laboratory. The Finkler and Pryor, after two or three days, has rendered fluid the culture medium not only on the surface, but also throughout the entire length of the line of inoculation, and presents the form of a long slender pouch, or a deep narrow funnel. In cultures of the cholera bacillus prepared in a quite similar manner, the liquefaction of the gelatine is never present, at first, throughout the entire length of the line of inoculation, but appears only at the upper end, forming here a sharp bordered funnel or crater-shaped depression which apparently encloses an air bubble. The lower portion of the line of inoculation appears for some time as a fine white line. These points of difference in the appearance of colonies of the different germs in geletine tube and plate cultures are exceedingly characteristic and very constant, and almost all observers working independently have arrived at the same conclusions and agree that it is scarcely possible to confound these two comma-bacilli.

d. Line of inoculation. Growth of germs appearing at upper end.

On potatoes the cholera germ does not grow at all at a temperature below 32° C. At the temperature of the body it forms a dark brown layer. On the other hand the comma-bacillus of cholera nostras, or Finkler and Pryor, grows rapidly at 18° C., forming a thick yellowish-gray layer.

The comma-bacillus of the mouth, as isolated by Prof. Miller, of Berlin, resembles very closely the Finkler and Pryor comma-bacillus, both in its mor-

[1] A word of explanation may be added as to the method of making plate cultures of microörganisms. It is done in the following manner: A test-tube about one-third full of carefully sterilized nutrient gelatine is heated slightly until the gelatine becomes liquid. This is then inoculated by means of a slender platinum wire, either from some other culture of the germs required or from any substance or liquid containing germs that it is desired to isolate and study. After inoculation the tube is thoroughly shaken to distribute the germs evenly through the fluid. This forms what is known as the first dilution. From this a second tube is inoculated in exactly the same manner, and forms the second dilution. Sometimes even a third is made. The contents of the tube containing the second or third dilution are then poured out upon a sterilized glass plate that has been rendered cold by placing over ice-water. On this the gelatine quickly solidifies in a thin layer. The microörganisms which have been mingled with the gelatine, and have been thus separated and isolated, are fixed wherever they may fall, and from each individual a colony develops. Of course, these colonies, each of which develops from a single germ, form absolutely pure cultures of that germ. In this way the development of the colonies of different germs may be studied under the low power of the microscope, and by the peculiarities shown by the different colonies in their growth, the germs can be isolated with little difficulty.

[2] I wish to acknowledge my indebtedness to Dr. Frank Grauer, of the Carnegie Laboratory, who very kindly made the drawings of the cultures for me.

phological appearances and its manner of growth in different culture media. Although its identity with the Finkler and Pryor has not been satisfactorily proven, yet their similarity is so great, and it can be

distinguished so readily, from the Koch comma, by the characteristics shown in the growth and development of the colonies in different culture media, that it seems unnecessary to consider it more fully here.

As far as the writer's own experience is concerned in the cultivation of microörganisms, he has never found any kind of bacteria comma-shaped or otherwise, which could for a moment be mistaken in cultures for the Koch comma-bacillus, where the whole life history of the germ was taken into consideration.

Nicati and Rietsch, of Marseilles, succeeded in producing death in dogs with choleraic symptoms and lesions, after first ligating the common bile-duct and then injecting into the duodenum a small quantity of material from a pure culture of the Koch comma-bacillus. The same results were obtained in the case of guinea-pigs without previous ligation of the bile-ducts. When in place of the Koch comma-bacillus, the Finkler and Pryor was used by other observers, the results, in a large proportion of cases, were entirely negative. After death almost pure cultures of the Koch comma-bacillus were found in the contents of the intestinal canal. These experiments have been repeated and confirmed by Koch and others in Germany, but, on the other hand, certain English observers have absolutely denied the correctness of the results obtained, and claim that the effects of both the Koch and the Finkler and Pryor comma-bacilli are absolutely nil.

At the second meeting of the Cholera Conference in Berlin in May, Koch reports the methods and results of his experiments as follows. The guinea-pigs first receive 5 ccm. of a 5 per cent. solution of soda, and 20 minutes later 10 ccm. of beef bouillon, containing the comma-bacilli, is injected into the stomach. Immediately after this, tincture of opium (1 ccm. to each 200 gramme weight of the animal) is injected into the peritoneal cavity. The animals are narcotized by this for from half an hour to an hour, then they recover again completely. The following day they seem to be sick, and die after from one to three days. The autopsy shows swelling of the small intestines, which, together with the stomach and cæcum, are filled with an alkaline, colorless, flaky fluid containing almost pure cultures of the comma-bacilli. Eighty-five experiments were made in this manner with the same result in each case.

Koch further added that from the 150 physicians who took the cholera courses during the autumn and winter, one had a mild attack of cholera and in his stools the comma-bacilli were found.

These experiments on guinea-pigs cannot by any means be received as constituting absolute proof of the causal relation of the comma-bacillus to cholera, even when taken in connection with all the other known facts, but may be regarded as affording additional confirmatory evidence.

Emmerich, of Munich, in Dec. 1884, described a short straight bacillus, which he believed was the cause of cholera. This bacillus he found in the blood and tissues of a number of persons either suffering from or dead of cholera, and he claimed to have produced death in animals with choleraic symptoms after administering fluids to them, which contained this germ. But the methods of his work were not reliable and his conclusions have not been accepted.

The next publication that especially deserves attention is the report of the English Cholera Commission, which was sent to India to investigate the etiology of cholera. From this report, a summary of which is given below, it will be seen that there is not a single important point in Koch's conclusions, with which they do not take issue, with the exception of the constant occurrence of this microörganism in cholera cases. However, they do not believe its presence is confined at all to this disease, but practically assert that it is a putrefactive germ, is not to be distinguished from other putrefactive microörganisms, either by its morphological appearances, its life, history, or the peculiar characteristics of its growth in different culture media, and, in a previous report, state that it occurs under various other conditions, such as simple diarrhœa, phthisical diarrhœa, etc.

It is especially necessary to note here that in the work of the English Cholera Commission almost entire reliance was placed on the microscopical examination, and that the culture tests were used but little, if at all, to determine the presence of the Koch comma-bacilli. Now it has been repeatedly shown that the microscopical examination is entirely unreliable, and that this germ cannot, with certainty, be differentiated from the Finkler and Pryor comma-bacillus and other forms of bacteria without the aid of the culture tests, so that their work is practically excluded at the very beginning. The conclusions of the Commission are as follows:

1. Koch's statements as to the constant occurrence of comma-bacilli in the rice water stools of cholera patients is correct: the comma-bacilli vary greatly in numbers in different stools and in different cases, in some being exceedingly scarce, in others numerous.

2. These comma-bacilli vary greatly in length, some being twice or three times as long as others, some well curved, as much as to form half a circle, others showing only just a slight bend. The name comma-bacillus is inappropriate; the organism is more correctly termed a vibrio.

3. The comma-bacilli occur in the mucous flakes of the rice-water stools as well as in those taken from the ileum of a person dead of cholera. The sooner after death the examination is made the fewer comma-bacilli are found in the mucous flakes. Even in typical fatal cases the mucous flakes taken from the ileum, and examined soon after death (from between fourteen minutes to an hour or an hour and a half), contain the comma-bacilli only very sparingly indeed, and not to the exclusion of other bacteria. Our investigations do not bear out Koch's statement as to the lower part of the ileum being, in acute typical cases of cholera, almost "a pure cultivation of comma-bacilli." In not one of the many post-mortem examinations of typical acute cases have we found such a state.

4. The mucous membrane of the ileum in typical rapidly fatal cases, if examined soon after death, does not contain in any part any trace of a comma-bacillus or any other bacteria, not even in the superficial loosened epithelium. If the post-mortem examination be sufficiently delayed, comma-bacilli and other bacteria may be found penetrating into the spaces of the mucous membrane. Koch's theory as to the comma-bacilli present in the mucous membrane secreting a chemical poison inducing the disease cannot, therefore, be correct.

5. Neither the blood nor any other tissue contains comma-bacilli or any other microörganisms of known character.

6. The behavior of the comma-bacilli in artificial media is not such as to justify their being considered as specific. They grow well in alkaline and neutral media, are not killed by acids, and their mode of growth in gelatine mixtures is not more peculiar than that of other putrefactive bacteria; they show marked differences when growing in different media, but not more so than the ordinary putrefactive bacteria when compared in their growth with one another. The *comma-bacillus of the mouth* shows the *same peculiar character* of growth in gelatine as Koch's comma-bacilli.

7. Koch overlooked the fact that "comma-bacilli" occur in other intestinal diseases in the mouths of healthy persons, and, as shown recently, even in some common articles of food (by Dr. Deneke, in stale cheese).

8. The experiments performed by Koch and others on animals do not, in the least, prove that the comma-bacilli are capable of producing cholera or any other disease. The results obtained by them are much more easily explained in an opposite manner.

9. There is direct evidence to show that water contaminated with choleraic evacuations, and containing of course the comma-bacilli when used for domestic purposes, including drinking, by a large number of persons, did not, in the case of the tanks near the Jelepara Lane, produce cholera.

10. The mucous flakes taken from the small intestine of a typical rapidly fatal case of cholera contain numerous mucous corpuscles filled with peculiar minute straight bacilli; in this state they are found when the examination is made very soon after death; soon, however, the mucous corpuscles swell up and disintegrate, and then their bacilli become free. The small bacilli are never mixed in the mucous flakes. They are one-third or one-fourth the length of the comma-bacilli and about half of their thickness. They are non-mobile; they grow well in agar-agar jelly, but show in their modes of growth no peculiarity by which they could be considered as specific. When grown on the free surface of the nourishing material they form spores.

11. These small bacilli are not present in the blood in the mucous membrane of the intestine, or in any other tissue.

12. Experiments made with these small bacilli on animals produced no result.

13. Since my return to London I have ascertained that the comma-bacilli of cholera show two distinct modes of division, one the known one of transverse division, and a second one of division in length. When growing in agar-agar jelly at the ordinary temperature of the room, after some days the bacilli swell up owing to the appearance in their protoplasm of one or more vacuoles; as these vacuoles increase, the comma-bacilli become gradually changed, first into the plano-convex, then into oblong biconvex, and ultimately into circular corpuscles. The longer the original comma-bacillus the larger the final circle. These circular organisms are mobile just as are the comma-bacilli; and by disintegration of the protoplasm at two opposite points two perfect more or less semicircular comma-bacilli are formed. Growing the comma-bacilli in agar-agar jelly kept at higher temperatures (30 to 40° C.), the comma-bacilli multiply by transverse division only; but transferring these to agar-agar jelly, and keeping at the ordinary temperature of the room, they again gradually change into circular organisms, which by division in the diameter of the circle form two new comma-bacilli.

From this report it will be seen, as was before stated, that there is not a single important point in Koch's deductions with which the English investigations do not take issue, with the exception of the constant presence of the comma-bacilli, in all cases of cholera, both intra vitem and post mortem.

Let us consider briefly each of the important points of these conclusions:

3. In the third article Klein states that the sooner after death the examination is made the fewer comma-bacilli are found in the mucous flakes present in the contents of the ileum, and in no case was anything approaching a pure culture found. The examination upon which this statement is made were simply microscopical in character, and Cheyne has shown (as all workers in bacteria should have known), that this method of examination is entirely unreliable, since in typical rapid cases where microscopical examination showed but few comma-bacilli, culture experiments proved that from 70 to 90 per cent. were the comma-bacilli.

4. In the fourth article Klein states that neither comma bacilli nor any other microörganisms are present in the mucous membrane of any part of the intestines soon after death, and that Koch's theory as to the comma-bacilli present in the mucous membrane secreting a chemical poison inducing the disease, cannot, therefore, be correct. Positive evidence is always more valuable than negative, and, as is well known, many microörganisms in tissues are difficult to stain. Koch is the great master of this art, and his statements on this point must be accepted.

6. In the sixth article Klein states, in substance, that the growth of these germs in culture media is not different from putrefactive germs in general, and that they are putrefactive microörganisms. All other competent observers, without exception, agree with Koch on this point that the growth of the comma-bacilli in both tube and plate cultures is very characteristic and very constant. Klein further states that the comma-bacilli of the mouth show the same characteristics in cultures as the Koch comma. This he afterwards admitted was not the case.

7. In the seventh article Klein states that Koch overlooked the fact that comma-bacilli occur in other intestinal diseases, in the mouth of healthy persons, and in certain articles of food. Here, as everywhere through the report, the comma-shaped form of the bacillus is assumed to be the distinguishing characteristic of the cholera germ. This is not by any means the case. That Koch did not know at that time of the existence of the comma-shaped bacilli to which Klein refers is true, but he did know of the existence of other comma-shaped bacilli, and refers incidentally to them in his report.

8. As to the experiments on animals with the Koch comma-bacillus, it is not claimed that these experiments, in producing cholera in animals, absolutely prove that the cholera-bacilli are the cause of cholera, but that they constitute strong confirmatory evidence in that direction.

9. The same may be said of the ninth article as was said of the fourth, namely, that he depended entirely upon morphological appearances, and did not resort to culture tests.

10. It is not necessary to refer to the small bacilli described by him, as no claim is put forward for them, and as they were regarded as putrefaction germs.

13. As to the transverse division described by Dr. Klein, as sometimes occurring in the cholera-bacilli, it is only to be said, that it has not been observed by any other investigator, and, under any conditions, it has no bearing upon the relation of the microörganism to the disease.

Dr. Van Ermengen, in the report of his researches upon the microbe of cholera, undertaken on behalf of the Belgian government, entirely confirms Koch's conclusions in every particular.

Mr. Watson Cheyne, in his admirable report on the cholera bacillus to the Scientific Grants Committee, differs from the conclusions of the English Commission on every disputed point, and completely confirms the conclusions of the German Commission.

In the *British Medical Journal*, of May 9th and 16th, Dr. Klein details the results of some further investigations on the cholera bacillus. He states (*British Medical Journal*, May 16th) that, in the cæcum of normal guinea-pigs, "the typical comma-bacilli of Koch may be found;" and gives (*British Medical Journal*, May 9th) the results and some experiments, to establish the opinion which he had previously advanced, namely, that the Koch comma-bacilli, merely found in the intestines of cholera patients, under the conditions favorable for their multiplication, bear no essential causal relation to the disease; that is to say, they are the result, and not the cause, of the disease. He says, "in a monkey, which had received a dose of castor oil the previous evening, the abdomen was opened under spray, the lower ileum was drawn out, one ligature tied just above the ileo-cæcal valve; another about 2–4 inches higher up; the larger vessels of the mesenteric border were avoided as much as possible; into this loop a hypodermic syringe, full of a saturated solution of

Digitized by Google

magnesium sulphate, was injected; the ileum was replaced; the wound was stitched up; a bandage was applied, and was covered with collodion. Careful antiseptic precautions were observed throughout. In this manner six monkeys were operated on. One of the animals was dying the same evening; one was dying after three days were over; the others were killed after forty-eight hours."

"No comma-bacilli were found in the contents of the ileum withdrawn before the ligation of the loop of intestines. In three of the animals killed after forty-eight hours the tied loop contained a brownish fluid with many mucous flakes. In the contents were found numerous comma-bacilli. In one case they were more numerous than in some typical acute cases of cholera. It is evident from this that the pathological state of the intestines produced the conditions favorable to the multiplication of the comma-bacilli; and that they are, therefore, the *result*, and not the *cause*, of the disease. I am unable to distinguish them from the cholera comma bacilli, and they appear to be identical with the latter."

As Watson Cheyne denies the presence of the Koch comma-bacilli in the cæcum of normal guinea-pigs, and the results of Klein's experiments seem too improbable to be accepted until further confirmed, especially as so few details are given, it seems probable that Dr. Klein has fallen into the same error as before, namely, of depending upon morphological appearances, instead of culture tests.

Finally, as to the inoculation experiments with the cholera bacilli of Dr. Ferrán, there seems to be not the slightest ground for giving them any credence. Granted, in the first place, that the Koch bacillus is the cause of cholera, even then there is nothing to be hoped for from protection by inoculation, for reasons too evident to call for remark. It seems altogether probable that the peculiar phases which Ferrán describes as occurring in the life of the comma-bacillus are due to impurities in his cultures, and that it is to these impurities that the effects of his inoculations are to be ascribed.

We have now considered most of the important points at stake in the controversy, and can draw our conclusions as to the present status of the Koch comma-bacilli. The recent discussion before the Medical and Surgical Society in London elicited no new facts, and it is not necessary to refer to it more fully. These conclusions, then, may be drawn:

1. That Koch's claims as to the discovery of a germ peculiar to cholera, which possesses certain morphological and biological characteristics, that differentiate it sharply from all other germs, have stood the test of investigation by many observers, and remain yet to be disproved.

2. It is acknowledged by all investigators, without exception, that the Koch comma-bacillus is always found in Asiatic cholera in greater or less numbers, and that it is absolutely diagnostic of cholera, whether it bears any etiological relation to the disease or not.

3. That, although it cannot be considered as absolutely proven that the Koch comma-bacillus is the cause of cholera; yet its constant presence in this disease, and its absence under all other conditions, its relation to the course and intensity of the disease processes, and its peculiar life history, constitute very strong presumptive evidence in this direction.

4. Whatever may be the ultimate conclusion of medical men on this question, that still the greatest honor is due to Dr. Koch for having placed at our disposal a method for the diagnosis of Asiatic cholera.

21 EAST TWENTY-FIRST ST., NEW YORK,

A NEW BANDAGE FOR FIXATION OF THE HUMERUS AND SHOULDER-GIRDLE.

BY CHARLES W. DULLES, M.D.,

FELLOW OF THE COLLEGE OF PHYSICIANS AND OF THE ACADEMY OF SURGERY OF PHILADELPHIA; SURGEON TO THE OUTPATIENT DEPARTMENTS OF THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA, AND OF THE PRESBYTERIAN HOSPITAL, IN PHILADELPHIA.

IN the treatment of injuries about the shoulder-joint, such as luxation, contusion, fracture of the clavicle, or of the acromial end of the scapula, etc., I have often felt the need of some form of bandage, which, while as efficient as the Velpeau or Desault bandage, should be less cumbrous; and I have been led to try various modifications of these until I hit upon a way of bandaging which has been so satisfactory to me and to my patients that I wish to bring it to the notice of my professional brethren, and to obtain their judgment upon its merits.

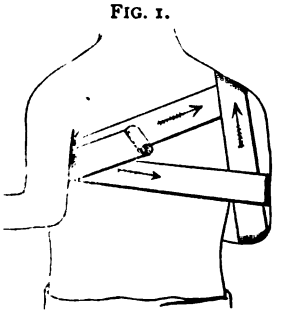
This form of bandage requires, for an adult, a roller about three and a half inches wide, and about ten or twelve yards long. It is applied as follows:

The arm of the injured side should be placed against the chest-wall, almost in the perpendicular line, but with the elbow a little in advance, and the forearm flexed at a right angle and laid across the lower part of the chest.

A large piece of lint, or a soft towel, or a piece of old muslin, should now be interposed between the arm and the body, going well up into the axilla, so as to prevent the excoriation which usually results from the apposition of two skin surfaces.

Then the surgeon, standing behind the patient, and a little toward the injured side, should apply the initial end of the roller to the axilla of the sound side, and carry the bandage diagonally across the

FIG. 1.



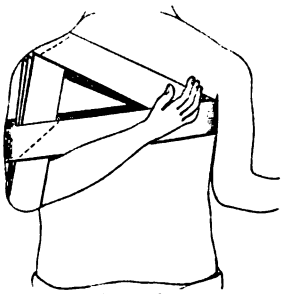
Back view.

back to the top of the shoulder of the injured side; then straight down the front of the arm to the point of the elbow; then under this to the back of the arm; then up behind the arm to the shoulder, where the

Digitized by Google

preceding turn crossed it At this point a firm pull should be made on the bandage, to draw the humerus well up against the glenoid cavity. In cases of fracture of the clavicle or scapula, this piece can easily be regulated so as, with the aid of a little manipulation, to place and keep the ends of the bone in position. Then the bandage is to be carried diagonally across the front of the chest to the axilla of the sound side; then through this axilla to the back; then horizontally across the back to the lower third of the arm of the injured side, and round this to the front of the arm; then across the front of the

FIG. 2.

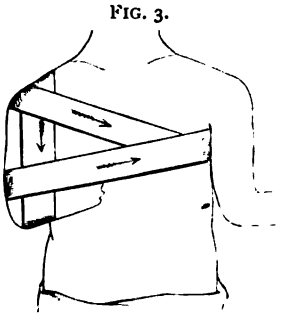


Front view.

chest to the axilla of the sound side, leaving the forearm out; then through this axilla to the back near the point of starting. The appearance of the bandage when one complete circuit has been made is shown (back and front views) in Figures 1 and 2. The bandage is completed by repetition of these turns till the roller is used up, advancing with each turn a little way up on the shoulder, and a little way up on the arm. If one roller does not suffice to give the support desired, of course a second must be added (Fig. 3).

After the bandage is in place a few large pins should be inserted at each crossing, and the hand and

FIG. 3.



Front view.

forearm should be supported by a sling. In addition to the pins, the bandage may be stitched so as to make a firm case; or a few strips of adhesive plaster may be applied along and across it in different places, which will give the greatest possible security. It is a good plan to attach a strip of adhesive plaster, an inch and a half wide, from just below the shoulder, over the outer side of the arm and round the point of the elbow, to about the middle of the forearm. This will prevent the bandage from slipping off the elbow.

In certain cases it is advisable to include the forearm in the bandage, so as to bind it firmly to the chest-wall. But one of the special advantages of this method, in my opinion, depends upon the fact that it can usually be employed without including the forearm.

This form of bandage accomplishes the following results: It fixes the scapula and the outer end of the clavicle, holds the head of the humerus well up against the glenoid cavity, and fixes the whole bone against its natural splint, the chest wall. Among its advantages the most important, in my opinion depends upon the exactness with which, by drawing up the humerus in the line of its axis, the bone and the shoulder-girdle can be held in a position in which there is the least muscular interference with the proper position of the fragments in a fracture of the scapula or clavicle, or of the different bones in a luxation at the shoulder-joint. I find that, with a little manipulation with my free hand, and careful regulation of the upward pull upon the humerus and the downward pressure upon the scapula or clavicle, by means of the bandage as it goes along, I can get all that I can ask for in the way of correct anatomical relation of parts. The position of the humerus, which I have indicated, is also, I believe, a better one than that which is maintained by the bandage most frequently employed—I mean the Velpeau bandage.

The comparative lightness of this dressing is also an advantage, as well as the fact that it leaves the upper and lower ends of the arm uncovered, so that they may be examined at any time, or have applications made to them. The freedom of the forearm I have already alluded to as an advantage whenever it is admissible.

There is no danger of the bandage slipping, if it be snugly and firmly applied, and if it be wide enough. It is easy to make it fit nicely at the elbow, so as to hold this in a sort of cup made by the slight elasticity of the material.

It is also easy, by varying the position of the turns, to make the bandage cover any particular point in the scapula, or in the outer end of the clavicle, or in the humerus. In fractures of the clavicle, or scapula, a suitable compress may be placed over the seat of fracture; while, in any fracture of the humerus, to which such a dressing is suitable, the arm may be splinted against the chest-wall by carrying the horizontal turns high up.

I will not attempt to speak of the conditions to which this form of bandage is applicable, but I think they are all those in which fixation of the arm and shoulder-girdle is the important object.

I am aware that it is somewhat dangerous to call anything new in these days, but I have so designated the bandage I have just described, because I have not met with any description which corresponds to it. If I am mistaken, I shall be happy to be corrected.

DISINFECTANTS.

PRELIMINARY REPORTS OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

XV.

CONSIDERATIONS CONCERNING THE PRACTICAL USE OF MERCURIC CHLORIDE AS A DISINFECTANT.

BY VICTOR C. VAUGHAN, PH.D., M.D.,
PROFESSOR OF PHYSIOLOGICAL CHEMISTRY IN THE UNIVERSITY OF MICHIGAN.

SINCE mercuric chloride has been put forward as one of the most reliable disinfectants, its practical use has been largely discussed, and some supposed dangers in its general employment have been brought forward. It was for the purpose of ascertaining how much truth there may be in these statements that the following experiments were undertaken.

Is there danger of the passage of this highly poisonous salt from cesspools and privy-vaults, in which its use has been recommended, through the soil into wells? Sanitarians have had so much to say about well-water being poisoned by the filtration of organic matter through the soil from privy-vaults and cesspools, that it is not surprising that the above question should be asked. In order to answer it, the following experiments were made:

Experiment 1.—A large glass funnel carrying a filter-paper was filled with gravel, taken from a distance of about four feet beneath the surface. The weight of the gravel was eleven and three-fourths pounds, and, when placed in the funnel, it formed an inverted cone with a base of ten inches diameter and an altitude of eight inches. On this was poured one pint of standard solution No. 2 (corrosive sublimate and permanganate of potash, two drachms of each to the gallon of water), recommended for the disinfection of excreta. After a few minutes a pint of distilled water was also filtered through the soil. This was done in order to wash through any mercury that might be held mechanically in the gravel The filtrate was collected, concentrated to one fluidounce, and tested for mercury. The result was negative. The soil retained all of the poison.

Experiment 2.—This was similar to the above, but black loam was used instead of the gravel. The weight of the soil used was seven pounds. The result was the same as with the gravel.

Experiment 3.—In this instance, clay was used. The weight of the clay was nine and one-fourth pounds. As the soil in this case was very dry, it was thoroughly moistened with water before the solution of mercuric chloride was poured on.

These experiments show that the quantities of the different soils, as given above, will remove from solution and retain all the mercury contained in one pint of standard solution No. 2,—fifteen grains of mercuric chloride. That a much smaller amount of soil would accomplish the same result, was shown by the following:

Experiment 4.—One and one-half pounds of gravel were placed on the filter, and one pint of standard solution No. 2—one ounce at a time—was filtered through the gravel. The filtrate contained no mercury.

From these experiments it will be seen that the fear that mercuric chloride may filter through the soil, when used as a disinfectant in privy-vaults and cesspools, into wells and thus poison the water, is groundless. Of course, where there is open connection between the cesspool and wells by the formation of small subterranean rivulets, there would be danger. The fixation of mercury in the soil is doubtless largely, if not wholly, due to the presence of certain inorganic salts, such as carbonates and phosphates, which form insoluble compounds of mercury.

At the recent Cholera Conference at Rome, Dr. Koch gave, as one of his reasons for not recommending mercuric chloride as a disinfectant, the belief that its disinfecting action was interfered with by the fact that it entered into combination with albuminous material, and thus failed to come into contact with germs enclosed in albuminous masses.[1] That a combination between the mercury and albumen does occur may be shown by the following very simple test:

Experiment 5.—Suspend some recently precipitated mercuric oxide in distilled water, add some egg-albumen, agitate thoroughly, and filter. The filtrate is clear and colorless. Boil this filtrate with potassium chlorate and hydrochloric acid until all the organic matter is destroyed. Then test for mercury with hydrogen sulphide or stannous chloride. The mercury will be found to be present, and all that which was used as mercuric oxide can be recovered.

Albumen dissolves the oxide, forming, probably, mercuric albuminate; but there is no reason for believing that the mercuric albuminate does not diffuse through organic matter. As shown in the experiments, it is freely soluble and readily passes through the filter-paper. It is altogether probable that it is this mercuric albuminate which forms such a powerful germicide. In this compound we have the mercury in the shape in which it would most likely be taken up by those lower forms of life which feed upon albuminous material.

Medical men have, for a long time, regarded "yellow wash" as the most successful application that could be made to syphilitic sores. Is it not likely that its great value is due to the formation of mercuric albuminate, which has a local action on the virus, and penetrates the tissue as well? A substance which is not absorbed by living organisms is not poisonous to them, and if by the formation of this mercuric albuminate the most readily absorbable form of mercury is secured, its poisonous properties are intensified.

Further considerations concerning the use of mercuric chloride will be presented as soon as some additional experiments are made. The writer is indebted to two of his students, Messrs. Wagner and Bobb, for aid in the experimental work.

Note.—By Dr. G. M. Sternberg, Chairman of Committee.

I have recently made some experiments to deter-

[1] THE MEDICAL NEWS, June 20, 1885, p. 707.

Digitized by Google

mine the antiseptic power of mercuric oxide. In the proportion of 1 : 1000 it has prevented any development of microörganisms in veal broth, inoculated with two or three drops of "broken-down" beef-tea. In the proportion of 1 : 2000 and 1 : 4000, it restrained development for a time, but at the end of forty-eight hours the broth became clouded near the surface, and at the end of seventy-two hours, had broken down completely. (The same culture-fluid broke down in 24 hours when not treated with an antiseptic.) This very decided antiseptic power shows that mercuric oxide is far from being "inert" from a biological point of view.

A CASE OF INFLAMMATION OF POSTERIOR BRONCHIAL LYMPHATIC GLANDS LEADING TO FATAL HEMORRHAGE.

BY D. W. BARRY, M.D.,
OF VIENNA, AUSTRIA.

PATIENT, aged 71 years, female; well developed and robust-looking, entered the Allgemines Krankenhaus in May of this year. Complained of "spitting blood." She was examined, but no sign of tuberculosis was found; but, on the contrary, a high grade of emphysema; patient had not lost flesh, had no night-sweats, and gave no history that would tend to show phthisis; nevertheless the case was set down as probably a case of phthisis, owing to the great frequency of this disease in Vienna.

Following a profuse hemorrhage she died, and the autopsy revealed the following:

Brain slightly adherent to dura mater, and atrophic —as would be expected from age of patient—otherwise nothing pathological was found.

Larynx and trachea filled with a blood clot which reached from the vocal chords into the bronchial tubes.

Lungs highly emphysematous; no tubercles were found.

Heart small, fatty, with slight senile thickening about the valves, and slight atheroma at the base of the aorta.

The stomach was then examined in the hope of there finding some cause for the hemorrhage, and was found to contain about four ounces of semi-coagulated dark blood. On the gastric mucous membrane no ulcer or other pathological condition was found.

The lungs, heart, œsophagus, etc., were then carefully dissected out, and, on opening the œsophagus, a small orifice was found on its anterior surface through which a probe could only be passed to the depth of about one-fourth inch. The trachea was then opened, and on its posterior wall, about one inch and a half below the orifice, in the œsophagus, an ulcer was found through which a probe was made to pass into the œsophagus at the orifice in its anterior surface.

As this could not be the cause of the profuse hemorrhage, the trachea was opened completely, the cut extending into the larger bronchial tubes; and in one of these, on the left side, a large, irregular orifice was found which led into one of the posterior bronchial lymph glands; this, on being opened, was found to be completely broken down, and contained blood coagula, necrotic tissue, and, covering the inside surface, was a layer of quite hard fibrine.

On further examination several fistulæ were found, one leading into the trachea, another into the bronchus, and still a third, and more recent, which led into the vena cava superior; this last fistula explained everything, as it was, without doubt, the cause of the last and fatal hemorrhage.

In closing I may say that in this case the autopsy explained fully all the symptoms; as, quite likely, during the slow inflammation of the lymph gland no particular distress was felt, and it was not until a communication was formed between the gland and bronchus that the patient commenced to expectorate blood, and then she sought medical aid. The bleeding at first was small, and probably came from the gland or bronchial tubes; it increased in quantity as the inflammation increased, and the last profuse hemorrhage followed the ulceration into the vena cava.

MEDICAL PROGRESS.

TREATMENT OF INFANTILE CORYZA.—DR. FLATOW, in the *Deutsche Med. Zeitung*, recommends the following treatment for infantile coryza:

℞.—Quiniæ hydrochlor. . . . 1 part.
Glycerinæ . . . . . 15 parts.—M.

S.—Apply a few drops with a brush to the nasal mucous membrane three or four times a day.—*L'Abeille Médicale*, August 3, 1885.

NEPHRECTOMY.—On the 14th of July, Mr. Clement Lucas removed, in Guy's Hospital, by lumbar incision, a large cystic floating kidney, filled with calculi of such a size that they could be felt through the abdominal wall and be made to grate one against another. The organ was removed without injury to the peritoneum, and the patient has progressed most favorably, her temperature since the operation never having risen above normal. On the 16th inst., Dr. George Elder, of Nottingham, performed the same operation on a woman aged fifty-six, for calculous pyelitis, the temperature being normal on the third day after removal of the kidney.—*The Lancet*, July 25, 1885.

TREATMENT OF WHOOPING-COUGH.—H. ROGER recommends the following mixture in the treatment of whooping-cough:

℞.—Tr. belladonnæ . . . f℥v.
Tr. valerianæ,
Tr. digitalis . . . āā f℥iss.—M.

Five drops of the mixture for children under two years. Each day the dose is augmented five drops until thirty drops are given in twenty-four hours. In patients from two to five years old ten drops should at first be prescribed, and every two days the dose increased until it reaches sixty drops. In case the tincture of valerian is badly tolerated it should be replaced by some other tincture—musk, for example. When nervous and spasmodic symptoms are prominent, the author has recourse to chloroform; and in children from two to five years of age administers from six to thirty drops of the drug in any appropriate menstruum.—*L'Union Médicale*, August 6, 1885.

PAPAYOTIN IN DIPHTHERIA.—DREIER, in *Vratsch*, 1885, No. 15, reports the results of the use of papayotin in the treatment of diphtheria, at the Wladimir Hospital, Moscow.

A five per cent. aqueous solution was prepared daily, and applied profusely to the diseased regions of the throat every fifteen minutes. At night the drug was applied at intervals of two hours. In addition the fauces were washed four times every twenty-four hours with a 1 to 1000 solution of corrosive sublimate. After tracheotomy, a few drops of the solution of papayotin were dropped every fifteen minutes into the canula. Stimulants were given early in bronchitis; a one per cent. solution of bicarbonate of soda was inhaled, and tracheotomy was performed early in the course of the disease.

Only cases in which the diagnosis was early confirmed were selected. Out of twenty-four cases, in six the disease remained local. In twenty cases the constitutional symptoms were manifested. In nineteen there was albuminuria; in one endocarditis; in one diphtheritic myocarditis; in two paralysis of the fauces; in one abscess of the neck; and in one acute nephritis. Of these, fifteen died. In three cases the air-passages were involved, and death occurred in every instance. The papayotin was in some cases applied for thirty hours; in others for periods varying between two, three, and five days, without having any influence upon the temperature or course of the disease. Post-mortem examination also showed the regions covered with the diphtheritic membrane to which the solution of papayotin had been constantly applied. The papayotin used was, however, variable in its action, and sometimes albumen, meat, and connective tissues were completely digested in five hours, while at other times they were only swelled and macerated.—*Centralbl. für klin. Med.*, July 25, 1885.

TREATMENT OF CATARRHAL PHTHISIS, HÆMOPTYSIS, AND CHRONIC BRONCHITIS BY TERPINE.—M. GERMAIN SÉE considers terpine to possess the power of modifying the mucous membrane of the respiratory tract, and to be also a powerful agent in checking its secretions. He says:

1. It diminishes and causes the disappearance of the purulent expectoration in the catarrhal forms of phthisis, since the purulent secretion proceeds from bronchi irritated by tubercle or from the walls of pulmonary cavities; when the patient is in the beginning of the purulent stage, or, indeed, in the stage when cavities are beginning to form, terpine is indicated in all cases where the formation of pus is sufficient to fatigue the patient, destroy his strength, and cause wasting.

2. It is employed with success in hæmoptysis of beginning tuberculosis—that is to say, when the disease has not yet advanced to the development of large cavities with aneurism of the pulmonary artery.

3. In the treatment of pulmonary catarrh, chronic bronchitis independent of asthma, and only causing dyspnœa by obstructing the bronchi, terpine constitutes the best means of decreasing the secretion.

4. Its action, prompt, certain, and free from physiological inconvenience should make it preferable to preparations of tar and turpentine. It presents, moreover, on account of its perfect harmlessness, and easy digestibility, advantages over creasote.

5. The best mode of administering the drug is either by pill or in alcoholic solution. The best dose is fifteen grains.

6. In the treatment of nervous asthma, emphysematous or catarrhal, which must be distinguished from primitive catarrh, iodine and pyridine possess undoubted superiority.—*L'Abeille Médicale*, August 3, 1885.

GUNSHOT WOUND OF THE TRACHEA, FOLLOWED BY DEATH FROM EMPHYSEMA.—RYDYGIER, in *Przeglad lekarski*, 1885, No, 16, reports a case of gunshot wound of the neck, resulting in death from emphysema, notwithstanding the fact that tracheotomy was performed. The patient, a boy seventeen years of age, received the shot at a distance of about ten paces. After receiving the injury, the patient, unassisted, walked home, a distance of more than a mile.

No serious symptoms were manifested, the wound in the neck was scarcely the size of a pin's head and appeared dry, and the only application ordered by the attending surgeon was cold applications around the neck. On the following day there was slight emphysema of the skin around the wound, which extended in a few hours over the face and entire neck. At this time tracheotomy was performed; only temporary ease in respiration was experienced, however, and the emphysema continued to spread further until two days subsequently, when the patient died from suffocation.

Post-mortem examination showed that the bullet had perforated the cricothyroid ligament, the posterior wall of the larynx, the anterior and posterior wall of the pharynx, and had entered the sixth or seventh cervical vertebra. Here it turned at almost right angles, and appeared at the second thoracic vertebra and lay firmly embedded in the bone.

In both pleural cavities there were present about six ounces of bloody serum, while between the posterior wall of the larynx and the anterior wall of the pharynx was found pus, mingled with chyle. The cause of the continually increasing emphysema of the skin, in spite of tracheotomy, is difficult to determine, inasmuch as the perforation of the trachea was above the inserted tube. The termination of the case does not show tracheotomy, and, especially, its early performance, to be contraindicated in small wounds of the neck. The right-angled deviation of the ball is remarkable.—*Centralbl. für Chirurgie*, August 1, 1885.

CASE OF DOUBLE-SIDED TOTAL AMAUROSIS IN THE COURSE OF A SLIGHT ANÆMIA.—PROFESSORS M. LITTEN and J. HIRSCHBERG report the following singular case of complete double amaurosis occurring in the course of a slight attack of anæmia. The patient, a girl fifteen years of age, complained of having for some time previous noticed impairment of vision, and stated that for two days she had been entirely blind. The girl for her age was rather stoutly built, but seemed to be insufficiently nourished. The skin and mucous membranes were pale. The subcutaneous fat was scanty, but the muscles strong; menstruation began two years ago and occurred regularly. No history of illness, but for four weeks pain in the region of the stomach had

Digitized by Google

been present. Examination showed no abnormal condition of any of the thoracic or abdominal organs. The pulse was 120, weak, regular, and easily compressible. Over the jugular veins on each side a whirr could be heard and felt. The pupils on each side were alike exceptionally large and staring. The expression of the patient was strange and almost lifeless. Brain clear. Amaurosis absolute. Examination showed choked disk on each side. The optic nerve appeared slightly red and dull, the margins obscure, the veins dilated and choked.

Nothing abnormal was discovered in the urine. Microscopic examination showed a condition of the blood characteristic of anæmia. The white corpuscles were increased slightly in their proportion. In the absence of all other causes, diagnosis was made of amaurosis due to anæmia. In order to observe the progress of the case the child was sent to a hospital. Here she was treated with syr. ferri iodidi, and in addition was well fed and kept in bed. No further pain in her stomach was observed, and her appetite became voracious, and an improved condition of the blood was noted. At the same time the size of the pupils diminished and their staring appearance was less marked.

Three days after the patient's entrance into the hospital she recognized light for the first time, yet only sufficiently to distinguish between the greatest contrasts of darkness and light. Within the next eight days her ability to see improved so rapidly that she could determine whether a curtain was up or down, and also could distinguish large objects at the distance of half a yard with great difficulty.

From this time on there was continuous improvement of vision, but central scotoma persisted, diminishing, however, as time advanced. At the same time the swelling of the optic nerve diminished, and on July 11th a prominence was scarcely visible The veins, however, were distended and full, and exhibited marked pulsation. Ophthalmoscopic examination on July 15th showed the posterior eye-ground to be entirely normal. The general condition of the patient was also much improved and the blood on examination was found to be normal.

The sudden advent of amaurosis and the rapid and complete restoration of vision under appropriate diet and tonic treatment are in this case remarkable features.

From a therapeutic standpoint it is also worthy of remark that the use of the iodide of potassium which is advantageously prescribed in many cases of engorged papilla of central origin would probably have been harmful, while desired effect was obtained by tonic regimen together with the administration of iron.—*Berliner klinische Wochenschr.*, July 27, 1885.

TREATMENT OF NEPHRITIS WITH SUDORIFIC AGENTS.—DR. HESS (*Vratsch., St. Petersburg Med. Wochenschr.*) has used as a means of causing perspiration damp wrapping in fifteen cases, hot baths, with subsequent wrapping in woollen covers twenty-four times, and hot-air baths twenty-one times, and has made observations in six cases of nephritis so treated. His results are as follows:

1. The least rise of temperature is obtained by wrapping, and the greatest by use of the hot baths.

2. While the temperature twenty minutes after the wrapping again falls, it remains after both the other methods elevated for nearly an hour.

3. After the hot-water baths the temperature returns more slowly to normal than after air baths.

4. The pulse by the wrapping process is slowed, but, on the contrary, it is quickened after both hot-air and water baths, and so continues an hour after the bath.

5. Under the influence of wrapping, the respiration is slow; in the baths it is more frequent, but it returns more quickly to the normal than after swathing.

6. The most marked diaphoretic effect was produced by the hot-air and water baths; the least marked by swathing.

7. The baths were the more stimulating to the nervous system, and the swathing the more sedative, and the patients accordingly preferred the former as more energetic and as improving their condition.—*Centralblatt für die Gesammte Therapie*, August, 1885.

MENTHOL AS A LOCAL ANÆSTHETIC TO THE MUCOUS MEMBRANE OF THE THROAT AND NOSE.—DR. ALBERT ROSENBERG, experimenting with menthol, has found it to be a valuable anæsthetic to the nasal and pharyngeal mucous membranes, and, while not displacing, is a valuable supplement to cocaine for such purpose.

In his experiments with menthol, Dr. Rosenberg used a 20 per cent. ethereal solution, and in the seventy cases experimented upon up to the present time, after the use of the agent, a marked diminution in the sensibility of the parts. No inflammation or cauterization has been observed.

In some cases the anæsthetic effect results immediately after the application of the menthol, while in other cases it is observed after a half minute or longer.

The duration of the effects caused by the thymol is not so long as that resulting from the use of a 20 per cent. solution of cocaine, but always persists from a quarter to a half hour, and sometimes is prolonged an hour to an hour and a half. Cumulative effects also seem to result.

To avoid the pain produced by the application, the author employs a 50 per cent. alcoholic solution. He has also employed an oily solution of the strength of 30 per cent. with good results. A 20 per cent. ethereal solution causes great diminution in the sensibility of the throat, and sometimes complete anæsthesia. In two cases cauterization of the pharynx with chromic acid was practised after applying solution of the drug to the mucous membrane, without causing either reflex spasm or pain.

Dr. Rosenberg does not hold that menthol should displace cocaine as a local anæsthetic, but considers its use indicated,

1. In preliminary applications to the nose in order to determine whether a neurosis has its origin in this organ.

2. In cases where the sensibility of the nose is too great to permit operation, and where it is desired to diminish, as much as possible, pain and reflex movements.

3. In operation upon the pharynx, menthol may be substituted for cocaine, either to facilitate examination, or to render such procedure less painful.

4. Experiments hitherto made with the drug upon the larynx are not sufficiently conclusive to establish the extent to which it may be applied, although the sensi-

Digitized by Google

bility of the p: is diminished and respiration more easy, even in a subject affected with adduction of the vocal cords.—*Berliner med. Wochenschr.*, y 13, 1885.

OPERATION OF THYROIDECTOMY.—DR. T. F. CHAVASSE, in a clinical lecture, reviews the operation of thyroidectomy as follows:

Thyroidectomy having been decided upon, the following points must be considered: I. The question of prognosis. II. The method of operation to be followed. III. The dangers to life during and subsequent to the operation.

I. *Prognosis.*—1. With regard to age. The patient being young, the chances of a successful issue are more favorable. According to Billroth, after forty, a successful termination is very doubtful.

2. The larger the tumor the greater the risk to life, this being mainly due to the increased size of the various bloodvessels. There is also a probability of its adherence to the trachea, especially if the isthmus be a broad one, or of the growth passing backwards between the windpipe and the œsophagus, thus enhancing the difficulty of applying the necessary ligatures to the pedicles. If the goitre be limited to the isthmus of the gland the operation is much simplified.

3. Substernal goitre is very unfavorable for operation, as it can only be reached with extreme difficulty. Experience has shown that the more serious the symptoms of asphyxia, so much the less are the chances of success offered by ablation.

II. *Method of Operation.*—The earliest operations were performed by cutting down upon the gland, extirpating as rapidly as possible, and staunching the hemorrhage the best way the surgeons could.

An advance upon this method was that adopted by Vogel in 1771, in which all the main arteries supplying the goitre were ligatures beforehand, and the gland removed by a circular incision. Hedenus, of Dresden, who was the most successful operator at the beginning of this century, employed a median vertical incision, and the tumor was freed as far as the entrances of the thyroid arteries into the gland. A double ligature was then applied to each vessel, and a division made in the interspace. In spite of these precautions there was often great hemorrhage. If the tumor was attached to the thyroid cartilage or upper rings of the trachea, it was transfixed with ligatures, then another was passed round the entire base and the gland removed.

In a patient upon whom Graefe successfully operated in 1820, the procedure was divided into stages. The right superior thyroid artery was first ligatured. On another occasion the right lobe of the gland was removed. The patient left the hospital, subsequently returning, when the left upper artery was ligatured, and afterwards the left lobe was successfully taken away.

The late Warren Greene, Professor of Surgery in Maine, in 1866, advocated the following method: 1. A linear incision through the integument; avoid wounding the tumor or its fascia propria. 2. Divide the fascia upon a director in the median line. 3. Reflection of the same, and enucleation of the tumor with the fingers and handle of the scalpel, paying no attention to hemorrhage, however profuse, but going on as rapidly as possible to the base of the tumor, and compressing the thyroid arteries. 4. Transfix the pedicle from below upwards with a blunt curved needle armed with a double ligature, and tying each half, or, when practicable, dividing the pedicle into as many portions as there are main arterial trunks, and tying each half separately, and then remove the gland.

In 1871 Dr. P. H. Watson brought under the notice of the profession a mode of operating which he regarded as being rapid and nearly bloodless. For its accomplishment he laid down the following rules: 1. The external incision should be very free, extending from the larynx to the notch of the sternum if the tumor be large and spreads widely in a lateral direction; the vessels, arterial and venous, in this incision should be secured as they are divided, to avoid any obscuration of the parts through oozing. The fascia and skin should be equally opened. 2. The investing delicate fascial sheath of the thyroid gland should be left undivided until the mediate ligature of the vessels included in their fine cellular sheath has been effected. 3. Ligature of the thyroidal vessels in their sheathing cellular envelope by means of a double ligature. The cellular capsule is now opened in the middle line and the attachments, which still retain the goitre, are divided by blunt-pointed scissors.

The advantage of this method is, that the vessels of the gland, which have very frail walls are secured inside their sheath, and do not, therefore, so readily tear. On the other hand, the tendency of the ligature to slip after being secured is increased.

I would here remark that the so-called capsule of a bronchocele varies much in appearance and density; in fact, in one case operated upon by myself there was no semblance of such a texture.

Sir Joseph Lister has added to this procedure by applying additional ligatures by transfixing the pedicle in several places. By so doing the stump that is left is tied in separate bundles behind the ligature taking in the whole thickness. This plan adds somewhat to the time occupied in the performance of the operation, but the restraint of hemorrhage is certain. Even if the main ligature should slip at one or more of the secured angles of the tumor, the pedicle being split up into so many strands by accessory ligatures, no important bleeding can occur.

In a girl, aged thirteen, with a very large goitre, operated upon by the late Professor Spence when I was his house-surgeon in the Royal Infirmary, Edinburgh, at an early period of the operation a double ligature was carefully passed under the isthmus between it and the trachea, tightly tied, and the structure divided between the two. This simplifies matters, by allowing each lobe of the gland to be taken away separately, and the trachea is less likely to be injured.

Professor Lücke, of Strasburg, in his work on *Diseases of the Thyroid Gland*, advocates a median incision, and the pedicle, which is described as being rounded or plate-like, is to be ligatured *en masse* if thin; should it be thick, it is to be subdivided.

The late Professor von Bruns, of Tübingen, who ranks among the most successful of modern operators, directs his skin incision along the anterior border of the sterno-mastoid muscles. If more space be needed at

Digitized by Google

the lower extremity of this, a transverse cut is made across the neck; double ligatures are applied to the pedicles before removal.

III. *Dangers to Life During and Subsequent to Operation.*—In whatever manner the thyroid gland be extirpated, the operation cannot be undertaken without numerous risks. These may be (*a*) during the operation, or (*b*) during the after-progress of the case.

(*a*) Dangers during the operation: 1. "Hemorrhage" is the first danger that needs attention. This in the earliest efforts was the most usual cause of death, and so principally feared. By securing, before the actual ablation, the isthmus and four angles of this gland this danger has been minimized. 2. "Wounding the Trachea." This is especially liable to happen when the isthmus is adherent to the rings of the windpipe, and if the attempt be made to take away the whole gland at once. Should the trachea be opened, a tube must be at once inserted. The accident is one that tells considerably against a successful issue. 3. "Injury to the large nerve trunks." From the situation of the various nerves it would almost seem impossible to injure them, but cases are on record in which the accident has happened. In one of Dupuytren's, the operation having been completed, the patient had great difficulty in swallowing, rapid and difficult respiration, and constant sickness. Death took place in thirty-five hours. The post-mortem showed that the right recurrent laryngeal nerve was cut and ligatured. In another case of Klein's, during the operation the patient lost his voice and had dysphagia. In three weeks, however, the voice recovered somewhat, but ever afterwards remained a deep bass. In a patient of Billroth's, who died soon after the completion of the ablation, at the autopsy it was discovered that the recurrent laryngeal nerve was included in the ligature securing the inferior thyroid artery. Injury to the recurrent laryngeal may perhaps be accounted for by the fact that, in a large bronchocele, the trachea is frequently compressed and displaced. Hence the nerve in its passage to the larynx is more exposed than normal, and from its close connection with the artery is liable to be ligatured or divided when the bloodvessel is dealt with. 4. "The entrance of air into the large veins." This is an accident extremely likely to happen, as the veins are generally much enlarged. Double ligatures should, therefore, always be applied before any large venous trunk is severed. In a case of Klein's, where this accident happened, the patient died immediately. In one of my own, in which the internal jugular was torn low down on the left side just as the operation was being concluded, the man succumbed in half an hour.

(*b*) Dangers during the progress of the case, the operation being concluded: 1. "Shock." A considerable degree is always present in this operation, as the procedure is a lengthy one, and a clean dissection of the anterior portion of the neck is made; but when the patient has once rallied the after-progress is often rapid and satisfactory. 2. "Secondary hemorrhage." This is least likely to take place when Sir J. Lister's method of securing the vessels is adopted, for then the various vessels are secured by numerous ligatures. In one of Greene's cases operated upon by his own plan, the wound was kept open until reaction was fully established, and in a quarter of an hour the inferior thyroid artery escaped from its single ligature and spurted with great violence, necessitating transfixion of the pedicle with a tenaculum, and the application of another ligature. On the tenth day bleeding again occurred, and, in spite of digital pressure, continued for seventy-two hours, but then stopped. Eventually recovery took place. 3. "Suppuration." This following ablation of the gland may prove fatal in two ways: (*a*) By implicating the surrounding cervical textures and giving rise to œdema glottidis. In a fatal case of Mr. Spence's, occurring eighteen hours after the operation, post-mortem examination showed that an œdematous condition of the glottis existed even before suppuration had commenced. (*b*) By extension into the mediastinum, causing thoracic complications. The use of antiseptics in some form or other will do much to prevent this. 4. "Necrosis of the rings of the trachea." This is only likely to arise in bronchoceles very adherent to the windpipe. In three cases in which it happened, one was due to the application of Maisonneuve's constrictor, and another to the free application of a strong perchloride of iron to arrest hemorrhage. 5. "Septicæmia and pyæmia." Antiseptics lessen these dangers. In five of Billroth's fatal cases death occurred from blood-poisoning. In a private communication my former teacher tells me that if antiseptic precautions had been used in all his cases the mortality would have been greatly lessened. 6. "Syncope." Up to the present time this, as far as I can ascertain, is an unrecognized danger. On August 14, 1884, I removed a bilateral goitre, weighing nine ounces, from a girl, aged eighteen, with very marked symptoms. The patient rallied well from the operation, and two hours after its completion expressed herself as being comfortable. A quarter of an hour later she died suddenly in a state of collapse. The post-mortem examination showed that all the angles of the gland were securely ligatured. As far as could be ascertained after careful search the pleura was intact. However, both lungs were found to be completely collapsed. The cardiac cavities were contracted and empty. In the posterior mediastinum bubbles of air were seen; these could readily be traced down the spine into the abdomen. The subperitoneal fascia there was found to be emphysematous, and the fascia in the iliac fossa was greatly distended with air. Death was, I presume, due to syncope caused by the presence of air, which had gained access during the separation of the thyroid gland from its capsule and surrounding tissues.

My personal experience of thyroidectomy is limited to twelve cases. From these I would make the following deductions: 1. The operation is a grave one, and should not be lightly undertaken, especially as our knowledge of the exact functions of the gland are at present somewhat hazy. 2. I is better to remove one lobe at a time rather than to attempt excision of the whole gland. It is probable that such a procedure will sufficiently relieve all urgent symptoms. 3. That if a capsule exists it should be opened in the median line, and that the angles of the gland should be firmly secured before the goitre is enucleated; that it is best to ligature first the angle of the gland containing the superior thyroid artery, next the isthmus, and to take away

Digitized by Google

the gland from above downwards, ligature of the inferior thyroid angle being one of the final steps of the operation. 4. That stout carbolized silk is the most reliable material for securing the pedicles. 5. That antiseptic dressings in some form should be employed. 6. That the success of the operation will probably increase with the experience of the operator.—*The Lancet*, July 18, 1885.

THE REGULATION OF PROSTITUTION.—DR. MARTINEAU, at a recent meeting of the Société Obstétricale et Gynécologique de Paris, presented the following conclusions relative to the control of prostitution. He considers as necessary—

1. To keep surveillance over, to restrain, and repress by laws and regulations, old or new, the practice of clandestine prostitution, which is more active in the propagation of syphilis than open, regulated, and legalized prostitution.

2. To compel from legalized prostitutes more frequent medical examination—every three or four days.

3. To suppress medical visits at the residence of prostitutes, except in certain determined cases.

4. To increase the number of dispensaries and of physicians in this service.

5. To suppress the infirmary of the prison Saint-Lazare for legalized and clandestine prostitutes affected with syphilitic disease.

6. To create a special hospital for legalized prostitutes, the hospital of Lourcine being reserved for clandestine prostitutes.

7. To create in the hospital a special service for suspected patients.

8. That the hospital be apart from police supervision, and be managed by the municipal authorities.

9. That the physicians of the dispensary be appointed by competitive examination.

10. That medicine and baths be given to syphilitics in outside consultation with the hospital.

11. An apartment reserved in the hospital specially for women under criminal charge when suffering from venereal disease.

12. To make visits to the hospital obligatory to every prostitute as soon as she finds herself diseased. These visits will not result in the registry of the woman upon the lists of authorized prostitutes.

13. To retain in the infirmaries of the prisons until completely cured all men affected with venereal disease. This power being devolved upon judicial authority only, based upon a medical certificate certifying the nature of the disease.

14. The suppression of pandering, etc., by rigid laws.—*Archives de Tocologie*, August 1, 1885.

MODES OF POISONING BY SULHURETTED HYDROGEN.—MM. P. BROUARDEL and PAUL LOYE, having observed that workmen poisoned by sulphuretted hydrogen frequently died after having exhibited very dissimilar symptoms, have investigated the modes in which the agent destroys life, and reach the following conclusions:

1. It appears legitimate to distinguish two forms of poisoning by sulphuretted hydrogen.

2. In the first form death is sudden, and seems very clearly due to an action of the gas upon the nervous centres.

3. In the second, death results slowly, and to the nervous phenomena are joined symptoms which seem related with asphyxia.

4. The mode of poisoning varies with the amount of sulphuretted hydrogen present in the inhaled air. A dog, after inhaling five litres of air containing 2 parts to 100, died in two minutes. A second dog died at the end of three-quarters of an hour, after inhaling 100 litres of air, containing one-half of one per cent. of the gas. Absolute quantity of the gas is, therefore, of less importance in poisoning by it than the degree of its tension in the air.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, August 7, 1885.

EXPERIMENTAL RESEARCHES UPON FRACTURES OF THE BASE OF THE SKULL.—WILHELM GREDER, in experimenting upon fractures of the skull, with weights ranging from 200 to 240 pounds, let fall from a height of four feet upon the heads of cadavers, has arrived at the following conclusions:

1. Solutions of continuity of the base of the cranium, so far as concerns longitudinal, transverse, or oblique fractures, should be considered as fissures the result of a species of rupture.

2. The direction of the fissures is parallel to that of the pressure exercised.

3. The extent of the fractures depends upon a great number of conditions, variable in each skull and each experiment, and cannot be supposed to depend only upon the violence of the blow.

The most practical result obtained is that from the direction of the blow, the probable direction of the fracture can be deduced, and consequently determined, the organs receiving and escaping injury. Inversely, the medico-legal expert can deduce the direction from which the blow proceeded according to the direction of the fracture.—*Deutsche Zeitschr. für Chirurgie*, 1885, Bd. xxi. Hft. 5 and 6.

EXPERIMENTS IN BACTERIO-THERAPEUSIS.—PROF. ARNALDO CANTANI, of Naples, in view of the fact that other bacteria are destructive of Koch's tubercle bacillus, has recently made some experiments relative to the therapeutic treatment of tuberculosis by means of the bacterium termo. He first found by experiment that the bacterium termo, whether inoculated, inhaled, or injected, exercises no harmful influence upon the tissues of living animals. He then caused a spray of fluid containing this bacterium to be inhaled by a patient suffering from tubercular disease of one lung, whose sputa contained tubercle bacilli in large quantities, as shown by the microscope, and also by the results of injection practised upon small animals.

These inhalations continued daily for a month, were followed by the rapid improvement of the patient, especially in the local conditions.

The sputa, examined at frequent intervals, were found to become less and less rich in the bacillus tuberculosis, but were full of bacteria termo, and their injection into the lower animals failed longer to produce tuberculosis.—*Centralbl. für die Medicinisch. Wissenschaften*, July 18, 1885.

MICROBES OF SYPHILITIC ULCERS.—At a meeting of the Académie de Médecine de Paris, held August 4, 1885, M. CORNIL made an interesting *résumé* of the investigations of MM. Alvarez and Tavel upon the microbes of syphilitic ulcers. The report of the investigators is the following:

1. There exists in some of the normal secretions of the body a bacillus, which, up to the present time, has not been pointed out.

2. This bacillus is identical in form and in its behavior with coloring agents with that which Lustgarten has described as the special bacillus of syphilis.

3. It is possible that the bacillus which Lustgarten has found in sections of syphilitic growths and in syphilitic secretions is this common bacillus.

4. Our bacillus is very similar in form to the bacillus tuberculosis, and presents many of the coloring reactions which hitherto have been considered as peculiar to Koch's bacillus, and to that of leprosy.

5. It is distinguished from the bacillus of tuberculosis by being less thick, and of a less granular appearance (conditions difficult to appreciate in a single examination), by its inferior resistance to alcohol, after staining with fuchsine and treatment by nitric acid. It is further distinguished, by its failure to be stained by methyl-violet, according to Ehrlich's method.

6. In the clinical diagnosis of tuberculosis, made by microscopical examination of secretions, these facts should be held in mind.—*L'Union Médicale*, August 6, 1885.

CONGENITAL DEFECT OF THE HEART.—VON ELLENGER, in the *Archiv für Kinderheilkunde*, Bd. vi. Hft. 2, records the annexed congenital defect of the heart. The child in which it occurred was fourteen days old. Impulse of the heart was to the left at the fifth and sixth intercostal spaces, and in the mammary line, with apparent enlargement of the heart in its long axis. The pulse varied between 60 and 76. At all four cardiac orifices an apparent systolic murmur was heard, though no normal heart sound was perceptible. In the interscapular space a murmur was also audible, but insignificant. Intense cyanosis of the face existed, and a pneumonic condition was slowly developed. The cyanosis increased and hemorrhages occurred in various parts of the body. The heart symptoms also became more marked, and death resulted at the age of two months.

Post mortem showed the following: Transposition of the aorta and pulmonary artery; muscular stenosis of the arterial cone; persistence of the foramen ovale, and a pervious condition of the ductus Botalli; defect of the septum ventriculi, and double broncho-pneumonia.—*Centralbl. für klin. Med.*, July 8, 1885.

INCISION OF THE PERICARDIAL SAC IN SUPPURATIVE ENDOCARDITIS.—DR. E. A. MICHAELOFF, in *Medizinskoje Oboerenje*, 1885, No. 5, reports the case of a woman, aged thirty-five years, who entered the hospital with symptoms of suppurative pericarditis.

The liver was enlarged; there were anasarca, albumen in the urine, and general emaciation. Increasing dyspnœa, cyanosis, and weak pulse, together with complete inability to sleep, made puncture of the pericardium necessary. The operation was accordingly done, and the needle introduced at the fourth intercostal space. Puncture resulted in the escape of nearly three ounces of pus, followed by half the quantity of almost pure blood. Inasmuch as improvement continued for only a short time, on the second day an incision was made, four-fifths of an inch in length, close to the sternum and in the region above indicated. After removal of about a quart (two pounds) of blood-colored, bad-smelling pus, the pericardial sac was washed with a solution of resorcin, and drainage established. Immediately after the operation good effects were manifested. the dyspnœa disappearing, and the frequency of the pulse diminishing from 120 to 90. Improvement was, however, only temporary, and the patient died in eighteen hours in collapse. Post mortem revealed the presence of fatty degeneration of the heart, with dilatation, marked right hydrothorax, chronic perimetritis, and a general marasmic condition.—*Centralbl. für Chirurgie*, July 4, 1885.

A CONTRIBUTION TO THE OPERATION OF RESECTION.—DR. EMILE BOUCHEZ, in an original paper on the results of operation for resection, arrives at the following conclusions:

1. The mortality was *nil*, excepting one case, in which it was insisted upon by the patient, although contraindicated by an osteomyelitis of unknown extent.

2. The reëstablishment of general health after the operation was immediate and remarkable. Emaciation gave place to *embonpoint*, and by the second month exercise in the open air was possible.

3. Bony anchylosis and good position in two cases operated on for scrofulous tumor of the knee gave excellent results. In one case an apparatus was necessitated. The result was only passable. In three cases—Arabs—the ulterior results are unknown.

In a case of fungous and suppurating osteoarthritis of the wrist prehensile movements of the fingers are still possible, and the author believes that the periarticular swelling and infiltration of the tissue will disappear with time.

The cases on which these observations are made include three resections of the knee, one of the hip, one of the shoulder, one of the elbow, and one of the wrist.—*Archives de Médecine et de Pharmacie Militaires*, Aug. 1885.

NUTRITION WITH MEAT PEPTONES. — DR. EMIL PFEIFFER, after an experimental study of the value of meat peptones as an article of food, vouchsa es the following conclusions. He says: Both peptones (Koch's and Kemmerich's) possess great value as nutrients. The preparation of Koch has no superiority over that of Kemmerich. On the contrary, the preparation of Kemmerich is better applicable in cases of overfeeding, as also in cases of insufficient nutrition, because it produces in the first a greater residue, and in the second a marked diminution of the nitrogenous loss. Through its greater solubility in water, and on account of its more pleasant taste, Kemmerich's preparation has practical advantage over that of Koch.

The larger doses required of Koch's preparation, and the possible intestinal irritation and diarrhœa thereby caused, will greatly diminish the general use of this peptone.

Kemmerich's meat preparation is well adapted to use *per enemata*.—*Berliner med. Wochenschr.*, July 27, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, AUGUST 29, 1885.

THE INTERNATIONAL MEDICAL CONGRESS.

THE majority of the physicians of the United States who have followed the progress of affairs in regard to the Congress, will probably assent to the following propositions:

1. The Congress is a purely scientific body, having nothing whatever to do with ethics or medical politics.

2. The invitation to the Congress was not given as coming from the American Medical Association, and it was not accepted by the Congress with the understanding that the meeting would be under the special patronage and control of the Association, or of any other medical society.

3. The Original Committee of eight was fully authorized by the resolutions which created it, to add to its membership, and to proceed with the work of organization without special reference to the American Medical Association.

4. The enlarged committee formed by the Committee of eight effected an organization which was satisfactory to the Executive Committee of the International Congress, and which bid fair to make the meeting a great success.

5. The action of the American Medical Association at New Orleans, in refusing to accept this organization, and in assuming control of the whole matter, was discourteous to the Congress, and injurious to the reputation and interests of the medical profession of the United States.

6. This action, and the action of the Committee of the Association, have given rise to great dissatisfaction both in this country and abroad, so much so, that if they are persisted in there is very great danger that the Congress will not hold its next meeting in this country.

7. The honor of the medical profession of the United States demands that through no act of theirs shall the agreement be set aside, by which the Congress at Copenhagen in 1883 was led to accept the invitation to meet at Washington in 1887.

Now in view of these facts what is the duty of the Committee of the American Medical Association?

The so-called proposals for compromise which we have heard of, such as allowing all societies to send members, or even delegates, provided no New Code man is allowed to hold office, will, if adopted, simply make the injustice more glaring, because they are a practical acknowledgment of the fact that the Congress is a purely scientific body, and that medical politics should not enter into its organization—while, at the same time, they introduce politics in the form of an offensive discrimination against some of our best known physicians. Such a proposition, if adopted, would simply prove an additional source of irritation, and do no good whatever.

When we consider the fact that the leading Old Code men in New York meet the New Code men freely in consultation; and that the Editor of the *Journal of the American Medical Association* and Dr. Jacobi, of New York, have been working together as the American Committee of the international organization for collective investigation, it surely needs no argument or illustration to prove that the ignoring of the Code question in the International Congress is in no way derogatory to the dignity of the American Medical Association, or to that of any member of it. This was the view that was taken by the original enlarged Committee, and its wisdom will be agreed to in the future by those who have been most violent in condemning it.

The American medical profession wants to have a large and successful Congress; it wants the leaders of European medicine to be present at it; it wants its own best observers, experimenters, and thinkers to present their work at the sessions, and obtain the honor which is their due; and it is to those who thus participate, and to those only, that the laurels of the Congress will fall.

The members of the new Committee have carried out their instructions, and have tried to organize the Congress; they signally failed at the outset because it was recognized that the reason of its existence was disappointed personal ambition, and because their leaders did not possess the confidence of the profession at large. Over one hundred and twenty-five of the most eminent of their appointees, representing every section of the country, declined to accept office under them. The withdrawal from all official connection with the Congress of such a large proportion of the most distinguished mem-

Digitized by Google

bers of the profession in America has had the effect of creating a strong sentiment among the profession in Europe that, unless the arrangements for the holding of the next Congress are placed in the hands of men whose names are an international guarantee of the success of the meeting, the authority of the Executive Committee should be exercised, and the meeting of the Congress in 1887 be held not in America, but in some other country, to quote the language of the London *Lancet*, "in which the medical profession will not find it impossible to combine for international purposes."

Since their appointment by the American Medical Association, the New Committee have learned that the Association has no authority to organize the Congress. Now self-respect, the honor of their country, and their duty to the International Medical Congress, alike demand that they shall decline to continue their work of organization, and that they shall take the straightforward, manly course of declaring that the Association has made a mistake, due to insufficient information and a misunderstanding of the rules and wishes of the Congress, and that they make way for a Committee which shall possess the requisite authority and which can command the respect and support of the profession both at home and abroad.

HOT WEATHER DIETETICS.

IT has been aptly suggested that the relation of a human body to its constituent element is closely analogous to that which a dissected map bears to its parts, each of which must be exactly fitted in its proper place, or else the whole design is rendered imperfect. Doubtless many of the chronic derangements of health which entail so much suffering upon humanity, are due to the incomplete supply, by food, of some minute yet important ingredient, the absence or deficiency of which, like the loss of a correspondingly small portion of the divided map, mars the perfectness of the entire structure.

Not only must the human organism be built up in the first place, with its necessary components in precisely their requisite quantity and arrangement, in order to constitute a complete whole, but for the further maintenance of health these essential elements must be continually replaced as they become effete, from the constituents of our diet, in exactly the right proportion. Hence, the vital necessity imposed upon us all, of so regulating the food we eat, in correspondence with varying external conditions of the environment, as to fulfil this law which ordains that for every atom of tissue worn in the vital processes, another atom must be conveyed into the system as food, dissolved in the digestive apparatus, and transmitted in a liquid form to the blood, in which it is carried to the remotest recesses of the system, and assimilated into the tissues during the unceasing operations of repair.

If mankind were constantly subjected to the action of the same temperature and humidity, of the same amount of exercise, of similar periods of repose, and of other similar minor modifying influences, a standard bill of fare, adapted to all divisions of the year, might, perhaps, be agreed upon. But since the ever-varying conditions of existence continually change the amount and kind of tissue waste, and as the different seasons roll round in their appointed course, it is evident that naught but a watchful compliance with the varying physical requirements can secure the most appropriate renewal of life, and, therefore, the most prolonged retention of perfect bodily health.

If we consider the alterations which elevation of temperature renders judicious in regard to the supply of ingesta for the human organism, we find that one of the most important modifications of diet, which is advisable during the summer months, is a reduction of the fatty or heat-producing, and of the nitrogenous or muscle-forming materials, in correspondence with the diminished activity in the processes sustaining the animal temperature. In cold weather the loss of caloric is so rapid, that large quantities of carbonaceous matter must be burnt up, in the innumerable, tiny, atomic stoves of the body, to preserve the standard heat of 98.4° Fahr. But when the external air approximates to this temperature, radiation and conduction proceed, of course, much less speedily, and such a relatively great amount of fatty and nitrogenous food being uncalled for and unconsumed, overloads and oppresses the digestive apparatus. The experience of Englishmen in India is very conclusive upon this point, and one of Becquerel's excellent rules for visitors to hot climates, is that they should scrupulously confine themselves to a comparatively scanty and unstimulating diet, avoiding in great measure such articles of food as fat meat, eggs, cheese, etc., during the continuance of the warm season.

On the other hand, just as an excess above the average amount of heat-producing elements should be partaken of in winter, so an augmented quantity of watery fluids, and of succulent fruits or vegetables, ought to be ingested during the summer. A very important part of the wonderful heat-regulating function of the organism is accomplished by the elimination of moisture from the skin and lungs, which, in the process of vaporization, carries off the excess of heat, so that an abundant supply of water, either in food or drink, is ordinarily one of the imperative necessities throughout the summer months. Hence the ingestion of cool water, in small quantities frequently repeated, of mildly subacid fruits,

Digitized by Google

such as strawberries, blackberries, peaches, or melons, and, under appropriate restrictions, of such vegetables as fresh potatoes, corn, tomatoes, raw cabbage, celery, and similar articles of diet, is as a rule highly conducive to health. Few persons indeed realize the vital necessity which exists during exposure to high temperature, for a very frequent and systematic imbibition of fluid, to keep up this abundant flow of perspiration from the skin, and we feel assured that had this urgent demand for cool water been properly understood and duly complied with, such an extraordinary mortality from "sunstroke" during the late heated term, of forty-seven fatal cases in a single week, would not have appeared in our death-register. The value of a continuous supply of small draughts of water, as a prophylactic against sunstroke, was often illustrated in the late war during the summer marches of the Army of the Potomac. Dr. Smart tells us, "if the water in the canteens lasted until the next opportunity of refilling them, so that ingestion and transudation were equalized, the men pushed along, faint from fatigue perhaps, but in no danger from sunstroke. If on the other hand the supply failed, and the skin became dry, danger from sunstroke was imminent."

Many of our summer fruits, consisting, as they frequently do, of from seventy to ninety per cent. of water, constitute delicious substitutes for frequent draughts of aqueous fluid; but, even the fruits and vegetables which usually prove wholesome, are exceedingly apt, if freely partaken of when they first make their appearance, and before people have grown accustomed to their use, to cause disorder of the bowels, and, as is well known, sometimes to set up violent, perhaps fatal, cholera morbus. Whilst, therefore, it is very important to approach gradually free indulgence in the feast of luscious fruits which nature bountifully provides for us even in ordinary seasons—the chance of a cholera visitation should render us particularly cautious this year, because diarrhœal disturbance not only makes an individual far more liable to contract cholera, should that epidemic disease synchronously prevail, but, to the usual danger, adds the liability, which cases of cholera developing from a preëxisting diarrhœa possess, of being far more apt to prove intractable and fatal. Hence, should fruit and vegetables display a tendency to cause looseness of the bowels during our heated term, which often runs far into September, the necessary amount of liquid to supply the demands of the heat-regulating apparatus of the organism ought to be imbibed in the form of well-boiled and filtered water, cooled with pure ice, of weak iced-tea, or of some analogous beverage.

Of course, if Asiatic cholera, in spite of all our precautions, actually does make its outbreak this year upon the North American continent, prudence dictates that every article of diet consumed during warm weather should be purified from the living germs of the comma-bacillus by heat—that is, by exposure for at least half an hour to the temperature of boiling water, *as short a time as is practicable before it enters into the human stomach.*

PHYSIOLOGICAL ALBUMINURIA.

WHETHER or not, in strict accuracy, there be such a thing as physiological albuminuria, there can be no doubt that it occasionally happens that albumen is present in the urine of those who exhibit no other symptoms whatever of renal disease. There are three separate varieties of this condition: The albuminuria of the newborn, which approximates more nearly than any other form to a true physiological albuminuria; the albuminuria of adolescence; and the albuminuria of otherwise healthy mature men.

First, as to the albuminuria of the newborn. Virchow, Dorn, Martin and Ruge, and Hofmeier, have all called attention to this condition. Hofmeier says it is almost invariably present in the newborn. According to Ribbert, albuminous urine is secreted by the fœtus, and disappears a few days after birth. It is explained by Ribbert that in the fœtus and newborn child the epithelium which covers the glomerule is not flat and invisible as in the adult, but cubical, and the cells are protoplasmic, more like gland cells, and, like the latter, they separate albumen, while the office of the flat endothelial cells in the adult is to retain the albumen and to permit the water, only, of the blood to filter out.

Rosenbach, on the other hand, suggests that at the time of birth many corpuscles disintegrate, and that the albumen thus liberated, being superfluous, is secreted by the kidneys and appears in the urine. Senator, in *Berliner klin. Wochenschrift* for April 20, 1885, is inclined to attribute the condition to a number of causes, of which the most important is the sudden increase of vascular pressure which takes place in the glomeruli at the moment of birth. At the same time begins an abundant loss of water from the skin and lungs, as the body passes from the influence of the surrounding amniotic liquor into that of the atmosphere. These, with the increased amount of albumen due to the disintegration of blood corpuscles already referred to, and perhaps also an increased proportion of salts, are sufficient to cause the albuminuria, or to increase that already existing, during fœtal life. Within the first five days of life, however, the conditions change. The loss of weight which immediately succeeds birth, is first compensated, then the weight goes on increasing, the blood becomes more watery, the urine increases in quantity and is reduced in specific gravity from 1010 to 1006 and 1004, and the albuminuria disappears.

Digitized by Google

The albuminuria of adolescence less justifies the term physiological. Occurring more particularly in young men from fifteen to twenty years old, it is not always unassociated with other symptoms. There are often rapid growth and development, and a feeling of debility not infrequently accompanies these. It is even less easily explained than the albuminuria of the newborn. The large demand made upon the albumen of the blood at this period of life for the purposes of growth and development, produces a state the reverse of that assigned as a cause in the newborn infant, a thinness of the blood. This may be excessive, and lead, especially in connection with a feeble propulsive power of the heart and a defective nutrition in the kidney, to a transudation of albumen-containing fluid. Doubtless some of the causes which will be next mentioned as responsible for the albuminuria of adults, may also operate with the adolescent youth.

The last variety deserves, least of all, the term normal albuminuria, although it is so often unaccompanied by any other symptoms of ill-health. An increasing number of such cases is daily reported, but although, according to Senator, albumen is found in the urine of from ten to twenty per cent. of apparently healthy adults, we insist that it cannot be regarded as a normal phenomenon. Certainly he who has it, is not so well off as he who has it not, and while active treatment may not always be judicious, yet there are many acts in life which may be performed without risk by one in whom the condition does not exist, but which should be avoided by the subject of such an albuminuria.

These albuminurias are always small, and sometimes accompanied by a few hyaline casts. Among the conditions sometimes associated with them, and which may be said to be more or less responsible for them, are great muscular activity, the ingestion and digestion of highly albuminous foods, mental excitement, and cold bathing. Hence such albuminurias are often intermittent. They may be sometimes due to vaso-motor derangements, but the instances in which these causes can be pointed out as responsible are very few.

The effect of cold baths in producing albuminuria has scarcely excited sufficient attention, and the fact that they do produce it is too often overlooked by physicians in their advice to patients concerning bathing. Long-continued immersion, of course, tends more strongly to produce it, and an existing albuminuria, whether it be of the kind called normal, or the result of recognized renal disease, emphatically and totally contraindicates cold bathing.

CONDUCT OF THE THIRD STAGE OF LABOR.

PROCHOWNICK communicates to the *Centralblatt für Gynäkologie* a paper upon the management of the after-birth period. Referring to the recent criticisms of Credè's method, he states that in none of these was included the objection, which he regards as the most important. This is the pain that the method causes, and the unwillingness of some patients to submit to it; while, it may be urged, the majority of women would not complain, yet many nervous, sensitive women would. Our own opinion, on the other hand, is, that this suffering, usually, is not great—certainly not as great as that which was endured for hours in the previous stages of labor—and is so brief that few object.

Prochownick gives his own method as follows: Immediately after the birth of the child the flat hand is laid upon the woman's abdomen, and, after the lapse of a few minutes, slight friction is made upon the fundus for the exciting of energetic after-pains. After the third uterine contraction has taken place, he asks the patient to flex her lower limbs, placing the soles of her feet against the foot-board, and make an expulsive effort, which in primiparæ raises the accoucheur's hand, which frequently in the parous sinks down between the recti muscles, that have been separated by pregnancy. If the placenta is not expelled, this must be repeated once or oftener, even to the seventh contraction. He states that in only one case did he have to wait longer than the seventh contraction. He is favorable to the use of ergot at the close of, or just after, the second stage of labor.

We believe the hand which is applied to the abdomen should not be flat, but concave—the manual concavity fitting to the uterine convexity—for then the uterus is defined, limited, a larger surface embraced, and any relaxation of the organ prevented, or at once recognized and remedied. Besides, a flat pressure, acting only upon the anterior wall, may, if this be greatly relaxed, so depress it as to prepare the way for uterine inversion. Certainly the part of Prochownick's plan which makes the woman a voluntary participant in the expulsion of the placenta, is good.

REVIEWS.

THE CLIMATE OF CANADA, AND ITS RELATIONS TO LIFE AND HEALTH. By WM. H. HINGSTON, M.D., D.C.L., etc., Surgeon to the Hôtel-Dieu, Professor of Clinical Surgery Montreal School of Medicine. Pp. 200. Montreal: Dawson Bros.

IT is not often we are so agreeably disappointed as we have been in this book. Instead of a mass of dry statistics and meteorological tables, which the title had led us to expect, we found an exceedingly interesting and instructive volume, in which the weary details of the observatory have been "digested and assimilated" and interwoven with so many and varied observations on geographical, hygienic, social, and ethnological questions, that the whole forms a contribution which will be of great value to any one seeking information about

Digitized by Google

Canada. Part I. deals with the physical geography and the climate, considered under the four seasons; Part II. with the relations of climate to health and life. In the latter the prevalent diseases and mortality are carefully reviewed. Perhaps the most interesting sections are those referring to the natural history of the French Canadians, the remarkable fecundity of the women, and the vigor and endurance of the men. Tables are given of the height, weight, and lumbar strength of the English and French-Canadian medical students, which show the former to be somewhat taller, but not so strong as the latter. It is a pity that fuller anthropometric observations have not been made, as it would appear that Canada offers a particularly suitable place in which to study the development of the English, Irish, and French races. Conclusions from the examination of a few hundred of individuals are not worth much, as can readily be seen by comparing the author's older and more recent tables. In the latter the lumbar strength of the British-Canadian students was greater than in the French-Canadian of the first series, and there seems to have been an extraordinary rate of increase in lumbar strength during the twenty-five years which elapsed between the observations, an average of 53 pounds in the case of the English and 48 pounds in the French students.

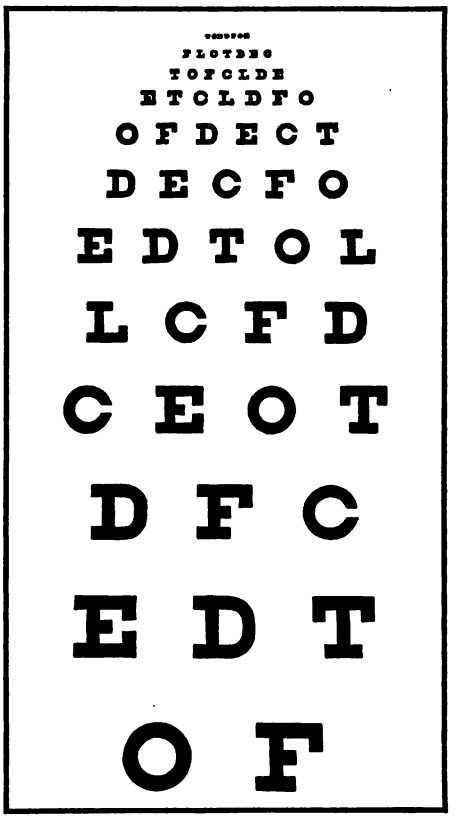
The work contains much matter of general interest, and is written in such a pleasant style, and contains so many references to social and racial problems, that it is certain to find a wide circle of readers. A table of contents and an index would have increased the value of the work.

NEW INVENTIONS.

A NEW SERIES OF METRIC TEST-LETTERS FOR DETERMINING THE ACUITY OF DIRECT VISION FOR FORM (BASED UPON SNELLEN AND DE WECKER).[1]

BY CHARLES A. OLIVER, M.D.,
ONE OF THE OPHTHALMIC AND AURAL SURGEONS TO ST. MARY'S HOSPITAL, PHILADELPHIA.

A SHEET of test-letters was exhibited which showed advantages not possessed by any other single form of test-card; these are as follows: *First, the Letter.* The Snellen basis of letter formation is accurately preserved throughout. Block letters are used. Each letter embraces a square area included in a five minute angle for both height and breadth, each stroke is one minute angle in width, and each spacing in the breaks and openings is of one minute angle or more. The nine letters C, D, E, F, L, O, T are used, as they alone fulfil the above conditions. *Second, the Sequence.* Four letters are composed of vertical and horizontal strokes and three are made of curved ones, thus giving a series which contain radii at all angles. Nearly every line has a combination of such strokes, so disposed as to make a letter of vertical and horizontal strokes follow a letter of curved ones; this order being rendered incomprehensible to the patient by a system of irregular



placing. Each line thus serves as an important adjuvant in the detection and the correction of astigmatism. *Third, the Interspace.* Each letter is surrounded by a free space which is greater, or at least equal, to its own area. The reasons for this are obvious. *Fourth, the Gradation.* To avoid unnecessary mental effort by the use of irregular fractions and to render computation quick, $\frac{5}{5}$ instead of $\frac{6}{6}$ has been assumed as $\frac{1}{1}$. The order is as given below.

This scale was partially made use of by De Wecker, but unfortunately it never gained sufficient popularity to be universally employed. The advantages are great, and can be compared with the superiority that the decimal system of coinage possesses over other methods of money valuation. *Fifth, the Reverse Order.* This arrangement saves time by the lack of necessity of the patient reading many letters before the proper line is arrived at, and allows a more correct answer, by reason of the eye not becoming fatigued.

$\frac{1}{2}$,	$\frac{1}{1}$,	$\frac{3}{4}$,	$\frac{1}{2}$,	$\frac{1}{3}$,	$\frac{1}{4}$,	$\frac{1}{5}$,	$\frac{1}{6}$,	$\frac{1}{7}$,	$\frac{1}{8}$,	$\frac{1}{9}$,	$\frac{1}{10}$.
$\frac{\text{II}\frac{1}{11}}{\text{V}}$,	$\frac{\text{V}}{\text{V}}$,	$\frac{\text{V}}{\text{VII}\frac{1}{11}}$,	$\frac{\text{V}}{\text{X}}$,	$\frac{\text{V}}{\text{XV}}$,	$\frac{\text{V}}{\text{XX}}$,	$\frac{\text{V}}{\text{XXV}}$,	$\frac{\text{V}}{\text{XXX}}$,	$\frac{\text{V}}{\text{XXXV}}$,	$\frac{\text{V}}{\text{XL}}$,	$\frac{\text{V}}{\text{XLV}}$,	$\frac{\text{V}}{\text{L}}$

[1] Abstract of a paper read before the American Ophthalmological Society, July 15, 1885.

The cards are manufactured in the following manner: The size of No. L type is estimated, and India-ink sketches of the seven selected letters are drawn to that

NEWS ITEMS.

MONTREAL.

(*From our Special Correspondent.*)

THE SMALLPOX EPIDEMIC.—During the last month smallpox has increased enormously. It is confined chiefly to the French part of the city, and the deaths that occur are almost altogether among the French. They neither vaccinate nor take any precaution to avoid infection, many even exposing their children to the disease intentionally. As the disease is sent by "*Le bon Dieu*," they say, of what use is it to take any precautions. In the French parish church, the other day, was a large meeting of people to pray God that the scourge might be removed, and on that occasion the officiating priest distinctly told the people that the smallpox was sent by the Deity on account of the sinfulness of the people. He called on them to repent and lead better lives, as the only means of staying the disease, but not a word was said of vaccination or other means of prevention. Although there is a great deal of smallpox here, the reports outside are very much exaggerated, and the panic is quite out of proportion to the extent of the disease. The death of Sir Francis Hincks from smallpox, a few days ago, has done more to arouse the people to a sense of their danger than would the death of a hundred insignificant individuals.

There are probably at present in the city about 500 cases of smallpox—not as much as there was five or six years ago. The civic hospital, which only contains 50 beds, is full, of course. The deaths for the past month have been over 100, and, with two or three exceptions, all amongst the French. There is no doubt, however, that the disease is increasing, and the health authorities are waking up to the fact. Public vaccinators have been appointed, and all the large warehouses and manufactories are compelling their employés (who are chiefly French) to choose between vaccination and dismissal. The English-speaking people are flocking to their physicians to be vaccinated, and it is difficult to get sufficient lymph to supply the demand.

Amongst the French there is, however, little stir, and but little is being done in the way of vaccination, except with those connected with the large establishments and manufactories, which are controlled by Englishmen and English capital. The French physicians are very lukewarm about the benefits of vaccination, and not a few are actively opposed to it. Unless the Roman Catholic Church takes up the subject and preaches vaccination and isolation to its people, the smallpox will remain with us till it wears itself out, in spite of the efforts of the health board and the English-speaking population. For four years we have been free from the disease, and the amount of virgin soil the disease will have to work on may be imagined.

FAITH CURES.—As usual at this time of the year, pilgrimages to St. Anne de Beaupré, below Quebec, are very numerous. Every pilgrimage is, of course, accompanied by priests and pious physicians, and many cures result from the prayers of the faithful before the shrine. As a rule, these cures are in hysterical girls, and are not much to be wondered at. In fact, for certain forms of hysteria in pious young girls, when other methods fail, a pilgrimage to a holy shrine, or a visit to the faith conventions, is often attended with marvellous results. I often wonder that this remedy is not mentioned in our standard works on therapeutics. The last pilgrimage to St. Anne de Beaupré accomplished, strange to say, only one cure, and that not a hysterical one. It appears that a boy who had for years been unable to walk without crutches, and who had had "running sores" in his leg, on visiting the shrine threw away his crutches, and the sores healed up instantly, and he was able to walk. This cure was certified to by several French physicians, who said that not only were the sinuses healed, but that in the healing the linen that covered them was thrown into the sinus and was with difficulty afterwards separated. On coming to the city, the newspaper reporters got hold of the case and asked a physician of repute to examine the boy for them. He did so, and found the case was an old one of hip-joint disease with ankylosis, that no doubt the patient did shuffle along in a way without his crutches, but that he could have done so had he tried before he went to St. Anne, as there was nothing to prevent it. As to the sinuses, some were healed certainly, but others were still discharging thin, watery pus through small openings, and that the disease still existed. Why should the good St. Anne not do her work more thoroughly? is the question asked by the wicked sceptics.

NEW BRUNSWICK MEDICAL SOCIETY.—The fifth annual meeting of this Society was held at Fredericton, on July 21st and 22d, the President, Dr. Walker, in the Chair. The following were elected officers for the ensuing year:

President.—Dr. P. R. Moore, of Sackville.
First Vice-President.—Dr. Coulthard, of Fredericton.
Second Vice-President.—Dr. Thorne, of Havelock.
Secretary.—Dr. Musgrove, of Carleton.
Corresponding Secretary.—Dr. Bruce, of St. John.
Treasurer.—Dr. D. E. Berryman, of St. John.

HOW CHOLERA SPREADS IN SPAIN.—*The Medical News*, Madrid, August 4, states that the Commission recently sent into the infected districts of Spain report that in all the villages they were able to visit they found the same clinical characteristics of the disease; that in the towns supplied with water from springs or wells cholera either did not prevail at all, or to a very limited extent, while in the towns supplied with water from streams the disease was very destructive, the water being contaminated by the washing of the clothes of cholera patients.

[1] Reading-types based upon the same plan are now in the process of construction.

FURTHER DECLINATIONS OF OFFICE IN THE CONGRESS.—We are informed that Dr. James F. Hibberd, of Richmond, Ind., has declined to accept the Vice-Presidency of the Section of Physiology, that Dr. J. H. Wythe, of San Francisco, has declined the office of Councillor in the same Section, and that Dr. Henry D. Noyes, of New York, has declined the Vice-Presidency of the Section of Ophthalmology.

THE REMOVAL OF DR. L. C. LANE FROM THE VICE-PRESIDENCY OF THE CONGRESS.—In refutation of the charge made at the Chicago meeting of the New Committee, that Dr. L. C. Lane, of San Francisco, was an advocate of the New Code, the *Pacific Medical and Surgical Journal* publishes two letters which it has received, and from which we make the following extracts.

Dr. W. P. Gibbons, President of the Medical Society of the State of California, says:

"I deem it proper to state that I know of nothing, nor have I ever heard aught, either publicly or privately, that justifies this implication.

"Furthermore, after a personal acquaintance of over twenty years, and an intimate knowledge of his professional career during this time, it affords me pleasure to state a belief which I have long entertained, in common with the mass of physicians on the Pacific Coast, that his labors as a physician and a public teacher have been associated with an untarnished reputation, and that he is deservedly entitled to be placed among the foremost of those who have advanced the science of regular medicine, and aided in building up its superstructure on the western slope of the continent."

Dr. J. Grey Jewell, President of the San Francisco County Medical Society, writes:

"No man has ever been, or could be, more loyal to regular medicine and the old code of ethics than Dr. L. C. Lane. The charge to the contrary recently made against him at Chicago was a painful astonishment to me, as well as to the leading members of the medical profession here, with whom I have conversed freely on this matter."

The *Pacific Medical and Surgical Journal* makes the following comment:

"Dr. Lane is in good standing in the State Society, and the State Society with the American Medical Association, and therefore to say that he was a 'new code' man can only have been used as an excuse to prevent his reappointment. A removal such as this, for such a reason, will produce an ill feeling among the profession of California, which will only help in preventing the meeting of the Congress upon American soil being an honor to America."

HOME OPINIONS ON THE CONGRESS OUTLOOK.—The destructive work of the American Medical Association, and the reconstructive work of its new committee, do not appear to be gaining favor with the profession at large.—*Louisville Medical News*, August 15.

The outcome must be either a final refusal of the Congress to meet in this country, or a meeting which is a practical failure.—*Northwestern Lancet*, August 15.

Without doubt, the American Medical Association is the representative of the profession, and therefore the Congress convenes under its auspices; but it should be borne in mind that this latter body is an assembly of medical men, and not a convention of societies, and is not therefore bound by any code of ethics.

The profession in every country has its own rules for the guidance and government of its members, and therefore the code of the American Association cannot be taken as the criterion for the fitness of any man to occupy a seat in the Congress.—*Pacific Medical and Surgical Journal.*

A BRITISH OPINION ON THE CONGRESS DISSENSIONS.—In the United States the organization of the profession is purely democratic; there is no common link like that of our Royal Colleges; no recognized headship like that of our President of the College of Physicians, or our President of the College of Surgeons. According to the very political theory on which the State is founded, every man has as good a right to lead as any other, if he can only get that right admitted by his fellows, and for that purpose one vote is as good as another. Distinction in science and reputation abroad supply no reason to a practitioner in Texas or Colorado why he should follow a Wendell Holmes or a Weir Mitchell, in preference to a Shoemaker or a Beverly Cole. Hence a revolt of the "rump" in the United States threatens to prove a much more disastrous affair than it would be in England, and hence we especially ask our readers' sympathy for those well and widely known American practitioners, whose title to lead their profession is admitted everywhere except in the ruder and remoter States of their own country.

We have had an opportunity of seeing several letters from distinguished American practitioners, and they all concur in expressing the most bitter grief and disappointment at the pass to which their profession has been brought. In these letters we have met with scarcely one word of anger against the dissidents who have rudely torn up the first programme of the Congress. Indeed, if we may say so without impertinence, the spirit in which the "leaders" of the American profession—for we will still venture to call them so—have met the recent crisis, is one which reflects the highest possible credit upon them. We hardly know which to praise most: their patient suspension of action until the Chicago meeting had confirmed the spirit of the proceedings at New Orleans, or their swift and unanimous protest and withdrawal from the Congress when definite action was at length called for. The only hope for the Congress—the only possibility of maintaining the dignity of the profession—lay in such firm and united action on their part, and the effect of this action has been so favorable that there already appears to be a much more hopeful feeling in the States as to the prospects of a peace with honor. The organizers of the revolt are meanwhile making frantic efforts to prevent further resignations, and are even said to contemplate throwing over Dr. Shoemaker, on the score of his supposed unpopularity. But we may take it that no concessions on their part will be accepted short of unconditional surrender and full recognition of the authority and acts of the original committee. These are the essential preliminaries to the holding of any International Congress at all, and every day increases the prospect of their general acceptance. The sooner they are accepted, the better. There will then be still two

Digitized by Google

years in which to bury the hatchet, two years in which to prepare a Congress which shall "whip creation." We had all made up our minds for that, and shall be disappointed with anything less.—*The London Medical Times.*

THE NEW COMMITTEE ON THE ORGANIZATION OF THE CONGRESS AND THE ORIGINAL COMMITTEE.—The following lists are published in compliance with a number of requests which have been received for information as to the respective membership of the two committees:

The New Committee.	*The Original Committee.*
J. W. S. Gouley, New York.	Austin Flint, New York.
A. H. Wilson, South Boston.	Henry I. Bowditch, Boston.
H. F. Campbell, Augusta, Ga.	H. F. Campbell, Augusta, Ga.
E. P. Cook, Mendota, Ill.	N. S. Davis, Chicago.
J. W. Dupree, Baton Rouge.	T. G. Richardson, New Orleans.
Beverly Cole, San Francisco.	Levi C. Lane, San Francisco.
J. V. Shoemaker, Philadelphia.	Alfred Stillé, Philadelphia.
John S. Billings, U. S. A.	John S. Billings, U. S. A.
John M. Browne, U. S. N.	John M. Browne, U. S. N.
Robert Battey, Rome, Ga.	Robert Battey, Rome, Ga.
J. W. Parsons, Portsmouth, N.H.	Clarence J. Blake, Boston.
S. C. Gordon, Portland, Me.	Henry P. Bowditch, Boston.
A. Y. P. Garnett, Washington.	Samuel C. Busey, Washington.
W. C. Wile, Sandy Hook, Conn.	James R. Chadwick, Boston.
L. P. Bush, Wilmington, Del.	J. M. Da Costa, Philadelphia.
R. D. Murray, Florida.	John C. Dalton, New York.
X. C. Scott, Cleveland, Ohio.	W. W. Dawson, Cincinnati.
Ellsworth Eliot, New York.	Francis Delafield, New York.
Geo. J. Engelmann, St. Louis.	Geo. J. Engelmann, St. Louis.
N. F. Essig, Plattsburg, Mo.	Wm. A. Hardaway, St. Louis.
I. Minis Hays, Philadelphia.	I. Minis Hays, Philadelphia.
D. W. Stormont, Topeka, Kan.	D. L. Huntington, U. S. A.
D. A. Linthicum, Helena, Ark.	A. Jacobi, New York.
A. R. Smart, Hudson, Mich.	Hosmer A. Johnson, Chicago.
Christopher Johnston, Baltimore.	Christopher Johnston, Baltimore.
R. A. Kinloch, Charleston, S.C.	R. A. Kinloch, Charleston, S. C.
J. M. Taylor, Corinth, Miss.	George M. Lefferts, New York.
R. C. Moore, Omaha, Neb.	Joseph Leidy, Philadelphia.
T. F. Wood, Wilmington, N.C.	S. Weir Mitchell, Philadelphia.
G. A. Ketchum, Mobile, Ala.	Henry D. Noyes, New York.
George F. French, Minneapolis.	Thaddeus A. Reamy, Cincinnati.
William Pierson, Orange, N. J.	Thos. F. Rochester, New York.
Lewis A. Sayre, New York.	Lewis A. Sayre, New York.
F. M. Beard, Vincennes, Ind.	Jonathan Taft, Cincinnati.
J. S. Lynch, Baltimore, Md.	W. Chew Van Bibber, Baltimore.
W. E. Anthony, Providence.	Horatio C. Wood, Philadelphia.
W. H. Wathen, Louisville.	David W. Yandell, Louisville.
F. L. Sim, Memphis, Tenn.	Chairman of Com. on Finance.
Wm. McLaughlin, Texas.	R. Palmer Howard, Montreal.
Surgeon-General U. S. A.	Surgeon-General U. S. A.
Surgeon-General U. S. N.	Surgeon-General U. S. N.
Surgeon-General U.S.M. H. S.	President of Am. Med. Assoc.
W. C. Dabney, Virginia.	
E. T. Upham, West Randolph, Vt.	
G. Baird, Wheeling.	
W. Watson, Dubuque.	
N. Senn, Milwaukee.	

PRECAUTIONS ON THE BORDER LINE AGAINST SMALLPOX.—Acting Secretary Fairchild has decided to comply with a request from the Governor of Michigan for the temporary appointment of sanitary inspectors to aid the State authorities in preventing the introduction of smallpox into Michigan from Canadian ports. These inspectors will be under the direction of the Marine Hospital Service, and will be stationed at the principal points of entry, such as Detroit, Port Huron, and at the crossing of the Canada Southern Railroad. Surgeon Sawtelle, of the Marine-Hospital Service, stationed at Detroit, has been instructed to arrange the necessary details and to act in conjunction with the local authorities.

SMALLPOX IN MONTREAL.—The following report concerning the progress of the epidemic in Montreal has been received from the National Board of Health:

Number of deaths from the disease in April,	6
" " " " May,	13
" " " " June,	46
" " first two weeks in August,	45
Total,	110

Number of houses bearing placards on the 19th instant, indicating the presence of smallpox, 106.

CHOLERA CONTAGION.—The *British Medical Journal* calls attention to the fact that the next few months will see several thousand packages of fruit exported every week from the southern and western coasts of Spain—notably nuts from Barcelona, lemons from Valencia, and grapes from Almeria. These last are packed in barrels, filled up with cork-dust; and the attention of the authorities is called to the importance of this fact, in view of the great epidemic of cholera in Spain. This is the more important, inasmuch as cholera contagion is believed to be frequently conveyed by food.

PROFESSOR LEUBE, of Erlangen, has received and accepted a call to succeed Professor Gerhard at the University of Würzburg.

DRY TREATMENT OF BURNS.—Dr. Géza Dulácska recommends that burns should be dressed with soda sprinkled on cotton-wool, bandaged to the wound. The pain may be severe for a short time, but it goes off in half an hour. In an hour the effect is quite perceptible, the reddened skin having regained its natural color, and the pain being gone. In three days the epidermis comes away, leaving a healthy corium below, without pain or suppuration.—*British Medical Journal*, August 5, 1885.

LIMITS OF EXPERT TESTIMONY.—*The Therapeutic Gazette*, for April 15, quotes a case from the last volume of the *New York Law Reports* which bears on the limits of expert testimony.

A child injured in a railway accident obtained a verdict for damages on the ground of possible future consequences of the injury. The Court of Appeals held that testimony on this point was improper, and reversed the judgment. The Court held the opinion that "consequences which are contingent, speculative or merely possible, are not proper to be considered in ascertaining the damages. It is not enough that the injuries

Digitized by Google

received may develop into more serious conditions than those which are visible at the time of the injury, nor even that they are likely to so develop. To entitle a plaintiff to recover present damages for apprehended future consequences, there must be such a degree of probability of their occurring, as amounts to a reasonable certainty that they will result from the original injury."

The testimony which was thought improper by the Court was given by Dr. E. C. Spitzka, in response to a hypothetical question. He said that the points of the question proved epilepsy, while the symptoms given by the patient himself left that matter open, leaving it either as a preliminary stage of epilepsy or meningitis or traumatic dementia, the witness could not decide which. He further said that the condition of the boy was very likely to be permanent, and in response to the question as to what he meant by "very likely," he said: "I mean that the boy will always have some remnants of this injury, some reminder of it, great or small, that is certain; how much he will retain I cannot tell, but I think it very likely he will retain some." Further discussion then occurring between the counsel as to the "very likely," Dr. Spitzka said that the boy was likely to retain the greater part of the symptoms, if he did not develop worse signs, and when asked what he meant by "worse signs," said: "A patient sustaining such injuries and presenting such premonitory signs may develop traumatic insanity, or meningitis, or progressive dementia, or epilepsy with its results." This testimony the Court held to be improper, as opening the door for all possible inferences on the part of the jury, and tending to probable extravagant estimates of harm, and a new trial was therefore granted. The case is of interest, as showing the carefulness with which evidence must be given by medical experts, when future consequences of an injury are under consideration.

DRUG ADULTERATIONS IN MASSACHUSETTS. — The Massachusetts State Board of Health recently sent out some fifty orders for drugs to various apothecaries in Boston and the neighboring cities and towns, for the purpose of seeking adulterations. Among the orders was one, sent to an apothecary near Boston, for certain amounts of deodorized tincture of opium, white wine, syrup, precipitated sulphur, and zinc, all marked "U. S. P." The inspector brought back the drugs supplied in five different bottles as furnished by the apothecary. The opium was found to be just one-tenth its proper pharmacopœial strength. The white wine was simply strong alcohol. The syrup was largely contaminated with dirt. The order for precipitated sulphur the druggist declared himself unable to fill, while for zinc, two salts of that metal are said to have been furnished for the purchaser to take his choice. A prosecution is looked for.—*Boston Med. and Surg. Journal*, August 20, 1885.

TESTIMONIAL TO PROFESSOR KOCH.—On Sunday, August 2d, Professor Koch was the recipient of a handsome testimonial from the physicians who attended the "cholera course" during the past winter. It consisted of a handsome ebony case richly ornamented with silver. The lid of the case is overlaid with a silver plate, containing in relief a bust of Professor Koch and the figure of the goddess Hygeia, together with further appropriate ornamentation.

PRIORITY IN THE REMOVAL OF THE UTERINE APPENDAGES FOR THE RELIEF OF UTERINE MYOMA.—MR. LAWSON TAIT, in a valuable paper on the modern treatment of uterine myoma, which appears in the *British Medical Journal* for August 15th, says: Personal questions concerning the priority of a discovery, or priority of the introduction of new proceedings, are never very satisfactory; and I have no very great interest in this part of the present question, which has been frequently discussed, other than that I am somewhat jealous for the honor of English surgery, and do not like to see the persistent inclination on the part of some of my metropolitan brethren to give the credit of the introduction of the plan, now universally adopted, of removing the uterine appendages for the relief of pain and hemorrhage, either to Germany or to the United States, when, as a matter of fact, it was done by myself, after mature deliberation and discussion, some considerable time before it was done either by Prof. Hegar or by Dr. Battey. The details have already been published in my book, and I need only briefly refer to the fact that the first discussion and final settlement of the proposal was made in October, 1871, the operation upon that patient being performed successfully on February 11, 1872. Dr. Hegar's case was performed on July 27, 1872, with a fatal result. My second case, which was also successful, was performed on August 1, 1872; and Dr. Battey's, which was also successful, was performed, for reflex troubles, on the 17th of the same month. The discussion of the principle of the operation was given in full in my Hastings Essay on "Diseases of the Ovaries," published by the British Medical Association in 1873. So long as these facts cannot be contradicted, the whole merit of the thing, however much or little it may be, belongs to British surgery.

THE GERMAN CONGRESS OF NATURALISTS AND PHYSICIANS will hold their fifty-eighth annual meeting at Strasburg, commencing on Thursday, September 17th, and will continue for one week. Fourteen of the twenty-four sections deal with branches of medical science.

UNIVERSITY OF VIENNA.—Drs. Hofmokl, Ultzmann, and Anton Wölfler have been appointed Extraordinory Professors of Surgery, and Dr. Mauthner. Extraordinary Professor of Medical Chemistry.

THE PRIZE AWARDED TO DR. BROWN-SÉQUARD.—It is the custom of the five Academies constituting the Institute of France to award a prize of 20,000 francs every two years. The prize is successively given to a scientist, a man of letters, a philosopher, an artist, and an archæologist. Every second year one of the five Academies selects a candidate, and, with the consent of the other bodies forming the Institute, awards him the prize. This year is was the turn of the Académie des Sciences to choose the candidate. The eleven sections of this scientific body may each put forward a candidate. On the present occasion, as we announced on the 4th inst., Professor Brown-Séquard was chosen by the Section of Medicine and Surgery; and M. de

Digitized by Google

Brazza, the African explorer, to whom France is indebted for much of the territory she possesses on the Congo, was the choice of the Section of Geography and Navigation. Five other sections also nominated a candidate. So that Physiology, Geography, Mathematics, Chemistry, Botany, Physics, and Astronomy were pitted against one another for the prize—a prize, be it remembered, that such men as M. Guizot and M. Thiers were proud to obtain. At the first ballot 20 votes were given to Dr. Brown-Séquard and 15 to M. de Brazza, and the remaining 20 went amongst the other five candidates. The second ballot secured 40 votes to Dr. Brown-Séquard, his opponent merely retaining his previous votes. The Académie des Sciences having, therefore, selected Dr. Brown-Séquard for the prize, the whole Institute of France had to accept or refuse what had been done by that scientific body. The Institute ratified the choice of the scientific academy by a majority of 67 votes, the numbers being 74 and 7. It must be a source of much gratification to Dr. Brown-Séquard to find that his efforts to extend our knowledge of physiology and pathology have been so ungrudgingly appreciated by the Académie des Sciences, as well as by the whole Institute of France.—*Lancet*, July 25, 1885.

DR. MERKEL, Professor of Anatomy in the University of Königsberg, has been appointed to succeed Professor Henle in the Chair of Anatomy at Göttingen. Dr. Merkel is a son-in-law of Professor Henle.

A ROYAL PRACTITIONER OF MEDICINE. — Prince Ludwig Ferdinand, of Bavaria, son-in-law of Queen Isabella of Spain, who obtained the degree of Doctor of Medicine at Munich last year, is, according to the *British Medical Journal*, now practising at Nymphenberg, Bavaria.

PRIZE FOR A NEW EAR TRUMPET.—BARON LEON VON LEUVAL, of Nice, founded a prize of 3000 francs, on the occasion of the Third Otological Congress, for the best instrument, constructed on the principle of the microphone, for assisting the faculty of hearing for deaf people, being one that can be conveniently carried about. Those competing for this prize are to send their instruments before December 31, 1887, to one of the members of the jury, namely, Prof. Dr. E. Hagenback-Bischoff, president of the jury, at Basle; Dr. Benni, at Warsaw; Prof. Dr. E. Burckhardt-Merlan, at Basle; Dr. Gellé, at Paris; or Prof. Dr. Adam Politzer, at Vienna. Only finished instruments will be accepted, which will be tested as to the perfection of their mechanical construction, and the correct application of physical laws, but chiefly as to their powers of improving the sense of hearing. The judgment of the jury will be made known at the Fourth International Otological Congress at Brussels, in September, 1888.—*British Medical Journal*, August 8, 1885.

PROFESSOR P. VOGT, who succeeded Prof. Hueter in the Chair of Surgery at Greifswald, died suddenly recently in the forty-first year of his age.

DEATH OF PROFESSOR FEHLING.—Professor Herman von Fehling died recently at the age of seventy-two. His name is familiar to every practitioner of medicine as the originator of Fehling's Solution. The adoption of his method to determine the presence of sugar in the urine was universal, and is still recognized as one of the best means for the purpose. He was a pupil of Profs. Liebig and Dumas. His contributions to the advance of chemical science are valuable. In 1831 he received the Professorship of Chemistry at Stuttgart, and filled the Chair up to the time of his death.

NOTES AND QUERIES.

To the Editor of THE MEDICAL NEWS.

SIR: Having received inquiries from a number of your readers concerning the apparatus for the inhalation of compressed air, alluded to in a recent article in your columns, permit me to make use of the same columns to say that the apparatus was made for me by Queen & Co., of this city; that the cylinders should be made of zinc; and that the diameter of the inner cylinder should be twelve inches.

Yours respectfully,
SOLOMON SOLIS-COHEN.

1826 WALLACE STREET, August 19, 1885.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 18, 1885, TO AUGUST 24, 1885.

STEPHENSON, WM., *First Lieutenant and Assistant Surgeon.*—Granted leave of absence for one month, to take effect Sept. 1, 1885.—*Fort Niobrara, Nebraska, S. O. 97, Department of the Platte*, August 20, 1885.

BLACK, C. S., *First Lieutenant and Assistant Surgeon.*—Upon return of Troops F and L, Third Cavalry, to Fort Davis, Texas., to rejoin his proper station at Fort Clark, Texas.—*S. O. 98, Department of Texas*, August 13, 1885.

MCCAW, W. D., *First Lieutenant and Assistant Surgeon.*—Having reported back at these headquarters from detached service, ordered to rejoin his proper station, Fort Lyon, Colorado.—*S. O. 122, Department of the Missouri*, August 17, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING AUGUST 22, 1885.

M. C. DRENNAN, *Surgeon.*—To temporary duty at Annapolis, Md., as member of Board for Physical Examination of Candidates for Admission to U. S. Naval Academy.

WM. J. SIMON, *Surgeon.*—To temporary duty at Annapolis, Md., as member of Board for Physical Examination of Candidates for Admission to U. S. Naval Academy.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING AUGUST 22, 1885.

BAILHACHE, P. H., *Surgeon.*—Granted thirty days' leave of absence, August 15, 1885. Chairman of Board to examine candidates for appointment as Cadet in the Revenue Marine Service, August 19, 1885.

IRWIN, FAIRFAX, *Passed Assistant Surgeon.*—Recorder of Board, August 1, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

AMENORRHŒA.

A Clinical Lecture delivered at the Long Island College Hospital.

BY A. J. C. SKENE, M.D.,
PROFESSOR OF GYNECOLOGY TO THE LONG ISLAND COLLEGE AND POST-GRADUATE SCHOOL OF NEW YORK.
(Reported by Edward Develin, M.D.)

GENTLEMEN: To-day I shall take up the subject of amenorrhœa and discuss fully the etiology of this difficulty, illustrating the same with some cases of extreme interest and value to us.

In organic diseases, especially those of the liver, heart, lungs, or kidneys, in the advanced stages, we may look for derangements of menstruation. Those of you who have studied the pathology of these organs know that if there be an obstruction to the return circulation, from hepatic disease, for example, passive hyperæmia ensues, and if long continued tends to produce degenerative action. Hence, we find what is termed secondary degeneration of the pelvic organs arising from organic disease of the liver. We also find the same state arising from valvular lesions of the heart; the result is, of course, produced indirectly, but, nevertheless, the organic disease is the primary cause and starting point of this derangement of the menstrual function, which may be either menorrhagia or amenorrhœa; and a careful study of the lesions of the circulatory system cannot fail to show you how this comes to pass.

It is, however, not so easy to state why Bright's disease of the kidneys should produce derangements of menstruation. Amenorrhœa is naturally a consequence of hepatic or heart affections, but in renal disease the pathology is not as easy of explanation, as it is perhaps less mechanical than the former. I presume in amenorrhœa occurring from renal disease, that it is due more to malnutrition, tissue deterioration, and anæmia. The point, however, to which I specially call attention is the necessity for us to look well to the general organization in obscure cases, and seek there the causes of amenorrhœa, rather than in the pelvic organs themselves.

In support of this I will briefly relate a case that came under my observation. A lady suffering from menorrhagia called upon one of our distinguished gynecologists in New York, for consultation as to her condition. His attention was entirely directed to the pelvic organs. He used every means at his command, including frequent curetting of the uterus, but the menorrhagia still continued. One day she died very suddenly, and the post mortem revealed marked cardiac disease, this being the cause of her death. The uterus was perfectly normal, except some evidence of a passive hyperæmia, occurring as I have previously stated. Had this gentleman for a time forgotten his special department and taken a broader view of his case, he would at once have seen that it was due to cardiac disease. I mention this here in order that others may not fall into the same error. Therefore, if you do not find any well-defined local cause for the derangement of menstruation, look to the organs of nutrition.

I would now call your attention to the management of amenorrhœa in chlorotic patients. This condition, known as chlorosis, presents that peculiar form of organization in which we have a partial arrest of the development of the circulatory apparatus and sexual system.

The consequence arising from this insufficient development is that amenorrhœa is the rule, as is also anæmia. In chlorosis especially, the blood-making organs are sluggish and defective, and while the patient appears healthy, apparently, owing to the amount of adipose tissue observable in this condition, the heart action is feeble and easily gives out; they become tired easily on the least exertion. Such individuals cannot afford to menstruate, although they may do so under ordinary circumstances. But the moment you put a tax upon the system by which their vitality is used up in other channels, they become very anæmic, and amenorrhœa follows.

You will also find that these patients do not respond well to restoratives and tonics, as will any well-developed organization that is simply suffering from anæmia for the time being, because of this peculiarity of organization which I have just described. You give them iron and good nourishing diet, and they improve so slowly and fall back so often that you become almost discouraged. In these cases of chlorosis you will find the alterative tonics effect by far the most satisfactory results. Until I adopted this plan of treatment I made but slow progress in my treatment of chlorosis. You can, of course, never change the organization, or make a well-developed, ruddy, vigorous woman of such a patient; but you can regulate their digestion so that assimilation is greatly improved, and a fair condition of health maintained. In these cases you will find iodine, in the form of iodide of iron, answers well; this, however, is better in the strumous diathesis. In these cases of chlorosis we find that small doses of mercury is one of the best possible tonics. Now I know that I am taking a liberty when I mention mercury in small doses as a tonic. But we are indebted to Prof. Edward Keyes, of New York, for demonstrating that the actual number of red blood-corpuscles is increased by the administration of small doses of mercury in syphilis, and I think it has a similar effect in chlorosis. I know that if you give from one-thirtieth to one-fiftieth of a grain of the bichloride to a chlorotic patient three or four times daily, she will improve under the treatment, especially if you add the chloride of iron.

We must also remember that in the chlorotic girl the nervous system is below par, which would indicate the administration of the chloride of arsenic. Such patients are likely to be very dyspeptic, indicating a lack

Digitized by Google

of gastric juice, or its properties; hence, we administer hydrochloric acid. These remedies are contained in the mixture called "the four chlorides," viz., chloride of iron, chloride of arsenic, bichloride of mercury, and hydrochloric acid. Under this treatment it is surprising how these pale, greenish-yellow-looking girls will improve; but you must continue it for some time in order to obtain the best possible results.

Some may ask, "Are you not afraid to give one-fortieth of a grain of the bichloride of mercury for a long time?" I have given it for two months regularly, and then stopped for one or two weeks, and then again continued it for one month longer, without any bad effects whatever ensuing. I have also known it to be given for a longer period than that with most marked beneficial results.

In discussing this subject of amenorrhœa, I cannot impress upon you too strongly the recognition of this peculiar organization in those individuals known as chlorotic, because these often suffer from derangement of the menstrual function, and are more difficult to relieve than ordinary cases of amenorrhœa.

Case I.—I have here now a patient suffering from amenorrhœa, which will illustrate one or more points in regard to the relationship existing between the sexual system and the general organization when the reproductive function or reparative process is at fault. She has now reached her twenty-first year.

The question here arises, What is the cause of this amenorrhœa? The true meaning of the term, as you are aware, indicates the complete suspension of the function of menstruation. Let me say just here, that we are in the habit of taking some liberties with the term, as we sometimes say a patient is suffering from amenorrhœa when she is suffering from *scanty* menstruation. But the term means complete suppression of the menses; and in the patient before you we have this complete suppression.

She informs me that she commenced to menstruate when she was about sixteen years of age; at that time she was living in Ireland; she left her native country just six months ago. She has five sisters and three brothers, all of whom, she says, are apparently healthy. The father is alive, but the mother died of consumption, as did also other members of her family, including some aunts and uncles. The patient furthermore informs me that she has always enjoyed good health, has not had any pain, and that her menstruations were perfectly normal until one month before leaving Ireland, when they failed to appear, and since that time she has never menstruated, but has suffered with a general decline of health.

Here we have sufficient clinical history to settle one or two points. You remember I said there were certain conditions necessary to normal menstruation. First, a good general condition of the body with efficient brain and nerve power. Second, sexual organs perfect in their development and function. We find in this case that we have had all of these conditions. I know from her clinical history that she is a woman who has had a generally good organization, and also that her sexual organs have been well developed and capable of performing their natural function. She is, as you observe, a little above the average size woman, and her general appearance is good; and a more important fact is, that she began to menstruate at the time of life which is natural to that climate. This function occurred regularly, and I have no doubt lasted the average period, and, I presume, presented its natural characteristics.

There is one important point to which I wish to draw your attention, and that is that she missed one menstrual period *before* leaving Ireland; at that time she did not suffer in any way; there was no pain, there was no cough. Her friends advised her to consult a physician before she left; others again said the sea voyage would probably cause the periods again to appear. The result, however, was that she left her home without consulting a physician. Now, had she menstruated regularly up to the time of her departure, and then ceased to menstruate upon her arrival here, it would not be at all surprising, as, if a sea voyage be made close to, or during, the menstrual period, there is often observed a suspension of this function for a time, especially if the individual suffer much from seasickness. But why, you ask, should this seasickness produce this result? Because it produced a deranged innervation with a peristalsis upwards; they have not sufficient force left to carry on the natural functions in other directions. Thus it is sometimes we find strong, healthy, vigorous-looking girls come to us suffering from this suppression of menses, having recently made a sea voyage; and we cannot find any cause but this seasickness to account for their abnormal condition. These, however, in time menstruate normally; they have no disease, no anæmia, or any displacement of the organs; there is nothing wrong with them except that this function has been arrested by seasickness. It is, therefore, in such cases one of the causes of amenorrhœa.

This may have been the cause here in the case before you, but if so, why has she not menstruated since she landed? Why did she cease to menstruate before she left Ireland? Her health, I fear, was failing before she left her home to come here. You can observe that she is anæmic, the color of her face, lips, and tongue tells you this; it may be, therefore, consequent upon some trouble that began before she left home, and has increased since she came here. Her pulse is weak, thready, and small; her appetite is very poor, and she states that she can go all day without eating food, and then has no desire for any. Her breathing also is short, and she is at present troubled very much with a cough, especially at night. We may find some malcondition of the nutritive system which may account for this, and upon examination we find an abnormality at the apex of the left lung, indicating plainly that the patient is suffering from phthisis. This, together with the history we have already obtained, points to this disease as the cause of her anæmia, cough, and fever, and resulting in the suppression of menstruation. Here, then, we have a condition of the general organization which accounts for her amenorrhœa.

Of course, as physicians, we have to think that the faulty organization is not the only cause; there might be other causes at work, causes which would be physiological, and would not require the services of the gynecologist, but rather the services of the obstetrician. The only peculiarity about her case is this: The rule is that amenorrhœa appears in the advanced stage of phthisis pulmonalis; when patients are in the third stage of the disease the menses become scanty, and

Digitized by Google

finally cease altogether. But there are exceptions, and this case now before you well illustrates such a one. Where amenorrhœa occurs in the first stage of phthisis it seems to come simultaneously with the lung trouble. In this case it is evidently conservative; a patient with marked degeneration of the lungs suffers from impairment of the whole nutritive system; she cannot then afford to menstruate. The system is below par, and there is a want of the reparative process of nature which has heretofore supplied and sustained the sexual organs in their natural functions; and thus nature herself reserves all her available forces in order to supply the system with the nutritive properties necessary to carry on the power of supporting life. We find, then, owing to this diseased condition of the body, that the function of appropriating nutriment for the sustenance of life is imperfectly carried on; and the products which have undergone a tissue metamorphosis are slowly used up, owing to the non-assimilation and non-appropriation of the nutriment supplied to the body; hence, we have this gradual emaciation, followed by exhaustion, until life itself is extinguished. In these cases of phthisis we then say we are glad when the function of menstruation is abandoned by nature, as in all probabillty the patient will live the longer. It may be, and I presume it is, conservative when this function is abandoned in the early stages of the disease, or when we have that condition of the system which tends to tuberculosis.

When we have an underlying tendency to disease, and when that tendency becomes or develops into actual disease, and amenorrhœa follows, it is then a conservative force. In these cases, then, we should be constantly on our guard; for you will find the relatives of your patient oftentimes insisting that if the doctor could only restore the menstrual flow the patient would be sure to recover. And should your patient die, you will perhaps find some who will still insist that her death was owing to lack of ability upon the part of the physician to restore the menstrual function. You may talk to them of inherited tendency; they will not know and will not care, they only know that she menstruated once, and why cannot you bring around the function as it used to be? These people will torment your life out almost by their persistent obstinacy and lack of reasoning power.

Now, if in the first place, upon the cessation of menstruation, you say to the relatives that it is conservative, and is an effort upon the part of nature to reserve her forces to meet the waste of other parts of the system, that your patient will live the longer for it, and that you are glad it has occurred, they will the more readily understand you, and place full reliance in you; tell them plainly that you do not desire her to menstruate.

In this case before us I have no hope of menstruation ever again occurring; her pulmonary difficulty will increase, as she has not the means and necessaries by which she can endeavor to arrest her malady. She cannot take proper care of herself; but whatever will relieve her lung trouble will tend to restore menstruation.

The cause here is organic disease of the respiratory organs, and until that is removed we can do nothing in the way of treatment for her amenorrhœa. I insist upon this, and cannot impress it upon you too strongly, as upon this subject the laity, you will find, will have a great deal to say. Again and again have I seen them insist that the amenorrhœa was the cause of the pulmonary difficulty; they would insist upon giving the patient hot foot-baths, hot drinks of all kinds, with decoctions of herb teas innumerable, in order, as they said, to establish menstruation.

This patient I will now hand over to Dr. Cushing, who will place her under good tonic treatment, with directions as to hygiene, etc.

Case II.—This young girl is seventeen years of age, and, like our previous case, is suffering from amenorrhœa. The cause of this condition we will at once proceed to investigate. She informs me that she commenced to menstruate when she was about sixteen years of age, and continued to do so for some five months. About six months ago she came to Dr. Cushing, six weeks having elapsed since her previous menstrual period.

To digress for a moment, I might here say that we can settle one question, namely, that of development. Here is a young girl who began her menstruation at the natural time of life, and continued to do so for some time, the function for some cause having then been arrested. This has shown us clearly that the organs have been fully developed; we can, therefore, exclude the non-development of the sexual organs as a cause for this amenorrhœa.

Since she has been under the care of a physician she has menstruated three times; this makes it once in every two months, and it is now some seven weeks since menstruation occurred. We have here, then, a case of retarded or interrupted menstruation.

When she was fifteen years of age she commenced to work in a paper factory, and has continued at factory work since that time. Now here we have a patient who has a fairly good organization; she is well developed and of quite the average size for her age. Here, then, we can not only exclude non-development of the sexual organs as a cause of her amenorrhœa, but we can also exclude that of general lack of development. We must, therefore, look for some cause intercurrent to account for her present condition. As she now is, she has quite a fresh color in her cheek, but this is principally owing to the excitement and nervousness induced upon appearing before so many medical men.

We must now take into consideration that early in life this girl had to work and earn her own living, working, perhaps, in an illy ventilated room with a number of other people where the air was foul and unwholesome from the crowding together of the occupants. She has, therefore, been placed under those conditions which derange the functions of life, her nutritive system having been in all probability taxed to its utmost. We find that in classifying the human family we cannot write the history of the human species as we can of those of birds and beasts, where the history of one represents the whole of that species. If you try this method with the human family, you will fail most signally. Just consider the difference between the conditions of any of the fashionably dressed and better class of ladies in our cities, and that of this girl who spends ten hours a day amidst the dust and oil of machinery, where, if you did not look closely, you would almost think she was part of the machinery, so

Digitized by Google

automatic do they become. Compare, I say, the histories of these two classes and you will say they do not belong to the same race. So then must we seek different causes as to this condition of amenorrhœa. In the latter case we have a human being overtaxed, poorly fed, and deprived of that greatest of necessities to good health, pure air. Is it then any wonder that in such a case we should find derangement of nutrition? This girl cannot afford to menstruate regularly although originally prepared to do so; she has not nerve-force and nutritive material to spare for this purpose; she has not the blood supply, although she has the organs ready to fulfil their part. Now, her physician has been trying to build up her health, and has partially succeeded in so doing, and would no doubt have done so much more quickly had she been able to leave her work and secure proper diet and exercise.

We then find that this girl is suffering from amenorrhœa from derangement of nutrition only and not from organic disease. Between these two points you can draw the difference, and thus discern the cause most readily. This case and the previous one are both alike in symptomatology: but the troubles arise from entirely different causes; one probably incurable and the other entirely curable.

Case III.—We have here a patient eighteen years of age. She comes to us to day with the statement that she has never menstruated, and desires to know the cause and place herself under treatment, in order that this function may be brought about.

The question in this case arises, Is this amenorrhœa due to retarded development, or is it due to malnutrition? She is certainly old enough to menstruate, so we can leave that out with perfect safety in seeking for the cause of her amenorrhœa.

She states that she has been compelled to go out and do housework in order to support herself ever since she was nine years of age; she has never been strong, being also somewhat small in size, but yet she has never had any serious sickness. Her appetite has not at any time been what would be called good. She has had nine brothers and sisters, three of whom are dead, she herself being next the youngest. Both parents are dead, but she cannot give the cause of death in either case.

A question here arises whether this retarded puberty be due to transmitted disease or the abnormal conditions of life by which she has been surrounded. Her general development indicates that she is big enough to menstruate, but there is an arrest of that special development which occurs at puberty, the breasts and sexual organs being undeveloped. Her parents, we have heard, died before she was old enough to take cognizance of the fact, and there have also occurred three other deaths in the family. It would, therefore, be fair to presume that her general organization as transmitted is not perfect. Her life and pursuits also have been hard from infancy up, which condition would also tend to retard her sexual development, the vital forces being used up in her daily avocations.

Here, then, we have a combination of conditions, either of which would tend to retard this development. The patient is very anæmic, as can be plainly seen, this condition probably being induced by her surroundings, and this, acting upon an organization which from the outset was illy qualified to carry on its natural functions, fully accounts for her amenorrhœa.

This girl then simply fails to menstruate because of this retarded development of the sexual organs. She has not had the vital energy sufficient to complete the secondary development of her sexual organs and at the same time attend to her daily labors.

Under these circumstances what shall we do? I presume that the sexual organs are not absent: we will, therefore, simply endeavor to change her conditions of life; let her do less work and do more for herself in the way of securing good nourishing diet and restorative tonics, and I have no doubt that if we can do this, her secondary development will follow, and that she will menstruate normally.

Now compare this treatment with that in vogue some years ago. The opinion then held by the laity and the profession as well, was that this amenorrhœa was the cause of the anæmia and ill-health of the patient. The treatment was then directed to establish or restore the menstrual function. This kind of practice was based upon the belief that, if this would be effected, a better condition of health would be the result, hence emmenagogues were used. We now know that the amenorrhœa is not the cause, but rather the effect of this anæmia and low condition of vitality. Instead, therefore, of dosing our patients with medicines to stimulate the pelvic organs, using hot foot-baths, etc., we now reverse the order of things and take the amenorrhœa as the consequence of ill-heath and leave the sexual system alone; knowing that we can only reach them through the nutritive system, and if we can succeed in building up the general health of the patient, the development of the sexual system will follow, and menstruation will appear in due time.

Case IV.—This patient that I now present to you came to me two years ago. She was then seventeen years of age and suffering from amenorrhœa. She was then, as now, undersized for her age; but since that time she has greatly improved, but as you can plainly observe, she is the subject of an arrest of general development.

Although seventeen years of age when she came to me, she had never menstruated and presented the appearance of a girl twelve years of age. She was born of perfectly healthy parents, but at the time that I saw her she was suffering from an acute disease of the liver. I am perfectly well acquainted with this child's history, as I have attended the family and know that there is transmitted disease in the case. This well illustrates the subject I have heretofore alluded to: I refer to organic disease being a cause of amenorrhœa; but in this case we have a chlorotic condition and retardation of development of the sexual organs, acting in conjunction with some disease of the abdominal viscera to bring about the derangement or menstruation. She has, of course, also as a natural result of the disease and chlorosis, become somewhat anæmic Now, although she is not at the present time a very robust or healthy looking girl, she has improved in her general condition and her anæmia is not so marked. She has also menstruated, but not perfectly; menstruation being irregular and failing in its usual characteristics. It is, however, a step in the right direction, and, in all proba-

Digitized by Google

bility, this function may be fully established if the treatment be continued.

At the time she first presented herself it was a question as to whether there might not be some transmitted specific taint; and because of that, it was suggested that specific treatment be adopted; but the family history and general appearance of the girl, overruled such an inference. She was therefore placed upon the mixture of the chlorides before mentioned, and I am pleased to show you the efficiency of the treatment. There was, however, in addition, quinine and iron administered, the vicinity in which she resided being somewhat of a malarial district, and she had previously suffered from this miasmatic affection. We will continue to give her the citrate of iron and quinine and the mixture of chlorides, alternating them.

Case V.—This patient is 40 years of age, and, like our previous case, is suffering from amenorrhœa. This one, however, is more on the descending line of life, while the other was but at the commencement. In all probability, therefore, we shall find that her amenorrhœa arises from a different cause. She informs me that she has been married for twenty years, and that she has borne three children. She further states that her menstruations were regular until eight months ago, when she contracted a severe cold from exposure and wetting of the feet; and, to make it still more severe, her menstrual flow had at that time just commenced, and was immediately checked owing to this cold and exposure. She complains, also, in addition to her amenorrhœa, of a severe cough, keeping her awake at night; shortness of breath, so much so that she can hardly walk up stairs; she has profuse expectoration; and her appetite is very poor; in fact, she is extremely weak and anæmic. We here see also a sign of what at one time was considered pathognomonic of phthisis. I allude to these curved finger-nails, which give a club-shape to them. This is stated even now by some to be a sign of tuberculosis, but I have very good reasons for believing that it may occur in other diseases as well as in tuberculosis; in fact, I am well satisfied in my own mind upon this point. Now, is this amenorrhœa due to organic disease of her nutritive system, or is it simply a premature menopause? It is certainly not uncommon for menstruation to cease at forty, for this function varies in different individuals. I have seen a case in which the menopause occurred at twenty-eight years of age, and cases have been reported at twenty-five years of age. On the other hand, I have met women in whom menstruation had been maintained beyond the fiftieth year; and in these various ages the individual has maintained a fair degree of health. Now, if this amenorrhœa in this patient is owing to a premature menopause, we need not be anxious about her, as it is then physiological. But we cannot rest here, as she has other symptoms which must be detrimental to health; I allude to her pulmonary difficulty. The doctor who has examined her has not been able to satisfy himself that she has tubercle of the lungs, although feeling convinced that a tendency to tuberculosis is the cause of her amenorrhœa; and, taken with her history, it appears to me more likely to be the cause than her age. As a rule, amenorrhœa always occurs in the advanced stage of phthisis, but it may occur in some at the outset or incipient stage of the disease, as in our first case. You will find in some cases that your patient will have amenorrhœa before she manifests any well-defined lung trouble; you will almost always find some evidence of commencing tuberculosis, but it may not be marked. Now why that is, I do not know: but I know it to be a fact that this suppression of the menses occasionally occurs in the early stages of pulmonary difficulty. Those having a well-marked tubercular diathesis are most liable to early suppression of the menses.

This is practical and important to know, for you will have patients brought to you suffering from amenorrhœa with no marked history of lung trouble; but, if you are careful in your examination, and secure a thorough history of the case, and go back a few years to her ancestors, you may perhaps find some trace of tuberculosis, and which has in all probability been transmitted, though the symptoms and signs be but illy defined in your patient. I remember a case very well which will illustrate this: A lady came to me one day, bringing her little girl with her to be treated for some throat affection. The following day she also brought an elder daughter, aged between 15 and 16. She drew my attention to her, saying that the girl was feeling quite well, but she did not know why she should have discontinued menstruation, and had begun to feel a little anxious about it; "but," said she, "I thought it might be because she was growing so fast, and that she would again menstruate in time." The mother, however, felt anxious about her, and desired my opinion. On examination, the girl to any would seem to be in good health; she certainly had all the general appearances of health; but there were some points that, to my mind, indicated a tubercular diathesis; and from her history I ascertained that such difficulty had been in the family. I candidly told the mother my opinion, expressing it that the girl would never menstruate. This amused her very much, as to her it seemed absurd. I then told her I did not think the girl would live until she was eighteen years old. I had, by a very careful examination, discovered a very small tubercular deposit at the apex of the left lung, but the patient had no cough. Taking this deposit in the lung, together with the amenorrhœa, I felt that the chances of life were very poor, indeed. I was fully justified in expressing my opinion, as I have just stated, in order that the mother might be fully aware of the serious nature of her daughter's malady. I was not consulted again by that family for some time after, when one day the mother called at my office and asked me whether I would not change my opinion regarding her daughter's case, although up to that time she had not menstruated. The mother then left, feeling somewhat indignant at what she thought an unfounded diagnosis, causing her needless alarm and anxiety. I then lost sight of her for some time, until one day she came to my office with the girl whom she had first brought to me. She then informed me that her elder daughter had died just after her seventeenth birthday. Such instances coming before us should, then, make us the more careful in searching for the causes of this amenorrhœa.

In the present case we will therefore direct our attention to the lung trouble, and leave the sexual organs alone. If this difficulty of the lungs can be overcome, I am well satisfied that menstruation will again become established.

EXTRACT OF MALT.

BY WILLIAM L. DUDLEY, M.D.,
PROFESSOR OF CHEMISTRY AND TOXICOLOGY IN THE MIAMI MEDICAL COLLEGE, CINCINNATI, O.

THE name "Extract of Malt," as applied to a pharmaceutical preparation found in the market, today, means nothing. I do not wish to insinuate that these preparations are not *extracts* of malt, for, I doubt not, they are in one sense; but as medicines, many of them are valueless, and others fall far short in the requirements necessary for that article. Many of them doubtless are made simply to sell; others to give a palatable flavor to medicines of disagreeable taste—and indeed if they are intended for any other purpose, they are certainly dismal failures, as their medicinal value is about equal to that of ordinary molasses; while the extract as prepared by other manufacturers is of excellent quality, and fulfils all the requirements.

Extract of malt is being quite generally prescribed at present by physicians; the primary object being to assist digestion, and as the medical profession, and the public generally are being imposed upon by the manufacturers of the many valueless preparations bearing this name, I propose to describe in this paper the nature, action, methods of preparation, and properties of a good extract, and also give the results of some comparative tests made with the most prominent brands which are in the market.

Extract of malt is, (or should be, as the name implies) prepared from malt or germinated barley, and it depends for its action on a soluble ferment, called *diastase*. This body has the property of converting starch into dextrine and malt sugar. Diastase does not exist in all parts of the germinated grain, being often absent in the radicles, and generally most abundant near the plumule. It exists in the tubercles of the potato near the point of their insertion, but not in the roots or the shoots. It has also been found in the buds of Ailanthus glandulosa. Neither potatoes nor cereals contain diastase before germination. During germination the diastase is formed; its function being to convert the starch into a soluble form so as to admit of assimilation by the plant, and finally to convert it into dextrine and maltose (malt sugar). In the preparation of malt the growth of the sprout is interrupted by heating in a suitable furnace or kiln. It was noticed by Vauquelin in 1811 that starch, on being heated, was converted into a substance resembling gum arabic; and Kirchhoff, a little later, showed that by boiling starch with dilute sulphuric acid, a crystallizable sugar was formed; and very soon after, Vogel found that in the latter reaction, a gum-like body was also produced. In 1814 Kirchhoff showed that the gluten contained in wheat and other grain has the power of effecting a similar change on starch, and that malted grain is most active.

Payen and Persoz were the first to isolate the active principle of malt in 1833, and to this they gave the name of *diastase*, as they believed the action of this body to be a simple separation of starch from the granule. Some time before this the starch gum had been examined by Biot and Persoz, who gave it the name of *dextrine*, from its dextro-rotary power, supposing it to be the intermediate formed in the conversion of starch into sugar. In 1860, Musculus proved this view to be incorrect, and he showed that dextrine and sugar were formed at the same time. This fact was disputed until O'Sullivan proved the truth of Musculus's view, and also showed that the sugar which is first produced from starch, is not dextrose, as had been believed, but maltose.

In addition to diastase, two other ferments are found in plants,—emulsin and myrosin. The proportion of diastase in malt does not exceed 0.002 to 0.003 per cent.

Diastase is a white, amorphous, nitrogenous substance; insoluble in absolute alcohol, soluble in water and in weak alcohol. Its aqueous solution has no decided taste, and is neutral to test paper. Placed in contact with starch at 70° C., it quickly converts that substance by hydration into dextrine and maltose. According to Payen and Persoz, one part of diastase is sufficient to liquefy and convert into sugar 2000 parts of starch; while Strecker says one part of diastase will convert 100,000 parts of starch. Observers should bear in mind in making these quantitative tests that diastase prepared by alcoholic precipitation is a complex mixture into which the really active substance enters, perhaps, only in small proportion; also, that the presence of a certain quantity of sugar interferes with the transformation of dextrine, and in order to allow the action to resume it is only necessary to dilute with water, or remove the sugar by causing it to undergo alcoholic fermentation by means of yeast.

The aqueous solution of diastase readily decomposes, turning acid, and losing its power to convert starch; but if the solution contains a small quantity of alcohol it will keep indefinitely. Dry diastase is also likely to undergo slow decomposition. On boiling it with water the decomposition is instantaneous. Bouchardat says, that the action of diastase on starch is completely prevented by nitric, sulphuric, phosphoric, hydrochloric, oxalic, tartaric, or citric acid; also by caustic potash, soda or lime, sulphate and acetate of copper, mercuric chloride, nitrate of silver, alum, and ferric sulphate; also, that it is retarded more or less by formic acid, arsenious acid, magnesium, ammonium, and alkaline carbonates; slightly, also, by acetic acid, hydrocyanic acid, strychnia, quinia, morphia, and their salts. He finds no retarding influence exerted by essential oils, creasote, alcohol, and ether.

These statements of Bouchardat are of comparatively little value, as the influence of the above-named substances on the action of diastase depends, altogether, upon the proportion; as, for instance, it has been shown that a small quantity of hydrochloric acid greatly augments the action of diastase, while a larger quantity arrests it. The same may also be said of acetic and lactic acids.

The most satisfactory method for the extraction of diastase, appears to be that of Musculus, which is a modification of the process of Payen and Persoz. It is as follows: Take one part of germinated barley,

Digitized by Google

and after pulverizing, add it to two parts of water at 25° or 30° C. After an hour's maceration press out the liquid, and add an equal volume of alcohol at 80° C. After filtering to remove the rather voluminous precipitate, which is rejected, again add an equal volume of alcohol to the filtered liquid. Collect the very slight precipitate which is then formed, on a filter, and dry it on the filter at a very gentle heat. A diastase paper, which is very active, is obtained in this manner, and may be indefinitely kept without change.

It has been proved by more recent investigation that the chemical reaction of diastase on starch is more complicated than was formerly supposed; but if we regard only the original and final terms, we are apt to arrive at the conclusion that starch under the influence of diastase combines with itself the elements of water, and is converted into glucose; thus

$$\underset{\text{Amylaceous matter.}}{C_6H_{10}O_5} + \underset{\text{Water.}}{H_2O} = \underset{\text{Glucose.}}{C_6H_{12}O_6};$$

but this is not the case. According to O'Sullivan, the following equation represents the reaction when an infusion of malt has acted on starch-paste for from 5 to 10 minutes at 63° C.:

$$\underset{\text{Starch.}}{C_{18}H_{30}O_{15}} + \underset{\text{Water.}}{H_2O} = \underset{\text{Maltose.}}{C_{12}H_{22}O_{11}} + \underset{\text{Dextrine.}}{C_6H_{10}O_5}.$$

The presence of maltose is antagonistic to the action of diastase, and, according to Payen, the action of diastase continues until 51 per cent. of the starch is converted into a mixture of maltose and dextrine, and there it stops until the maltose has been removed. It has been shown by several investigators that on adding diastase to starch-paste heated to 70° C. that the reaction by means of iodine disappears as soon as the saccharification has affected a quarter of the starch; but the action of the diastase will continue, as has been stated, until one-half of the starch has been converted. Thus it will be seen that the iodine reaction fails as soon as a quantity of maltose equivalent to a quarter of the starch has been formed; and therefore this agent as ordinarly applied to determine the amount of diastastic action is only of value in comparative tests. The disappearance of the blue color in the iodine test when the starch is only partially converted, may possibly be accounted for by the development of complementary colors; the iodine with starch giving a blue color, and with dextrine a red, together with some yellow, which is always present.

If during the reaction the maltose is removed by alcoholic fermentation, the action of the diastase will continue, and finally all of the dextrine, as well as the starch, will be converted into maltose.

The activity of diastase depends greatly upon the temperature at which it is allowed to react upon starch. At about 65° C. it seems to be most active, and at about 95° C. it is entirely destroyed. It is held by some that diastase shows slight signs of activity even at 0° C. The proportion of maltose to dextrine formed depends much upon the temperature, and length of time the reaction is allowed to continue—according to O'Sullivan, at 63° C., and from 5 to 10 minutes reaction, the equation is as follows:

$$\underset{\text{Starch.}}{C_{18}H_{30}O_{15}} + \underset{\text{Water.}}{H_2O} = \underset{\text{Maltose.}}{C_{12}H_{22}O_{11}} + \underset{\text{Dextrine.}}{C_6H_{10}O_5};$$

or one molecule each of maltose and dextrine are formed; while at a temperature between 64° and 70° C., the following change occurs provided the mixture be quickly cooled after complete fluidity:

$$\underset{\text{Starch.}}{2C_{18}H_{30}O_{15}} + \underset{\text{Water.}}{H_2O} = \underset{\text{Maltose}}{C_{12}H_{22}O_{11}} + \underset{\text{Dextrine.}}{4C_6H_{10}O_5};$$

or one molecule of maltose to four molecules of dextrine. At temperatures near 95° C. he finds the decomposition to occur as follows:

$$\underset{\text{Starch.}}{4C_{18}H_{30}O_{15}} + \underset{\text{Water.}}{H_2O} = \underset{\text{Maltose.}}{C_{12}H_{22}O_{11}} + \underset{\text{Dextrine.}}{10C_6H_{10}O_5};$$

or one molecule of maltose to ten molecules of dextrine. The dextrine formed in each case will, on long-continued contact with diastase, finally be converted into maltose; but, as before stated, this action will be much more rapid if the maltose be removed by fermentation, or the solution be diluted.

Märker seems to have arrived at different conclusions regarding the nature of these changes, and has found that more maltose and less dextrine were produced at lower temperatures than at higher ones. By the use of yeast with diastase the whole of the starch is converted into maltose which in turn is split up into alcohol and carbonic acid.

In order to test the comparative value of the extracts of malt of the most prominent manufacture found in the market, I have made some tests on samples taken by myself from the shelves of retail drug stores, and I submit the following tabulated results:

NAME.	COLOR.	ODOR.	CONSISTENCY.	TIME FOR CONVERSION.
Forbes's Liquor Diastase	Light brownish-yellow	Malt	Mobile liquid	39 minutes.
Trommer's Extract of Malt	Dark reddish-yellow	Malt	Viscid liquid	60 minutes.
W. S. Merrell Chemical Co's Extract of Malt	Light brown	Malt-sweet	Viscid liquid	85 minutes.
Keasby & Mattison's Fluid Extract of Malt .	Brownish-red	Molasses	Viscid liquid	Incomplete conversion in 3 hours.
Maltine	Reddish-yellow	Malt	Viscid liquid	Apparently no action in 3 hours.
Hoff's Extract of Malt	Yellowish-red	Malt liquor	Mobile liquid	Apparently no action in 3 hours.
Liebig's Extract of Malt	Reddish-brown	Malt liquor	Mobile liquid	Apparently no action in 3 hours.
Shaker Extract of Malt	Brownish-red	Aromatic	Mobile liquid	Apparently no action in 3 hours.

Digitized by Google

The starch paste used was prepared by boiling thoroughly 60 grains of starch with 6 ounces of water, and allowing the mass to cool. The table shows the average of twenty assays with reference to the time required for the conversion of four parts of starch to one part of extract of 65° C. (150° F.).

The iodine solution used in testing the progress of the conversion of the starch, was made as follows:

Iodine	8 grains.
Potassium iodide . . .	16 "
Water	1 ounce.

Six drops of this mixture were diluted with two ounces of water for a working solution.

In testing the comparative convertive power of extracts of malt, a given quantity of each extract should be diluted with its own bulk of tepid water, and added to equal quantities of starch solution (prepared as above) at a temperature of 65° C (150° F.), and the mixture thoroughly stirred, and finally covered with a watch glass to prevent evaporation. The temperature is to be maintained at 65° C., and from time to time a drop of each mixture should be removed and tested with the iodine solution on a porcelain plate or watch glass, or in a small vial. The iodine solution with the starch will produce a deep blue color; but as the conversion of the starch progresses the color produced will vary, becoming purple, lilac, wine-red, and finally nearly colorless, which will complete the action.

It is essential that several precautions should be observed in performing these tests:

1. The iodine solution should not be stronger than that given in the above formula.

2. In comparative examinations of malt extracts, the whole amount of starch required should be gelatinized at one time, and the same should be used for all the samples. The starch liquid should be thin, and free from lumps.

3. An aqueous solution of iodide should be used, and should be freshly made. The presence of alcohol in considerable quantity will destroy the delicacy of the reaction with starch.

4. Samples of the mixture of extract and starch liquid undergoing conversion should be allowed to cool slightly before testing.

5. The mixture should be thoroughly stirred immediately after the addition of the extract.

6. Variation in temperature during conversion is to be avoided.

It will be noticed in the above table that the Forbes liquor diastase gave the best results, and was followed by Trommer's extract, after which came the W. S. Merrel & Co.'s malt. The remaining five extracts showing practically no diastastic properties, and, as far as their value in this direction is concerned, in two cases as much beer, and in the others an equal amount of molasses, would be of almost if not quite as much benefit to the consumer.

Some pharmacists appear to be ignorant of the requisites of extract of malt, and merely consider it an agreeable medium for the administration of repulsive medicines. Considering the methods which are recommended for its preparation, it is impossible to obtain anything but a thick molasses-like mass, with the diastase almost if not completely destroyed. The following is quoted from one of the late dispensatories:

"One part of ground barley is macerated for three hours with its own weight of water; 4 parts of water are then added, and the whole digested for an hour at 65° C., heated to the boiling point, and at once expressed and strained. The clear liquid is rapidly evaporated to the consistence of a thick extract."

By this it will be seen that most of the diastase will be used up in converting the starchy bodies present during the one hour digestion at 64° C., and the remainder will be destroyed by the subsequent boiling.

The latest editions of the dispensatories give the method recommended in the new U.S. Pharmacopœia, which is as follows:

"Malt in coarse powder, not finer than No. 12, 100 parts; water, a sufficient quantity. Upon the powder, contained in a suitable vessel, pour 100 parts of water, and macerate for six hours. Then add 400 parts of water, heated to 30° C., and digest for one hour at a temperature not exceeding 55° C.; strain the mixture with strong expression. Finally, by means of a water bath, or vacuum apparatus, at a temperature not exceeding 55° C., evaporate the strained liquid rapidly to the consistence of thick honey."

This method is a vast improvement over the old one, but still much of the diastase will be used up during the digestion at 55° C., and also during the evaporation, and the product will be an insipid mass possessing little diastatic activity. The aim seems to be to obtain an extract in the form of a thick sticky mass, while a thin liquid is much more palatable and more desirable in every way. Therefore why this long, tedious, and destructive evaporation! Is it simply to make it "keep?" If so, let a different method of preservation be adopted.

The method patented by Forbes in 1883 removes these difficulties and gives a product which fulfils all the requirements. It is as follows: Percolate or macerate (with subsequent expression) the malt, ground to coarse powder, with a mixture of one part alcohol and three parts water at about 37½° C. (100° F.), evaporate (below 100° F.) or dilute to the required strength, The extract prepared in this way is practically free from starch and other impurities.

If we examine the animal organism, we find several ferments which are analogous to diastase, and by some investigators they are considered identical. Diastastic reactions play an important part in the animal economy, and especially in the digestion of starchy food. In the saliva we have ptyalin; in the pancreatic juice there exists an analogous fermentive principle in such quantity as to cause that secretion to act infinitely more rapidly on starch than saliva; in fact, its action is almost instantaneous. In the liver we also find a similar, if not identical ferment, which, in conjunction with the blood, converts the glycogen (animal starch) into sugar. The chemical phenomena of nutrition in vegetables and animals furnish a striking parallel, as shown by M. C. Bernard, who says:

"The ferment appears in seeds from the commencement of germination; this takes place in the potato in

Digitized by Google

spring; then the fermentiferous agent shows itself in the tubercle, as it did in the germinated barley. It liquefies the starch and puts it into a condition to be distributed over the parts where it may minister to the nutrition; that is to say, to the development of the life of the plant. In most animals the phase of the production of glycogen, and that of its fermentation, are not so distinct as plants. The two phenomena are often continuous and simultaneous. An exception must, however, be made with respect to the earliest periods of life, especially in those animals which undergo metamorphosis. For example, if we consider the larva of the common fly, musca lucelia, the gentle—if we call it by its common name—we find that it contains an enormous quantity of starch. It is truly a bag full of glycogen. At this time we find nothing else but glycogen, and not even a trace of sugar. The reason for this is that the glucose ferment does not yet exist. But soon the chrysalis will succeed to the larva, and then in the new phase of existence, during which the perfect animal is in formation, the reserve glycogen must be utilized, the ferment appears, and the starch is liquefied."

"Something analogous to this is seen in beings of a higher order—for example, among the mammalia at that period of embryonic life when the nutrition is hastened, and the plastic and formative activity attains its highest degree. The glycogen matter is deposited at various points of the fœtus and of its envelopes, is set in motion, dissolved, and transformed into sugar."

"The digestion of starches consists in their transformation into soluble and assimilable substances, soluble in order to be able to circulate from one part of the organism to another. Digestion is, therefore, the prologue of the act of nutrition. Whenever these starchy matters are to nourish an organism we shall find this previous preparation. But all organisms in the vegetable, as well as in the animal kingdom, employ starchy substances as food; all, therefore, digest these substances in the strict sense of the word."

It has been proved by the experiments of Cl. Bernard, Magendie, Schiff, and Hensen, that in living blood there exists a ferment capable of converting starch and glycogen into sugar. This ferment is even found in the blood of frogs in spring and summer, when, if dextrine be injected into their veins, it passes in the form of sugar with the urine; in winter it is not present, for the dextrine then passes with the urine unaltered.

Thus it is seen that diastase plays an important part in digestion by transforming the starches into soluble substances which are readily assimilated; and there seems to be no reason why a pharmaceutical preparation containing diastase, if properly prepared, would not be a medicine of great value; but it is to be regretted that many of the preparations on the market at present are of little or no value.

DISINFECTANTS.

PRELIMINARY REPORTS OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

XVI.

NOTES.

BY THE CHAIRMAN OF THE COMMITTEE.

My attention has just been called to an advertisement of "Withers's Antizymotic Solution," in which it is stated that it is endorsed as the best by George M. Sternberg, M.D., Surgeon U. S. A.

I have never authorized the use of my name in connection with this or any other proprietary disinfectant. The only reference I have ever made to "Withers's Antizymotic Solution" is in the report on "Commercial Disinfectants," No. 2, published in THE MEDICAL NEWS of June 13th, where this has the *third* place in a list of fourteen commercial disinfectants, tested under my direction by Dr. Abbott. The remark is made, "contains mercuric chloride." As a simple solution of mercuric chloride of 1 : 500 would be quite as efficient as 4 per cent. solution of this disinfectant, the extravagant claims made for it are without foundation. The assertion, that it is endorsed by me "as the best," is untrue.

Labarraque's Solution.—I have received the following letter from a well-known and reputable firm of manufacturing chemists:

"In THE MEDICAL NEWS (Philadelphia), for June 13th, we find a continuation of the Preliminary Report of the Committee on Disinfectants, including a report on the relative percentage of available chlorine, in samples of different manufacturers of Labarraque's Solution. As you are doubtless aware, Labarraque's Solution is a very unstable preparation; and, although made with every possible care, will surely deteriorate by age. With such an article it is manifestly unfair to institute comparisons between different makers without regard to the freshness, or otherwise, of the samples. To the unthinking reader the bald statement that one preparation contains 3.8 per cent., and another only 0.013, is calculated to convey the impression that the preparation which contained so small a percentage has been improperly made (while really when fresh its percentage might have been greater than the highest named); and such an impression would naturally create a prejudice against the manufacturer, and, unfortunately, not be limited to the particular article mentioned."

I recognize the fact that the unthinking reader might make an inference unfair to the manufacturer from the perusal of a "bald statement," such as is published in the table on page 659 of THE NEWS. I regret this, and will in future gladly give the date of manufacture, if the manufacturers will stamp it upon the bottle. As I propose to obtain new samples from time to time, and to publish the results of tests as to available chlorine, it may happen that the aggrieved manufacturers in this instance will come out at the head of the list the next time. But these tests are made especially in the interests of the public, which, from my point of view, are superior to those of the manufacturers, and it is evident that great harm might result from reliance upon the disinfecting power of a liquid labelled "Labarraque's Solution," which contained only 0.013 per cent. of available chlorine. The fact that it was of full strength when first manufactured, does not add to its value as a disinfectant for the excreta of a patient with cholera or typhoid fever. If the manufacturers will stamp the date of manufacture upon the label attached to each bottle, I will publish it, in future, in connection with the result of the tests to determine available chlorine present in the solution.

Disinfecting and Antiseptic Powder.—The powder under this name, for which a formula was given in

Digitized by Google

the Preliminary Report, No. IX. (THE MEDICAL NEWS of April 18th, p. 425), was withdrawn in a letter published in THE NEWS of May 2d.

The writer was responsible for this powder, and withdrew it because of the fact that mercuric chloride is decomposed by the hypochlorites in the presence of moisture. In the powder, made as directed, this reaction does not occur, and the keeping properties of the powder are all that could be desired. But when water is added to it the reaction occurs, and the yellow oxide of mercury is precipitated. This fact having been brought to my attention I hastened to withdraw my recommendation of the powder, although I had been much pleased with it in practical tests upon feces. Since my return from Europe I have made some additional experiments, which show that, notwithstanding the destruction of the bichloride, the powder is an excellent disinfectant and antiseptic. A sample which I have recently examined contained 2.6 per cent. of available chlorine after the precipitation of the yellow oxide by the addition of water. This same sample, after standing in an open box in the laboratory for about three weeks, still contained 1.5 per cent. of available chlorine at the bottom of the box, and 1 per cent. at the surface of the powder, which had been exposed to the air during this time. I have demonstrated, by recent experiment, that mercuric oxide is a valuable antiseptic. In the proportion of 1 : 2000 it retards the development of microörganisms in beef-tea inoculated with two or three drops of broken-down stock; and in the proportion of 1 : 1000 it entirely prevented development for a week, the duration of the experiment, while in the comparative test the beef-tea broke down in less than twenty-four hours. Nevertheless, I do not endorse the formula which I first recommended, for the reason that mercuric oxide has an antiseptic power inferior to that of the bichloride, and it is a waste of material to use the bichloride of mercury in the same formula with the hypochlorites. I would, therefore, recommend that the powder be made without the addition of mercuric chloride.

My object is to dilute the chloride of lime so that it may be used more economically, *especially upon the surface of fecal matter in privy vaults*. Such a powder is especially needed in country places, where the old-fashioned, open privy vaults are in use, and in garrisons and military encampments.

Chloride of lime, as received from the manufacturers, is more or less lumpy, and cannot be readily scattered about in a uniform manner. It is also much stronger in chlorine than is necessary. I have, therefore, endeavored to find an inert substance suitable for diluting it.

Plaster of Paris has the advantage of retaining the chlorine better than anything else I have tried, and makes a powder which can be readily scattered about in a thin layer. Its property of setting with water is no objection to its use in privy vaults, cesspools, etc., but would be an objection to its use in chamber vessels, the contents of which were to be thrown into water closets.

To test the keeping properties of a mixture of chloride of lime and sulphate of lime, mixed together in equal quantities, by weight, I exposed a layer having a thickness of about one and a half inches in a shallow vessel, and, for comparison, a mixture of equal parts of chloride of lime and sand in a similar vessel. At the outset of the experiment the available chlorine in each specimen was found, by Dr. Abbott, to be 15 per cent. At the end of a week the mixture with plaster contained 12.9 per cent. of available chlorine, and the mixture with sand 6.8 per cent. At the same time two fruit jars were filled about one-third full with the two mixtures, and the metal covers were screwed on. In these closed jars the mixture with sulphate of lime contained 13.5 per cent. of available chlorine at the end of two weeks, and the mixture with sand 11.8 per cent.

A CASE OF MELANO-SARCOMA.

BY W. A. ROTHACKER, M.D. AND J. A. THOMPSON, M.D., OF CINCINNATI, OHIO.

CHARLES W., an American, aged 56 years, was admitted to the Cincinnati Hospital for the first time Nov. 20, 1882. He is a carpenter by trade, of good physique, and excellent habits. There is a family history of tuberculosis in some distant relatives but no other hereditary taint. Two years before admission he noticed what he calls a blood cyst on his back about the level of the lower angle of the scapula and one-half inch to the right of the spinal column. He attributes its formation to a knot tied in his suspenders which irritated the skin at the point of contact. This cyst was opened by a friend with a needle and bled profusely. Since that time it has been growing slowly, and is now the size of a goose egg. It is globular in shape, its attachment to the body being its smallest part. It is bluish-black in color. No pulsation can be felt. Four inches below this tumor is another small bluish-looking growth under the skin.

December 3.—Both tumors were removed by Dr. D. S. Young by oval incisions, and the edges of the wounds approximated by sutures.

7th.—There is extensive inflammation about the wounds. The sutures were removed and the wounds dressed with lint and vaseline, and quinine given internally.

10th.—The wound is discharging freely and granulations are forming. Only the upper two sutures have united.

21st.—The wound is healing rapidly by granulation, and, at the patient's own request, he was discharged to spend Christmas with his family.

To Dr. L. A. Nippert, of Minneapolis, Minn., at the time a surgical interne in the Cincinnati Hospital, we are indebted for the preceding notes. No microscopic examination of the tumors (which were believed to be nævi) was made at this time.

He was readmitted to the hospital August 29, 1883, with tumors varying in size from that of a pea to that of a hen's egg, covering all parts of the body, the feet alone excepted.

These tumors seem to take their origin from the subcutaneous connective tissue; and where the skin is not involved in the growth, there is no visible discoloration. But where the skin is involved in the

Digitized by Google

morbid growth, it is of a bluish-black color. The patient states that a tumor appeared on his back directly above the site of the larger growth, removed at his previous visit to the hospital, before the operation wound had healed, but it did not prevent the perfect closing of the wound. The cicatrix has never ulcerated, been painful, nor given trouble in any way.

He did not notice any other growths until about six months after the operation, when one appeared over the anterior edge of the right sterno-mastoid muscle on a level with the angle of the jaw. This tumor at present is multiple and about the size of a hen's egg. Discovering it, he examined his body, and found the tumors, as yet small in size, all over it. At the present time (August 29, 1883) there are visible over his body five hundred and sixty-one tumors.

Three hundred and twenty-seven are not visibly pigmented, and two hundred and thirty-four show marked discoloration. By passing the hand over the skin where it appears sound and healthy other small tumors can be felt in the subcutaneous connective tissue, apparently about the size of shot. Three of the larger tumors have ulcerated, as the result of some local applications made by a firm of advertising quacks, and are now covered by scabs.

The patient states that about eight weeks ago his testicles began to swell rapidly, and continued to increase in size until about two weeks ago, when the swelling partially subsided. The scrotum is now about the size of two fists, bluish-black in color, and firmly adherent to the testicles. The left testicle is much more enlarged than the right. The only thing abnormal found on physical examination was a systolic murmur, heard at the apex beat of the heart and transmitted to the left scapular and axillary regions.

The urinalysis showed sp. gr. 1010, acid, dark in color, with faint traces of albumen, but no sugar. Microscopic examination showed the dark color to be due to numerous dark brown or black pigment granules. The patient complains only of weakness and occasional pains in the more prominent tumors. Pulse 92; temperature and respiration normal. Ordered citrate of iron and quinine, grs. v, and opium gr. ss t. d.

September 2.—His stools are jet black.

3d.—He complains of intense burning pain in some of the tumors. Ordered morphia gr. ¼ every two hours.

9th.—Began to complain of obstinate nausea and constipation, apparently the result of the opiates given to relieve pain.

October 12.—At present there are about one thousand tumors visible over the body, most of them pigmented, bluish-black in color. Many are quite small, having developed since the last count was made. During the latter part of September the foreskin became indurated and swollen. This condition showed great variations, the foreskin being at times very much swollen and at others normal. The patient's strength failed rapidly. His skin became much darker in color, and the areas of pigmentation around the tumors in some places coalesced. Seeing the inevitable end of his sickness he desired to be with his family, and was discharged from the hospital at his own request.

He was under the care of Prof. P. S. Conner the last four weeks of his stay in the hospital. After leaving this institution he was treated by his family physician, Dr. W. H. Taylor, to whom we are indebted for the following brief note of his condition while under his observation: His strength failed rapidly and he suffered so much that it was necessary to keep him constantly under the influence of opiates. He died from exhaustion October 18.

A post-mortem examination was made the next day by Dr. Thompson assisted by Drs. Taylor, Langdon, and Walker, and the following results noted: Body that of a man of medium size, and very much emaciated. Rigor mortis slight. The skin was generally dark in color, but in some places had an ashen hue.

Over the entire surface of the body numerous tumors could be seen, mostly of small size. Some of the tumors were bluish-black, while others did not differ in color from that of the skin. On making the first incision and laying back the flaps it was seen that all the tumors were alike pigmented, the difference in color before noted being due to the involvement of the skin in the morbid growth over those that appeared black, while the others were limited to the subcutaneous cellular tissue. There were several tumors about the size of a hazelnut in the substance of the right pectoralis major muscle. The lungs were œdematous, jet-black in color, but contained no tumors. There were slight pleuritic adhesions over both lungs and an old cicatrix in the lower lobe of the right lung.

There were several small tumors in the muscular substance of the heart. In the subserous connective tissue over the left ventricle was a large patch of jet-black pigment. Some calcareous nodules were found in the aortic valves. The other valves appeared normal and competent.

The liver was firm, markedly pigmented, and contained numerous tumors, some as large as a walnut. Several of these large tumors were encapsulated.

The spleen was very deeply pigmented, and its tissues soft and friable, but it contained no tumors. A small supernumerary spleen was found.

The kidneys were enlarged, deeply pigmented, and each kidney contained several tumors varying in size from that of a pea to that of a hazelnut.

There were numerous tumors about the size of a pea in the subserous connective tissue throughout the whole length of the large and small intestine, and numerous similar growths in the great omentum and beneath the parietal peritoneum.

One small tumor was found projecting from the mucous lining of the bladder.

Owing to the objection of relatives, the brain was not examined.

Specimens of the tumors when subjected to microscopic examination, showed the characteristic structure of sarcomata.

There are very few cases on record similar to the one above reported. On October 10, 1882 Dr. William H. Falls of this city, presented to the Cincinnati Medical Society the report of a case of melanosis.

Digitized by Google

The case was that of a man at Greenville, Ohio, who had several small tumors—diagnosed congenital nævi—removed, after which operation there developed a number of pigmented nodules in and beneath the skin, accompanied by a general pigmentation of the skin, which eventually became so dark that the patient was easily mistaken for a negro. Dr. Falls, in his report, has not only given a thoroughly scientific account of his case together with the results of the post mortem and microscopic examination, but he has brought together almost, if not quite all that was known up to that time of this strange condition. Dr. Falls's paper was published in the Cincinnati *Lancet and Clinic*, November 18, 1882, and afterwards republished in pamphlet form, so that it is quite accessible to the profession.

In vol. xxxv., 1884, of the *Transactions of the Pathological Society of London*, a very interesting case of melano-sarcoma with subsequent general pigmentation of the body, formation of pigmented nodules in the skin and internal organs, is recorded by Dr. J. Wickham Legg. As the reports of the Pathological Society are not to be found, except in the larger libraries, a synopsis of the case is given. Dr. Legg's own words are used except where changes and omissions are required in order to condense the report. "James H., a carpenter, was admitted into St. Bartholomew's Hospital under my care July 1, 1883. His left eye was taken out on November 14, 1881, at the Royal London Ophthalmic Hospital, Moorfields, by Mr. Streatfeild, to whom I am indebted for the following particulars: Four months before, the left eye had felt tight and gummy, not acting with the right. No pain was felt. A solid growth could be seen involving the retina. When the eye was excised a soft tumor was found filling up the outer half of the globe. It was a black growth in the outer part of the ciliary region, firmly adherent to the sclerotic.

"Under the microscope the black tumor proved to be a spindle-celled sarcoma with a large quantity of pigment irregularly scattered through it.

"The patient left Moorfields November 19, 1881. For a fortnight before his admission to St. Bartholomew's, his belly had been hard and uncomfortable, and for a year it had been painful when pressed. The legs have been swollen for the last six weeks, the scrotum and penis, a fortnight. Almost six months ago he was told that his face was getting dark. The appearance of the face so strongly suggested staining by nitrate of silver that he was carefully questioned as to his use of this salt. A most thorough investigation showed that he had never used nitrate of silver in any shape, nor had it ever been used locally or internally in his case by any of the physicians or surgeons who had treated him at various periods of his life.

"The pigmentation of the face was uniform and not in patches or spots. Under the beard on the right side of the chin was a little black wen, or wart. The teeth had nearly all fallen from their sockets. No pigmentation of the mucous membrane of the mouth was noticed. The darkening was most marked over the face and neck. It was present on the hands, but very little over the rest of the body.

"Heart and lungs normal on examination. The belly was swollen. On the right side a tumor, continuous with the liver dulness, extended to the right iliac fossa. In the epigastrium a small nodule could be felt, making itself prominent above the general level of the surface of the tumor. This nodule was very painful on pressure. The spleen could not be felt. The belly was dull in the left flank, the dulness changing with the position of the patient. The urine was of a dark dirty-brown color, turbid, but clearing on heating. It contained albumen. No blood corpuscles were found.

"*July 13.*—Patient getting weaker. Liver very painful.

"*25th.*—Under the microscope the blood showed no dark granules, but an abundance of bodies of varying size and shape, usually very large and very irregular, looking like masses of white corpuscles fused together.

"*August 1.*—Urine gives deep brown color with hydrochloric acid and chloride of calcium which deepens, on standing, to black. No dark granules have ever been found in the urine.

"Died August 1. Examination twenty-six hours after death.

"Calvaria and brain natural. No recurrence of disease in the left orbit. Choroid plexus of brain not stained. On opening the belly, an abundance of dark colored fluid escaped. Liver adherent to abdominal walls, omentum, colon, and stomach. There are hemorrhages in the peritoneum.

"Four or five small dark spots in the endocardium on the right as well as the left side. A few small, firm, white nodules in the omentum and capsule of the spleen. Intestines, stomach, and pancreas natural.

"In the hilus of the liver there are several large glands, some dark, one cheesy and white. Gall-ducts free, gall-bladder collapsed. No thrombus in the portal vein. Liver weighs 5700 grammes. Numerous black and white spots are seen through the capsule. Section shows little of the normal liver tissue, the organ being filled up with numerous black rounded tumors, varying in size from a pin's point to a walnut. A few white tumors varying in size from a pin's point to a filbert, but no tumors showing an admixture of black and white. Diaphragm shows numerous small growths, both on the pleural and peritoneal surfaces. Left kidney contains a black rounded tumor the size of a filbert. None in right. After proper preparation, the growths from the various organs and the skin were examined under the microscope, and proved to be melanotic spindle-celled sarcomata in the case of the pigmented growths and round-celled sarcomata in the case of the colorless growths. The distribution of the pigment was very irregular in the black tumors. The skin near the wart on the face showed brown staining in the deep layer of the rete mucosum but no distinct pigment granules were discovered.

"Mr. Butler, who saw the case with me, called my attention to Clausel's thesis, and told me that this observer had discovered pigment granules in the blood, the urine, and the vomit of patients suffering from melanotic sarcomata. Nepveu first called attention to the appearance of pigment granules in the

Digitized by Google

blood and urine of these patients in a communication to the Society of Biology (Paris) in 1872. In our case there was the excess of white corpuscles described by Nepveu, but no pigment granules.

"While the urine was dark-colored, no black granules or black casts were found. This absence of granules in so widespread a case of multiple melanosis, is important, as Nepveu considers the presence of the black granules in the blood and in the urine a contraindication to operation; and if a surgeon had considered their absence to be a justification for an operation, he would have been seriously mistaken."

It is the aim of this paper to bring the literature of this subject to date. There are a few cases which are recorded in medical journals not within reach of the writer. We know comparatively little of the process by which pigment is deposited in tissues; we know less of the changes which take place in the blood whereby a general tendency to pigment deposit is developed.

Cases are on record where nævi have been transformed into sarcomata. Were the nævi which were removed in the cases where multiple melanosis afterwards developed in process of transformation at the time of surgical interference? Did this surgical interference open up ways by which the elements of the malignant growths entered directly or indirectly the circulation producing the disastrous general dissemination?

Were the seeds already sown in the blood when the surgeon's knife was brought into requisition, and did the operation of removing a nævus or suspicious growth have no bearing on the after extension of the condition?

Can the surgeon, in a case of doubtful tumor, or where the diagnosis is clear as to sarcoma, derive any useful points from the microscopic examination of the blood and urine?

Do not such cases as the case of Williams and others point to the need of an early removal of congenital nævi, warts, moles, etc.?

These are practical questions which our clinical records will not as yet permit us to answer, but which should be kept in mind in future observations.

MEDICAL PROGRESS.

COCAINE IN HAY FEVER.—The therapeutical uses of cocaine are so numerous that the value of this wonderful remedy seems only beginning to be appreciated. Almost daily we hear of some disease or combination of symptoms in which it has been tried for the first time and has answered beyond expectation. It appears strange that so intractable a complaint as hay fever should be amenable to its influence, and yet such is the case. The account given by Mr. Watson, of the Westminister Hospital, of his sufferings and subsequent cure by tabloids of cocaine, is too circumstantial to admit of doubt, even had we not received confirmatory evidence from many sources. It has been objected on theoretical grounds that cocaine must of necessity be inoperative, or at all events of comparatively little use, in those cases in which symptoms of an asthmatic type prevail. Curiously enough, however, it has been shown that cocaine, when applied to the mucous membrane of the nostrils, has the power of allaying even this spasm. The observation, too, is not new; for many months ago Dr. Bosworth, Professor of Laryngology at Bellevue Hospital Medical College, published a detailed account of a case of spasmodic asthma completely cured by cocaine. He pointed out at the time that many inveterate cases of asthma are dependent on, or at all events associated with, nasal disorders, the relief of which is promptly followed by an abatement of all the distressing symptoms. If this principle of associated treatment should be carried on in its integrity, it will be difficult to assign the limits of its sphere of action.—*The Lancet*, July 18, 1885.

ALBUMINURIA: ITS CAUSES AND VARIETIES.—SENATOR, in the *Berliner med. Wochenschrift*, No. 16, April 20, 1885, enumerates the following conditions liable to determine the presence of albumen in appreciable amount in the urine:

Disturbances of the renal circulation. High pressure, if the urine be concentrated, should produce albumen. This condition is actually found to obtain by muscular action, on account of perspiration and loss of fluid by the lungs, and, though not so accurately, by elevation of temperature.

Passive hyperæmia acts in itself similarly to increased arterial tension, but the distended veins in the medulla of the kidneys press together the urinary tubes, leading to obstruction of the passage of urine and œdema of the kidneys. The consequence is:

a. That albumen transudes from the interstitial capillaries into the urinary tubes.

b. That urine exerting pressure upon the glomeruli produces a diminution of pressure from the glomeruli, and leads to a relative increase of excretion of albumen. To this cause of albuminuria is allied that caused by blocking of the urinary tract, manifested when the impediment is removed, or when the obstruction is not complete.

c. The condition of the filtering membrane, as in inflammation, fatty degeneration, and amyloid change. Not only does albuminuria result from an increased permeability, but the degenerated membranes and epithelium themselves appear in the urine as albumens, and this may explain the fact that in the urine albumens may have a different relation to each other from what exists in the blood. The substance of the epithelium appears to contain a body intimately allied with globulin.

d. The composition of the blood may cause the appearance of albumen, *e.g.*, from an excess of nutriment, from increased dissolution of albumen, or from excessive secretion of water elsewhere, etc. It is held by Rosenbach, that the composition of the blood is constantly regulated by the action of the kidneys, and that inassimilable albumen is excreted by the kidneys. Albuminuria not caused by inflammation, this author designates as "regulatory." His idea, though important, is not free from objections.

Finally, as Stokvis and Lehman have pointed out, the excretion of albumen can act injuriously on the kidneys.

e. Mention has already been made of the influence of temperature in connection with changes of pressure.

Digitized by Google

The author further remarks tha the forms of albuminuria may be clinically divided into two classes, pathological and physiological, although no exact line of demarcation distinguishes them. Among physiological albuminurias may be mentioned that of the newborn, which is probably due to the suddenly increased pressure in the glomeruli, taken in connection with the probably increased destruction of the blood-corpuscles.

Albuminuria can exist in a healthy man for years without any sign of ill-health, and then cease.

Fürbringer, too, has found this condition in children, in whom chronic nephritis is very rare.

The author, in this connection, alludes to the albuminuria due to mental perturbation, and to that caused by cold baths.

Pathological albuminuria includes the following:

1. That present in non-febrile diseases, in which the composition of the blood is specially concerned, and in which the kidneys do not participate to any extent; in anæmia, leukæmia, and pseudo-leukæmia; in scurvy, in icterus, and in certain cases of diabetes. Nothing is found in the urine indicative of renal disease.

2. Albuminuria in non-febrile nervous diseases, in epileptic seizures, delirium tremens, cerebral apoplexy, neurasthenia, migraine, Basedow's disease, etc., and allowing for other existing causes, numerous cases exist where the albuminuria is traceable only to the nervous condition.

3. Febrile albuminuria. In this condition there is a combination of favoring causes, such as high temperature, febrile changes in the circulation and in the composition of the blood, with consequent disturbance of the nutrition of the kidneys, and, lastly, concentration of urine.

4. Albuminuria of passive hyperæmia.

5. That due to blocking of the urine.

6. The albuminuria of pregnancy due to various causes, disturbance of the lesser circulation, passive hyperæmia due to abdominal pressure on the vessels, and constriction of the ureters.

7. That due to diffuse inflammation and degeneration of the kidneys (acute nephritis, subacute and chronic and amyloid degeneration).

8. That depending on circumscribed affections of the kidneys, such as infarcts, abscesses, and tumors.

In conclusion, the author insists on the necessity of constantly remembering that the treatment of each individual case of albuminuria varies with the exciting cause.

GASTROSTOMY IN LEYDEN.—PROF. VAN ITERSON, of Leyden, has published notes of two interesting cases in which he performed gastrostomy. The first case was that of a gentleman, aged fifty, who had carcinoma of the œsophagus, and who had been unable to swallow any food for several days before the operation, and was consequently reduced to a state of great emaciation and debility. The abdominal wall was opened and the stomach fastened to it, arrangements being made for supporting life by means of nutrient enemata until it should be thought safe to open the stomach. Collapse, however, came on shortly after the operation, and death supervened. The Professor says, that if he had another similar case he would open the stomach at a single operation. The second case was more satisfactory, and was that of a painter, aged fifty-seven, who suffered from a carcinomatous tumor affecting the suprascapular region, the neck, pharynx, œsophagus, and larynx. When seen in July, 1884, he had had difficulty in swallowing for about a year, the last four months of which time he had been unable to take any solid food. A small bougie (No. 27 Charrière) was with great difficulty passed through the stricture. The first part of the operation was performed on the 16th of July under an anæsthetic, with antiseptics, but without spray, and consisted in opening the abdominal wall, lifting aside the liver, seizing the wall of the stomach as high up as possible, and attaching it with ligatures very carefully to the abdominal wound. This was dressed with powdered iodoform and salicylic wool. The patient was supported by nutrient peptonized enemata for six days, when an opening was made in the stomach with the galvano-cautery sufficient to admit the end of a three-quarter centimetre India-rubber tube; the other end of this was provided with a funnel. At first, liquid nourishment was administered through this; then solid food was chewed in the mouth and spat into the funnel, the India-rubber tube being thus an artificial œsophagus. The patient expressed himself as well satisfied by this method of feeding. He left the hospital three months after the operation. Two months later (November) he returned, complaining of dyspnœa from obstruction of the larynx. Tracheotomy was performed, and a month later it was noted that his daily nourishment consisted of five slices of bread, two eggs, one cup of soup, one beer-glass of port wine, one ounce of raw beefsteak with potatoes, greens, and rice, and one litre of milk. Two months later, or eight months after the operation, the malignant tumor increased considerably, and hemorrhage occurred, which in a few days induced a fatal termination of the case. At the autopsy the stomach was found attached to the abdominal wall for about the size of the surface of a dollar. The fistula was 70 millimetres to the left of the cardia, 240 from the pylorus, and 40 from the insertion of the omentum. The mucous membrane was pale, but healthy; above, the stomach was found adherent to the diaphragm. Frofessor van Iterson remarks that few cases have lived eight months and a week after this operation. He agrees with the advice given by other surgeons that the opening into the stomach should be as far as possible from the pylorus. In both cases he was able by means of a sharp hook to bring the most suitable portion of the stomach to the wound.—*The Lancet*, August 8, 1885.

STRANGULATED UMBILICAL HERNIA. REMOVAL OF SIX INCHES OF SMALL INTESTINE. RECOVERY.—MR. W. H. FALKER reports a case of strangulated hernia resulting in recovery after removal of six inches of the small intestine. The patient, a woman aged forty-seven was admitted to the infirmary suffering from strangulated umbilical hernia. About twelve years ago, whilst carrying a basket, she suddenly felt something give way at the umbilicus, and a swelling arose, accompanied by pain and sickness. These symptoms subsided in three days, but since that time she had had several recurrences, generally lasting only a few hours, and being relieved by her assuming a recumbent position.

On February 25th, the patient had a return of all the symptoms, but attended with a burning pain, which continued to increase. She was induced to send for a

Digitized by Google

medical man, who urged her to apply at once to the infirmary. At first she declined, but the pain and sickness increasing, she came in on the 28th.

On admission, the patient, a corpulent woman, appeared to be in a most exhausted condition, suffering from almost constant vomiting of a fecal character. She had a large umbilical hernia, evidently not only strangulated, but gangrenous, for even the skin covering it was quite black, and smelt most offensively.

Immediate operation was resorted to, the patient being cautiously etherized. An incision was made, of the length of the tumor, opening the sac, when a large piece of bowel was found to be quite black, the contents having escaped into the sac through an opening about an inch and a half in length; the omentum and everything within the incision was gangrenous. The skin and everything that was sloughing, except the bowel, was first removed, and the cavity well washed out with carbolic lotion, and then the bowel (which was small intestine) was drawn well forward till a sound portion was reached at each side; the inner halves of each portion were cut through and carefully stitched together, with their peritoneal surfaces in contact, the outer half of each piece of bowel affording a secure hold whilst this was being done; these were then removed, and the cut edges secured to the skin, forming an artificial anus. The edges of the skin below were brought together by two harelip-pins, and the parts dressed with oiled lint (carbolic oil 1 in 20), covered with absorbent wool, a wide flannel roller being applied over all. She was ordered to have the urine drawn regularly with the catheter, and to take ice and soda-water.

February 29th (the day following the operation). The temperature was normal. There was fecal discharge from the bowel-opening. The patient was looking better, although vomiting, with a fecal odor, still continued, and she had some little pain. A subcutaneous injection of morphia was given, which relieved the pain and checked the sickness. The skin over the abdomen was covered with oxide of zinc ointment spread on lint.

April 9th, the patient informed the physician in charge of her probable pregnancy; examination showed her to be so and after consultation abortion was performed, from which she recovered fully.

All efforts to close the artificial opening in the bowel were ineffectual. By the use of enemata a natural motion first occurred on June 23d and again on June 26th. Efforts again repeated to close the external wound by refreshing its edges and suturing them were all unsuccessful. September 22d, a motion of the bowels occurred for the firs time without enemata, and again on the 29th. This did not occur again, and enemata were once more resorted to and always with good result. Fecal matter, however, continued to well up through the wound, though it was reduced to the size of a three-penny piece.

The woman was discharged at her own request, and remains exactly in the same condition as when she left the infirmary.—*British Medical Journal*, August 15, 1885.

LEAD POISONING BY LONG-CONTINUED PAINTING OF THE FACE.—PROF. ROSENTHAL recently showed, at the Society of Physicians of Vienna, an interesting case which had been under his treatment as an out-patient at the "Allegemeines Krankenhaus." The patient, an actor, aged thirty-seven, had long noticed an emaciation of the fingers of his right hand. Prof. Rosenthal found, on examination with the electrical current, a loss of power and of faradic irritability in the common extensors of the fingers, and in the lumbricales as well as in the fourth interosseous; galvanic contractility was not lost. The supinator longus was not affected, but the irritability of the radial nerve was much diminished. The left hand was normal, except that the power of abducting the thumb was somewhat impaired. The idea that it was a case of paralysis caused by pressure was abandoned in view of the slow development of the case, the implication of the fourth interosseous muscle, and the normal state of the supinator. Progressive muscular atrophy was also excluded, as the development and reaction of the muscles of the thumb were normal, and there was no muscular atrophy of the arm, though the irritability was diminished. The whole complex of symptoms, however, induced Prof. Rosenthal to diagnosticate lead poisoning. He, therefore, had the gray and red paint that had been used examined by Prof. Ludwig, who found that both contained a considerable proportion of lead.—*Medical Times*, August 15, 1885.

THE TREATMENT OF SYPHILIS BY INJECTIONS OF CALOMEL.—V. WATRASZEWSKI, in the *Viertel Jahrschrift für Dermatologie und Syphilis*, Bd. xi., reports the subcutaneous injection of calomel in seventy cases of recent syphilis. With the exception of a few cases in which the dose was doubled, the drug was injected in quantities of one and a half grains in solution of cocaine. The injections were commonly made in the gluteal region at intervals varying from seven to ten or fifteen days.

In four instances only was it necessary to increase the intervals on account of mercurial stomatitis. As a rule, three injections were sufficient to cause abatement of the existing symptoms. A fourth injection was, however, generally administered. In only one case was a fifth injection necessary. In two hundred and fifty-seven injections, only four cases of abscess occurred, and these during the first weeks in which the injections were practised.

Inasmuch as abscess did not occur later, it is attributed to faulty injection or to some special condition. The local pain was slight and did not interfere either with the sleep or avocation of the patient.

However, Dr. v. Watraszewski advises that, during the first days after injection, the patient should not move about to any great extent or be permitted to do heavy work. He also calls special attention to the advantages of this method of treatment in reference to outdoor patients.—*Centralblatt für Chirurgie*, August 8, 1885.

ANTIPYRIN IN SCARLET FEVER.—DR. FREDERICO VANANZIO, after a clinical study of the use of antipyrin in scarlet fever, reaches the following conclusions:

1. Antipyrin certainly reduces the temperature in scarlet fever for a length of time and to an extent which vary with the dose and individual; but the fever, on the cessation of the action of the drug, returns with renewed intensity, even when, by the careful diligent use of the

Digitized by Google

remedy, it has been possible to suppress it for many hours in succession.

2. During the hyperthermia procured by the administration of antipyrin no appreciable improvement, either subjective or objective, is manifested by the patient, aside from the simple reduction of the fever.

Indeed, the ordinary syndromes and complications of the disease, such as pharyngo-laryngitis, adenitis, nephritis, gastro-enteritis, bronchitis, stupor, coma, etc., are neither prevented nor modified. In the toxic forms when it is desirable to reinforce the cardio-vascular tone antipyrin does not in the least oppose the advance of collapse.

3. Antipyrin does not exercise any favorable influence upon the ordinary duration of the disease. In some circumstances it seems rather to prolong the so-called stage of invasion, and to retard the appearance of the eruption, a fact which has already been noted in rubeola and measles.

4. In some subjects antipyrin induces mydriasis and symptoms of slight cerebral congestion and persistent vomiting which prostrates the patient.—*Gazzetta medica di Torino*, July 25, 1885.

VERATRIA IN THE TREATMENT OF GENERAL OR LOCALIZED PRURITUS.—DR. J. CHÉRON, in the *Lyons Médical*, remarking the difficulty experienced in the treatment of the pruritus often observed at the menopause, whether as due to prurigo, urticaria, eczema, or herpes, or as existing without an eruption, recommends the following ointment:

℞.—Veratria . . . . . gr. iiss.
Adeps . . . . . ʒj.—M.

Ft. unguent. S. Apply in quantities the size of a small pea, morning and evening, by gentle friction to the affected parts when the pruritus is localized in the groins, axillæ, or upon the abdominal wall.

When the pruritus is general the internal administration of the drug is advised:

℞.—Veratria . . . . . gr. ⅓.
Pulv. glycyrrhizæ . . . . q. s.—M.

Ft. pill No. xl.

S. 2 to 6 pills daily, a half hour before meals or three hours after.

A single pill should be taken as an initial dose, and an additional pill taken each day until a maximum of 6 pills daily has been reached.—*Journal de Médecine de Paris*, August 9, 1885.

HEMIPARESIS AND HEMIANÆSTHESIA FOLLOWING DIPHTHERIA.—PROF. ROSENTHAL, at a recent meeting of the Society of Physicians of Vienna, exhibited the following case occurring in his practice, which he considers to be unique. The patient, a girl aged fifteen, had suffered some weeks previously from an inflammation of the throat which got better after the use of a gargle without other medical treatment. The third week after her recovery she felt pains in the right arm and leg, the right hand was powerless to grasp anything, and she could not double her fist. About this time she began to talk through the nose, and the fluids which she took returned by the nostrils; even water could only be sipped occasionally. Diplopia was also complained of. Recently pains in the left leg also appeared, and the fingers of the right hand became insensible. When the patient was examined by Prof. Rosenthal in the sixth week there was paresis of the right arm, the mobility of which was impaired, the grasp of the hand was feeble, and there was loss of power in the right leg. The faradic reaction was everywhere normal, and the tendon reflex was also unaffected. The skin on the right side of the body was insensible to electrical as well as mechanical stimulation. The application of the faradic brush to the arm, the mamma, the abdominal wall, the nates, the thigh and legs, the nape of the neck, and the back, produced no pain, and the same was true of heat and cold. The palatine arch was displaced towards the left side, and both its right half and that of the pharynx, and, according to Dr. Chiari, who had examined the patient with the laryngoscope, the right half of the epiglottis as well suffered from impaired sensibility; besides which there was paresis of the right vocal cord. In the nerve plexus of the arm, and in the course of median and radial nerves on the right side, there were points which were tender on pressure, and the same were to be observed in the case of the peroneal nerve. The excitability of the fifth nerve and the sense of taste were impaired on the right side. There was no symptom of hysteria; and menstruation was regular. All the symptoms pointed to a conducting anæsthesia in the region of the right spinal roots and posterior branches which had been preceded by a condition of irritation. Pierret and Déjerine had found an infiltration of the nerve nucleus and proliferation of neuroglia in the nerve roots and nerve trunks after diphtheria.—*Medical Times*, August 15, 1885.

TERPINE.—R. LÉPINE, at the conclusion of an experimental study of terpine, makes the following résumé of the qualities of the drug:

Clinical observation proves that terpine when ingested is active, but harmless, even in large doses, except to those affected with renal disease, and with whom, on this account, the doses should be moderate. Introduced directly into the blood in doses no longer medicinal but toxic, besides the action which it exercises upon the nervous system, it tends to produce an excess of hæmoglobin in the blood, polycholia, and even hæmoglobinuria.—*Revue de Médecine*, August, 1885.

PARALYSIS OF THE LEFT ARM AND LEG, WITH A SINGULAR EFFECT ON THE PULSE OF THE SOUND ARM.—DR. A. T. GUNNING reports a case of paralysis of the right arm and leg, with singular effect upon the pulse of the sound arm. There was neither motion nor sensation on the affected side. Temperature on both sides was normal. Heart sounds normal but slow, no pulsations at the radial or brachial artery of the sound side. The pulse on the paralyzed side was 35, soft, and regular. During all the time the man was under treatment there was no return of the pulse on the right side, although its muscular power and movements were quite good.

The cause of the absence of pulse is obscure. Had there been embolism, some visible change in the arm would have been experienced, but of this there were no signs, neither numbness, pain, tenderness, swelling, pallor, nor gangrene.—*The Australian Medical Journal*, June 15, 1885.

THE CONTINUOUS OR SPIRAL CATGUT SUTURE IN GYNECOLOGY.

THE use of the continuous catgut suture in gynecology, especially in plastic operations, has, probably, not received in this country the attention it deserves. The remarkable successes, especially in perineorrhaphy and in perineoplasty, that have been attained with it abroad by Schroeder, Bröse, Bar, Veit, and others, entitle the method to be properly understood and fairly tried.

Among important contributions to the literature of the subject may be mentioned one by BRÖSE, *Arch. für Gynäkol.*, 1883, one by BAR, *Archives de Tocologie*, February, 1885, and a discussion upon the subject by the Berlin Obstetric and Gynecological Society, in connection with a paper by Schroeder, the report appearing in the *Centralblatt für Gynäkologie*, July 18th. A study of the subject chiefly in connection with these contributions may be interesting and valuable to our readers.

According to Schroeder, Graefe was the first to use the continuous catgut suture in a recent rupture of the perineum, but it was not until Küster devised the method of preparing the catgut in oil of juniper that these sutures dissolved in nine days.

Of course, the catgut must be completely aseptic, and in its preparation one has to avoid such changes as will prevent its too rapidly dissolving in the tissues, or its failure to dissolve at all. The latter accident, which has occurred to us in some cases from using the MacEwen catgut, is very trying to the patient and mortifying to the operator.

According to Bröse Number 2 Lister's catgut is a suitable size, but it is not to be prepared according to Lister's method. Apparently the best method of preparing it is, first, soak it twelve hours in Van Swieten's liquor, and then place it in oil of juniper; no definite period is stated for its remaining in the oil of juniper, but probably a few hours will be sufficient; afterward it is preserved for use in absolute alcohol, and immediately before being used is washed in a 4 per cent. solution of carbolic acid.

Schroeder thinks it of very great importance not to irritate the denuded surfaces in a perineoplasty in the process of cleansing them, and he is now using for the latter purpose only distilled—that is, sterilized water. Veit irrigates these surfaces with a 1 to 10,000 sublimate solution. The method of denuding the surfaces is immaterial, only care must be taken not to carry the denudation too far on the sides lest undue tension results.

After the surfaces have been freshened, the operator, taking a needle threaded with catgut, begins stitching at the upper, the vaginal angle of the wound; after passing the suture from one to the other side he may either knot, or tie the catgut, and he then stitches from side to side, making a continuous or spiral suture along the vaginal surface of the rent to the skin surface of the perineum. He may then continue with the same needle, sewing up the perineum with deep and with superficial sutures; or for the present leaving that needle and catgut, take another threaded needle, and begin the stitching of the perineum at the posterior portion of the rent, and when he has completed this by a similar spiral suture, remove the needles, and tie the two pieces of catgut together. Or the same result may be accomplished if only a single catgut suture has been used, since in knotting or tying the first stitch, one may leave a projecting piece, and to it the final end is tied, the initial and terminal portions being thus united. In case the tear of the perineum be complete, it is well to use stitches in the rectum, and these are taken in the same way as the vaginal, but, of course, should be made before the latter. Bar states that some operators regard it as important to knot the suture from time to time, this prevents separation of parts if the catgut should happen to break. So, too, even in the vaginal stitching if the depth of the fissure be great, it is of essential importance to have a series of deep, and then one of superficial sutures.

One should have three or four needles threaded, so that, if the catgut breaks, there will be no delay in continuing the operation; these needles and catgut are kept in the carbolized water mentioned. Schroeder mentions among the advantages of the continuous catgut suture the rapidity with which the operation can be done, the absence of bleeding, and the accuracy with which the torn surfaces can be brought and kept in contact.

After the operation he has the patient's lower

Digitized by Google

limbs fastened together, and keeps her in bed three weeks. To prevent distention of the rectum with fecal gases, he makes a subcutaneous division of the anal sphincter, and inserts a small tube in the rectum.

His results are of twenty-five operations upon twenty-four patients, all cured—one, as will be observed, had to have a second operation.

The results of colporrhaphy have also been much more favorable with the continuous catgut suture; posterior colporrhaphy gave more successes than anterior, the movements of the bladder interfering with perfect healing in the latter, a difficulty which he has endeavored to overcome by tamponing the vagina with iodoform cotton.

Odebrecht claims brilliant results from this suture, which he has adopted by the advice of Hofmeier; he has operated in three cases of rupture of the perineum, all of which succeeded; two of them being primary, the other a secondary operation. In one of his cases he used a rectal suture, introduced before the vaginal.

Veit's cases of perineal operation with catgut suture were seven, and six were successful. Beside, he had used this suture in thirty cases of prolapse operations, and two of vesico-vaginal fistula: the results were good.

Our own experience with the continuous catgut suture in gynecology has not been so great as to justify a conclusive opinion. The first difficulty we met, and which prevented success, was the unsuitable catgut used; some broke at almost every stitch, others split even after threading the needle and while taking the stitches, while still others refused to dissolve. Nevertheless, with catgut of suitable size and quality, and prepared as mentioned in this article, the results have been such as to encourage us to new trials.

INFECTIOUS PNEUMONIA.

MASSALONGO has described an epidemic of pneumonia in Tregnigo, a town in Italy of 2000 inhabitants, which presents certain points of interest. One hundred persons were attacked, of whom thirty died. No special atmospheric or telluric conditions preceded the outbreak, which was limited in extent, and spread from house to house, three, four, or five cases occurring in each one. The onset of the disease was rarely with a rigor, usually with malaise, headache, and indisposition for three or four days, rather resembling typhoid fever. The lung symptoms were usually marked, the expectoration rusty, but resolution was not often preceded by any critical phenomena, and took place very slowly, the patients remaining in a heavy, apathetic state. Delirium was frequent, and at times furious. Meningeal, articular, and renal complications were common, and hypertrophy of the spleen almost constant. During convalescence paralytic affections developed in three cases. After death it was observed that putrefaction supervened very rapidly. The characteristic microorganisms were found in the sputum. Many interesting facts are given in proof of the contagious nature of the disease.

There can be no doubt that this was an epidemic of an infectious disease with pulmonic lesions, but the mode of onset, course, and character of the symptoms seem very different, in many respects, from those of ordinary croupous pneumonia. Similar differences have been observed in other epidemics and the identity of the affections has been questioned by several observers.

A RECENT ARGUMENT FOR MATERNAL NURSING.

THE question of maternal nursing is an old one. It is probable that in the time of the Egyptian bondage, some women among the Israelites were wet nurses, else we cannot readily understand the disposition which Pharaoh's daughter at once made of the new-found infant Moses. Nevertheless the ancients were especially favorable to the mother's nursing her infant, because they believed that the latter sucked with the milk that nourished it, certain moral qualities. Among the bitter reproaches that the deserted Dido heaped upon the escaping Æneas was this, that he had nursed the breasts of Hyrcanian tigresses.

There is an interesting passage, a part of which illustrates this belief, found in Plutarch's sketch of Cato, the Censor: "As soon as he had a son born, though he had never such urgent business on his hands, unless it were some public matter, he would be by when his wife washed it and dressed it in swaddling clothes. For she herself suckled it, nay, she often, too, gave her breast to her servants' children, to produce, by their sucking the same milk, a kind of natural love in them to her son."

Nevertheless, all Roman women did not suckle their children, as is shown by the incident narrated by Livy concerning Gracchus, returning in triumph to Rome; he, seeing upon the walls his mother and his nurse, gave the latter a rich golden collar, to the former only a plain silver ring. So, too, Marcus Aurelius declared that she was only half a mother who gave birth to a child and did not suckle it. Upon some of the tombs of women dying in the time of Hadrian there have been found, as expressing the highest praise, these words: *Filios suos propriis uberibus educavit.*

Maternal nursing has been held so important that it has been urged, not only by physicians, philanthropists, political economists, and philosophers, but even presented as an imperative duty by some religious teachers. Two medical men very eminent in their day, Stahl and Van Helmont, were, however, exceptions to the general rule mentioned as to physi-

Digitized by Google

cians; they maintained that the mother's milk was not sufficient, and advised giving with it pap. Alas, that the pap doctrine ruled so long, and is still held by some who have the charge of infants, for the murder of unnumbered innocents has been its necessary result.

It is believed that the number of mothers who do not nurse their children increases rather than diminishes. Of those who thus fail in the natural complement of pregnancy, many cannot; the reasons for this inability, or disability, are in part given in the late Dr. Clarke's work upon *Sex in Education*, a work that should be in the hands of all parents and teachers of girls. Many others will not; they are unwilling to make the sacrifice of convenience, comfort, rest, and time which nursing an infant involves. It is hardly necessary to say that this sacrifice is very great, and only made in many cases with much pain, exhaustion, and weariness, and often only possible by the power of maternal love and the strength of consecration to duty. In the eloquent and bitter reproaches which are attributed to the mother of St. Simeon Stylites, when she found her son after twenty-seven years absence, and he refused to see her, she uttered these words: "My son, why have you done this? I bore you in my womb, and you have wrung my soul with grief. I gave you milk from my breast, and you have filled my eyes with tears."

When such an obvious duty as maternal nursing is so frequently neglected, it is important to repeat old and to present new arguments in its favor. The *Bulletin Général de Thérapeutique*, of July 15, contains an interesting article by DR. SÉJOURNET upon the influence of natural nursing in the treatment of diseases of young infants, in which some important facts are presented in favor of natural rather than artificial food for infants. The author's purpose is to show that the milk of the mother, or of the wet nurse, is the best of medicines, the most precious and the most certain of therapeutic means, which can be used against the diseases of the first year. Such food is still more valuable in a hygienic than in a therapeutic view, and renders more service in prophylaxis than in cure.

Séjournet states that in seven cases of convulsions from gastro-intestinal irritation, five of the infants were fed by the bottle, and only two at the breast. Teething occurred in 47 infants under a year old without producing any irritation; 24 of these were nourished exclusively by their mothers' milk till they were six months old, after which other food was added, and the 23 others were also nursed by their mothers, but beside had soup and panada. Of 41 infants who suffered from gastro-intestinal irritation, while teething, 11 had the breast alone up to six months, while the other 30 had a mixed diet, viz., the mother's milk and starch food. 15 children between six months and a year old had convulsions, and 7 of these were bottle-fed, while the others, though having the breast, also ate freely. As the author observes, these figures are instructive, and plead in favor of natural nourishment as a preventive of the diseases so frequent in early infancy.

In sickness the milk from the bottle or the glass designed to replace the mother's milk, is less easily digested and assimilated by the organism than the living milk, and therefore it has not the same strengthening and reparative properties.

In the territory under his observation, there were, Séjournet states, 302 deaths in the course of four years in a population of 4000, the number of infants dying in their first year being 57. Of these infants, 33.3 per cent. were nourished by the breast, while 66.7 per cent. had either been weaned, or had been brought up from the first by the bottle: he says that this difference would be still more striking if the infants in the first class had all been kept exclusively on their mothers' milk—that is, the mortality would have been much less than 33.3 per cent. The author shows from further statistics the greatly less mortality of infants at the breast than that of infants at the bottle, in various diseases, such as measles and broncho-pulmonary maladies.

The lesson which he seeks to inculcate is the importance of mothers' nursing their infants, and he believes it should be urged on them by physicians.

The plain truth of the observations of Séjournet, confirming those of others, is that the mother who can, and who will not give to her infant the nourishment nature provides and designs for it, runs the risk of being guilty of infanticide. Pliny, who was not surpassed by Paley in his faith in final causes, said that a woman's breasts were placed upon the upper part of her chest so that she might fondle and caress her infant while it drew from them its food. Those who have studied the development of the infant mind assert that a most important stage in that development occurs during the first year of life. It is when the infant is happiest in satisfying its hunger with nature's food, that the best, the gentlest moral influences flow in upon it, and the fashioning of its spiritual nature in beauty and virtue begin. Finally, the physician urging natural nursing, pleads the lessened morbility and mortality of infants thus nourished, thereby adding this argument to that derived from natural instinct, to that of caressing, and maternal love, and to that of maternal duty in the proper unfolding of the infant mind.

PHOSPHIDE OF ZINC IN DYSMENORRHŒA AND STERILITY.

IN Matthews Duncan's lectures on *Sterility in Woman*, he places dysmenorrhœa in the list of the best demonstrated sources of, or attendants on, such

Digitized by Google

conditions. But, even if we consider dysmenorrhœa the cause of the sterility, the question of the treatment of the menstrual difficulty does not in many cases admit of ready answer. Certainly there are cases of dysmenorrhœa which may be rapidly and satisfactorily treated by dilating the cervical canal, this dilatation being by double-bladed dilators, rather than by other means. But there remains a large number of cases that present no indication for this method of treatment, and which, of course, are not benefited if it be tried. Now, some of these may possibly be cured by the use of phosphide of zinc, as recommended by Decoux in a recent number of the *Gazette des Hôpitaux*. Having found this medicine useful in many cases of dysmenorrhœa and of amenorrhœa, DECOUX narrates a case where it twice proved effective in curing sterility associated with the former disorder. In addition to the success of this medicine in dysmenorrhœa, amenorrhœa, and sterility, he has found it remarkably useful in cases of hysteria, ataxia, anæmia, and neuralgia. He gives two granules of four milligrammes each, morning and evening. Only the crystallized preparation should be used, as the powder is inert. He states that its preparation is so difficult that, with a single exception, one scarcely find in commerce any but an impure product, which is partly or completely ineffective.

PUNISHMENT IN KIND.

AN ideal justice has proposed that all crimes should have such punishment as corresponds with their nature. Thus, he who commits murder has his life taken as a forfeit by law; he who steals, must restore the stolen money, and likewise be punished by a fine; he who inflicts bodily injury must have similar injury done himself. Human laws do in some cases, as in that of murder, recognize this principle. But the principle may be carried too far, as happened with the judge who was guided by it in his decision as to the punishment for causing a miscarriage: A careless hodman, ascending a ladder, let part of his load fall upon a pregnant woman who was passing on the pavement, and as a consequence of the injury she miscarried, when the judge to whom the matter was referred by the indignant husband, decided that the hodman must place the unfortunate woman in the condition she was at the time of the accident. Probably the decision was not enforced, and in this respect there was a miscarriage of justice.

But occasionally punishment in kind is very justly inflicted without the intervention of law. A very striking illustration in point is given in one of the recently published lectures by Martineau, *sur la Blenorrhagia chez la Femme*. The story is this: A Parisian husband gave his wife gonorrhœa, and she *kept it for him* during more than two years! He was cured of the disease, but at more or less frequent intervals after coition with her, had fresh attacks, although she was supposed to have also been cured. Martineau, upon examining the lady, found there were two or three urethral and periurethral follicles projecting and purulent, that the vulval follicles near the opening of the excretory duct of the right vulvovaginal gland were also inflamed, as well as the gland itself, and that there was a sero-purulent urethral discharge.

No one can question the justice of the punishment for the husband's original sin. Unfortunately the moral of the story is in part spoiled by the statement that this man had intercourse with other women without contracting gonorrhœa, during the time his wife was so sure to give it to him under similar circumstances.

REVIEWS.

ON SCLEROSIS OF THE SPINAL CORD, INCLUDING LOCOMOTOR ATAXIA, ETC. By JULIUS ALTHAUS, M.D., M.R.C.P. Lond. New York: G. P. Putnam's Sons, 1885.

IN no department of medicine has such satisfactory progress been made of late years as in the diseases of the cord, and the number of excellent manuals which have been issued recently bears testimony to the general interest which the profession now takes in the subject. Dr. Althaus, who is a well-known London specialist of large experience, has chosen for consideration in this volume those diseases of the cord accompanied by sclerosis or chronic degeneration, and which include in reality the majority of cases of spinal disease commonly met with. Locomotor ataxia occupies three-fourths of the work, and is most exhaustively discussed in all its relations. Indeed, this part forms a complete monograph on the subject. The author is a strong supporter of the theory of the syphilitic origin of tabes, and in over 86 per cent. of his cases a specific history could be obtained. Certainly, so far as statistics go, the conclusion would seem to be warranted, and yet the dissimilarity of the lesions and the uselessness of special treatment outweigh in the minds of many authorities, such as Leyden and Westphal, any number of figures which may be "made to prove anything." Nearly 150 pages are devoted to the symptomatology of the disease, and many illustrative cases are given. In the treatment of tabes, Dr. Althaus, as is well known, holds much more hopeful views than most writers on the subject. Believing so strongly in the etiological relation of syphilis to this truly dreadful disease, he pleads earnestly with the general practitioner to be more alert in the prevention of it by thoroughly treating all cases of primary syphilis. Where there is a suspicion of this disease, a prolonged course of mercury and iodide of potassium is advised, and in the early pre-ataxic stage the progress of the disease appears to have been arrested. In the second and third stages not much can be expected from them, and the author then prefers ergot and nitrate of silver. Opinions differ much as to the value of the latter salt, but the author speaks in most favorable terms of

Digitized by Google

its use, particularly in allaying the pains. Discoloration is not produced until 450 grains have been taken (Krahmer), so that the drug should be stopped when the amount reaches about 300 grains.

We are glad to see that Dr. Althaus uses the term "Westphal's symptom," in speaking of the knee-jerk. The name of this able and modest[1] investigator should certainly be connected with the discovery of a symptom of such great value in diagnosis.

The chapters on spastic paralysis, Friedreich's disease, and insular sclerosis are equally interesting and full of valuable information.

SOCIETY PROCEEDINGS.

THE AMERICAN DERMATOLOGICAL ASSOCIATION.

Ninth Annual Meeting, held at the Indian Harbor Hotel, Greenwich, Conn., August 26, 27, and 28, 1885.

WEDNESDAY, AUGUST 26TH.

MORNING SESSION.

THE meeting was called to order at 10 o'clock by THE PRESIDENT, DR. W. A. HARDAWAY, of St. Louis.

The first paper was read by DR. J. E. GRAHAM, of Toronto, Canada. It was entitled

A CASE OF TUBERCULO-ULCERATIVE SYPHILIDE OF HEREDITARY ORIGIN.

The patient was a girl twenty years of age. On the right arm, from the wrist to the elbow, there was very little healthy skin, there being little but cicatricial tissue. The skin of the forearm presented elevations and depressions and in places was covered with thin scales. The hand was not involved and the affection did not extend deeper than the subcutaneous areolar tissue. For three or four inches above the elbow, the arm was atrophied and covered with cicatricial tissue. At the upper border of the cicatricial tissue, was an ulcer three-fourths of an inch wide, which encircled the arm. Above this there was sound tissue, no nodules were present. The left clavicle presented, about its middle, a swelling and ulceration about the size of a silver dollar; the result of a blow. There was no copper-colored appearance. The heart and lungs were healthy and the urine normal. Investigation of the family history showed that the mother was apparently healthy, and the patient's sisters, three in number, all younger than herself, were healthy. The father died of pneumonia when the patient was eighteen months old; it was subsequently learned (after the patient had been under treatment for some time) that he had also had syphilitic ulceration of the throat. The treatment consisted in the local application of a mild mercural ointment and the internal use of corrosive sublimate and iodide of potassium. The condition steadily improved and in the course of six or eight weeks the ulceration had healed. Since that time the patient had not been under observation.

The speaker referred to the difficulties of diagnosis in this case, as there was, at first, a complete absence of specific history, the facts in regard to the father not being learned for some time after the case had been under treatment, and as there had been no previous evidence of hereditary syphilis; but taking all the facts into consideration, he thought that there could be no doubt as to the correctness of his diagnosis.

Photographs of the case were exhibited.

DR. R. W. TAYLOR, of New York, said that there are a number of important points brought up by this paper. First as regards the family history. The mother was healthy, but the father had syphilis. It is now generally conceded that syphilis can be communicated to the child without infection of the mother, and he believed that he was the first in this country to call attention to this fact. He has seen this a number of times and it has been in cases in which a most careful and thorough examination of the mother had been made and the observations continued over a series of years. Dr. Graham stated that he could obtain no history of early manifestations of hereditary syphilis. This is not uncommon, but Dr. Taylor believes that there is usually some indication of specific taint, but it may be so slight as not to excite notice or its exact import is not recognized. These may pass away and in the course of six months or a year, the ulcerative lesions appear, although it is not uncommon for the child to go to the age of from six to eighteen years without exhibiting this condition. He has reported the case of a girl whose mother had syphilis who had exhibited no signs of hereditary disease during her early years. When about fifteen years of age, she had, following a cold bath, the development of ulcerative gummatous tumors scattered over the entire body. A factor which has some importance in the time of appearance of these lesions is traumatism, as he has frequently noticed such instances.

DR. C. HEITZMANN, of New York, said that every one has seen cases similar to the one reported. He has seen such cases in which he was unable to determine at first sight the nature of the affection. The diagnosis lies between syphilis and scrofula. Lately a man aged twenty came to him with a condition similar to that described by Dr. Graham, affecting the right groin. The ulcer was ten inches in diameter. He was unable at first to make the diagnosis.

DR. GREENOUGH, of Boston, referred to the practical point to which Dr. Taylor has called attention, and that is the possibility of the father's infecting his progeny, without the mother showing any signs of syphilis. Within the past two months, he had seen a woman who has lost three children in succession from hereditary syphilis, yet she is strong and apparently perfectly healthy and has never shown any signs of the disease. This woman has been under competent medical observation for six or seven years.

DR. J. C. WHITE, of Boston, thought that in many of these cases it is impossible to make the diagnosis at once.

DR. L. A. DUHRING, of Philadelphia, said that there are certain cases in which it is almost impossible to express a positive diagnosis at first. The result of treatment in causing a rapid cure in the case described would certainly incline him to the opinion that this was a case of syphilitic disease. He has, however, never seen a case recover so quickly.

[1] We say "modest," for this characteristic struck the writer very forcibly when attending Westphal's Lectures on Diseases of the Spinal Cord. In an able discussion on the value of the knee-jerk, not a word was said of his own connection with the important discovery.

Digitized by Google

DR. J. NEVINS HYDE, of Chicago, said that, as regards the remarks of Dr. Taylor, he would say that he has seen cases which have convinced him that, whilst it is not the rule, still occasionally syphilitic children are born where, so far as observation can be made, no evidence of syphilis in the mother can be detected. As far as the general health is concerned, he cannot say that he has seen vigorous, healthy women the mothers of syphilitic children. Such mothers are usually pallid and weak, although there may be no symptoms which can be ascribed to syphilis. He sees inherited syphilis in infants constantly, but he has never seen inherited syphilis manifest itself in advanced years, or, if he has, he has failed to make the proper diagnosis. Tardy inherited syphilis he knows nothing about. The more he sees of syphilis, the more he is satisfied that in its origin heredity does not amount to very much. The accidental cases of syphilis are very common. He has seen the initial lesion of syphilis on the head of a penis where it was without doubt due to inoculation from the finger of the surgeon in catheterization. He has no doubt that the case described was one of syphilitic trouble, and, as Dr. Duhring has said, the result of treatment unquestionably points in that direction. There are no cases which yield so readily as old cases of untreated syphilis. As to pronouncing it a case of hereditary syphilis, his experience would not permit him to do so.

DR. W. A. HARDAWAY, of St. Louis, thought it unwise to base our diagnosis on the results of internal treatment. Because a case gets well under antisyphilitic treatment, is not proof that the affection is syphilitic in its nature. Local treatment alone will often produce that result.

DR. R. W. TAYLOR, of New York, remarked that Dr. Hyde had made the statement that these women apparently unsyphilitic, who have borne syphilitic children have, in his experience, been pallid and weak. He entirely disagrees with him on this point. More frequently he finds such persons in robust health.

The next paper was entitled

CLINICAL NOTES ON PSORIASIS,

by DR. F. B. GREENOUGH, of Boston.

The paper was ounded on the records of 394 cases of psoriasis, occurring in an observation embracing about 15,000 cases of skin disease, representing about two and one-half per cent.; 206 of these cases were males and 188 females. The author's statistics were presented, showing the age at which the attack was first observed. A large proportion was first attacked with the disease between the ages of ten and forty years; one-seventh before the age of ten years; this latter observation is not in accordance with the literature of the disease. In but ninety-seven cases was the speaker able to get reliable evidence in regard to the family history; in thirty-one of these psoriasis had existed in a near relative, but in the remaining sixty-six no other member of the family, near or remote, had had the disease.

As regards locality affected, where there is much development it is almost constantly found about the elbow and knees, and more frequently on the extensor surfaces than on the flexors. A class of cases is met with in which the affection shows itself only on the skin of the leg below the knee.

Well-marked cases are readily recognized, but in some cases there is considerable difficulty in making the diagnosis. It is most frequently confounded with some form of eruption resulting from constitutional syphilis. When psoriasis affects the scalp, its appearance is often similar to that of secondary syphilis. In psoriasis, however, the patch consists simply of epithelial cells, usually on a slightly hyperæmic base; in syphilitic eruption, the crust will contain other elements than epithelial cells, and on removal of the crust spots of moisture will be detected. A characteristic symptom of psoriasis of the scalp is a band of hyperæmia, about three-fourths of an inch wide, extending around the forehead, contiguous to the hair; this is a point of value in the diagnosis between eczema capitis and psoriasis. In the former affection, this band is wanting. In eczema, also, evidence of dried serum or pus will be found; eczema is apt to extend to the ears. Psoriasis is not accompanied with enlargement of the post-cervical glands, as is eczema. The diagnosis from favus is made by the age of the patient, a moist surface beneath the crust, the evidences of destruction of the hair follicles, and in favus the microscopical examination.

The speaker had never been able to satisfy himself that psoriasis of the scalp ever caused permanent loss of the hair.

On the general integument, syphilide are most apt to resemble psoriasis. The regions on which the eruptions appear are important. The syphilides are apt to affect the flexor surfaces, while psoriasis affects more commonly the extensor aspects. Psoriasis begins as a minute point of hyperæmia, which may last for several days. In macular syphilide a crop of macules appears within twenty-four or forty-eight hours, and then the eruption begins to fade. There is in syphilis a decided pigmentary change. In squamous syphilis, the epithelial scales differ from those of psoriasis.

The amount of pruritus complained of in psoriasis varies, but it is rarely a prominent symptom, although in exceptional cases it may be severe. He has never seen any eruption on the palms or soles resembling psoriasis, with the exception of eczema, which was not syphilitic.

In regard to treatment, some cases do well, while others do not. There is no specific; what will benefit one case may make another worse. In his experience, tarry preparations, especially the oil of cade, have been most efficacious. Great comfort may be afforded by the use of emollients, of which cod-liver oil is one of the best. Cod-liver oil and oil of cade (equal parts) is a common prescription. Chrysarobin is a powerful remedy, but has the disadvantage of soiling the clothing; moreover, on the face and scalp it is apt to produce violent dermatitis. The internal administration of arsenic in some cases is of benefit. Even after apparent recovery, there is great danger of relapse.

DR. HYDE asked whether any of these cases had the eruption on the palms of the hands.

DR. GREENOUGH replied that in none of the cases mentioned was that observed.

DR. HYDE thought that it would be well to drop the

Digitized by Google

idea that psoriasis may occur on the palms of the hands exclusively. In all the cases in which such appeared to be the case, he has been able to make another diagnosis. He has observed one or two cases of psoriasis of the head in individuals bald on the top, and in these instances the eruption confined itself to the portions covered with hair.

DR. L. A. DUHRING remarked that the reader of the paper, in referring to the diagnosis, did not allude to the difficulty sometimes experienced in diagnosticating seborrhœa capitis from psoriasis. He has found considerable trouble in the diagnosis, particularly in young girls. In these cases the eruption was confined to the scalp.

DR. A. R. ROBINSON, of New York, said, in regard to the diagnosis of favus and psoriasis, that there is usually no difficulty. He did not agree with the author in regard to one of his points of diagnosis. In the early stage of favus you do not find moisture when the crust is removed; there is a shiny appearance, and, in advanced stages, ulceration is present. He agreed with the speaker that psoriasis always occurs in small spots of hyperæmia at first, not covered with scales. He considered it primarily an affection of the rete. While it is true that psoriasis often disappears without producing pigmentation, as stated by the author, yet there may be discoloration found on the lower extremities, particularly where there is a varicose condition of the veins. In some cases where there are only a few patches of psoriasis limited to the lower extremities, it is often difficult to make the diagnosis; unless there is involvement of other parts of the body, or you have the history, it is often impossible to come to a conclusion. There are other cases, of acute psoriasis, which closely resemble acute eczema. In reference to the palms of the hands, whilst we do not see cases of psoriasis limited to this situation, yet he is sure that cases have been shown in which the palms of the hands have been affected in connection with other portions of the body.

DR. J. C. WHITE, of Boston, concurred with Dr. Duhring in regard to the difficulty of diagnosticating between psoriasis of the scalp and seborrhœa. In some cases the diagnosis cannot be made for months. In diagnosis, he does not lay much stress on the location of the eruption; when the eruption is sparse, it is more apt to affect the extensor surfaces. He should like to call attention to one termination which he has seen in three cases, as he has elsewhere given in detail, and that is a degeneration into epithelioma.

DR. R. B. MORISON, of Baltimore, said that he saw a great many cases of psoriasis in the white; but, although in dispensaries he has had many negroes under treatment, he can only recall one or two cases of psoriasis in persons of that race; in such cases there is a loss of pigment.

DR. G. H. FOX, of New York, said that too much stress is laid on the general rule that psoriasis occurs most frequently on the extensor surfaces, the knees, and the elbows. It is a notable fact that in general psoriasis the vicinity of the knee and elbow escapes. Many cases of psoriasis occur in weakly subjects; while, on the other hand, many cases appear in robust persons. In every individual case, the better the patient's health, the less likely is he to suffer from a recurrence of the affection. He has been very successful in the treatment of psoriasis, and in its management he adopts the teaching of the late Tilbury Fox. He laid stress on the point that in psoriasis, as in other inflammatory affections of the skin, and also in lupus, the first thing to do is to lessen the congestion of the skin. He does not do this by adopting the alkaline treatment, but by restricting the diet. He is somewhat indifferent as to restricting the starchy and saccharine elements of the food, but cuts off the meat, and orders a diet of fruits and vegetables in the summer, and in the winter gives a carefully restricted diet. Tea, coffee, tobacco, and stimulants of all kinds are to be cut off. By so doing, more will be accomplished than is obtained by using arsenic and local applications at the start.

In regard to local remedies, he never uses tar in the treatment of psoriasis. With the application of chrysarobin made at the proper time, there is no necessity for the use of tar. He has seen many cases in which this drug did no good, but this was because the application was made when the patches of psoriasis were in a congested condition. If the acute congestion is at first lessened, chrysarobin will produce beneficial results.

DR. C. HEITZMANN, of New York, said that one of the most important points, after making the diagnosis, is to decide as to the acuteness or chronicity of the affection. If it is acute, local applications are to be avoided; if the case is chronic, chrysarobin may be used with advantage, at least temporarily. It is not a cure. He agreed with Dr. Fox, that restriction of the diet is important for the purpose of lessening the congestion. Tar cannot be dispensed with. Chrysarobin removes the disease for a time, but in a few months it returns. There is nothing like tar to prevent the recurrence. No mention has been made of pyrogallic acid, which does good in some cases. There are, however, some cases which cannot be treated successfully with any remedies, the disease steadily growing worse.

DR. W. A. HARDAWAY believed that in psoriasis we have a disease situated in the skin itself. It is frequently hereditary. The same sort of skin may be transmitted just as a certain color of the hair or of eye may be transmitted, and then any exciting cause may develop the psoriasis. Traumatism is frequently the exciting cause. He has seen psoriasis follow eczema. It is not unlikely that seborrhœa of the scalp may lead to the development of psoriasis. Internal causes may produce it. He has seen a case in which, apparently, the excessive use of oatmeal produced typical psoriasis.

In the treatment of psoriasis, it is important to regulate the diet. He cuts off meats and aids digestion in all possible ways. As a local application, he believes that chrysarobin with salicylic acid is very useful in chronic cases. Arsenic is useful on account of its action on the skin. He has employed chrysarobin in liquor gutta-percha, and in gelatine paste. This treatment may be followed up by the application of sulphur ointment. In psoriasis of the scalp, sulphur is quite an efficient remedy.

DR. GREENOUGH said that he did not intend to cover the entire ground of psoriasis in his paper. The omission of a consideration of seborrhœa, he admitted, was an oversight. In regard to pigmentation, he referred especially to those cases of psoriasis of the trunk which were most apt to be confounded with syphilides.

Digitized by Google

DR. J. C. WHITE, of Boston, reported two

CASES OF ANGIOMA PIGMENTOSUM ET ATROPHICUM.

The first patient was a young man 17 years old, and a Russian Pole by birth. Freckles appeared on his face before he was two years of age. These increased in number until the age of six. When the telangiectasic condition first appeared was not noted. When seen, the patient was well developed and apparently in good health. He has, however, grown slowly, and is now no larger than a boy of twelve. The hair of the head is abundant and intensely black. The eyes are also black.

Present condition. Melanosis: The forehead and lower portion of the face are of a dark-brown color, and, on close inspection, small spots of a darker color are seen. The whole trunk is as dark as the skin of a dark Spaniard. The scrotum is very black, and the penis and glans present dark spots. The arms and hands are thickly spotted. The legs are also affected. On the right thigh there is one spot of dark color, covered with rather long hair. The mucous membrane of the mouth and pharynx is free from melanosis.

The atrophied condition: On the right side of the face, occupying one-half the surface, is a sharply defined area of white cicatricial looking skin. Similar areas are seen on the other cheek, forehead, and about the mouth. A few white spots are seen on other portions of the body. The sensibility of the affected areas is decidedly lessened.

Telangiectasis: Over parts of the face there are bright red spots, varying in size from a pinhead to a pea. They are most noticeable in the atrophied portions. Within the eyelids there are two angiomatous new growths. Several vascular twigs are also seen on the face. A few red points are found on the femoral surface.

The second case is a brother of Case I., aged three years, born in New York. When eighteen months old, little colored freckles were noticed on the face. Since then the condition has been increasing. His hair is dark brown and eyes are black. The face is covered with numerous dark brown freckles. The spots are so close together that at a little distance the skin has a uniform color; in some places the spots are slightly elevated; the backs of the hands are covered with dark brown spots; elsewhere the skin is clear. There are no leucodermic spots, and no angiomatous condition.

From a study of these cases, Dr. White concludes that in the beginning the development of these spots cannot be distinguished from ordinary freckles. Gradually the spots multiply until they involve a considerable portion of the skin. It is probable that several years may elapse without other manifestations of the disease. The telangiectasic condition is probably secondary. In the first case it is most developed in the atrophic portion. It is probable that in this case there will be hypertrophy of the epithelium and final transformation into epithelioma. This has been the result in the thirty-three cases which have been reported.

DR. TAYLOR thought that there was a direct relation between the red spots and the macules. The history of the cases which he has seen have been first a rash, then the red spots, and then the macules. In one case the telangiectasis followed exposure to heat.

DR. WHITE recognized a great difference in this disease as described by various writers, but he insisted on the correctness of his own observations. The younger child has exhibited none of the precedent hyperæmia which has been noted in some cases. This patient has been observed after exertion, and when exposed to intense heat, but there has been no hyperæmia. The same is true of the first case as far as known. In the second case, which is still developing, there is no enlargement of the vessels.

EVENING SESSION.

DR. J. NEVINS HYDE, of Chicago, read a paper on

THE RELATIONS OF LUPUS VULGARIS TO TUBERCULOSIS.

He began with a detailed statement of all the cases of lupus reported to the Statistical Committee of the American Dermatological Association during the last seven years, and compared the frequency of the disease in this country with that reported in the Vienna hospitals. He then gave details of twenty consecutive cases observed by him in Chicago.

The clinical deductions from these records were then added, showing, according to the author, that there was a remarkable absence of pulmonary tuberculosis, scrofula, and allied diseases in the family histories of the twenty cases reported.

The teachings of the two schools represented in the past by prominent German and French authors were then referred to, and finally the later investigations demonstrating that lupus vulgaris was the result of bacillus infection, not to be differentiated in external appearance of the parasite from the bacillus tuberculosis.

The following clinical facts were then cited in support of the later teaching of this subject as bearing on the vital point in the author's argument, viz., that lupus vulgaris is not the result, as has long been taught, of tuberculosis or other systemic diathesis, but is the product of a local infection by bacilli, entirely unassociated with any constitutional evidence of diathesis or predisposition.

1. The unimpeachable character of the family record in by far the larger number of cases of lupus vulgaris.

2. The fact that the disease is in its inception a disorder of the period of childhood, when, for the most part, the habits of the child are favorable to infection.

3. The several sites of predilection are those most favorable to such infection.

4. The failure of the disease to spread by inheritance.

5. The remarkable tendency of lupus vulgaris to cutaneous limitation.

DR. JAMES C. WHITE, of Boston, then read a paper on

THE TREATMENT OF LUPUS BY PARASITICIDES.

He reviewed briefly the evidence in favor of the parasitic nature of the affection. All previous plans of treatment which had proven most successful were those which would have the effect of destroying the parasite which might be present.

A number of cases were then reported in which the local use of corrosive sublimate in the strength of one to two grains to the ounce of water or unguent had been used with beneficial results. The ointment was especially

Digitized by Google

recommended. It had been rarely necessary to prolong treatment over two months. As regards the permanency of the cure, the author was unable to speak, as the experiments had been continued for only eighteen months.

DR. SHERWELL, of Brooklyn, expressed his profound disbelief in the parasitic nature of the disease, and he did not know that the theories of Koch have been entirely proved. It seems to him that lupus and scrofula represent forms of syphilitic hereditary influence.

DR. WIGGLESWORTH, of Boston, suggested that the oleate of mercury might be more efficient than ointments, on account of its penetrating power.

DR. HYDE said that at the last meeting of the Association, Dr. Taylor suggested the use of a solution of corrosive sublimate in tincture of benzoin for ringworm. He had used this in cases of lupus and in cases of infecting chancre. It makes an excellent application. In regard to the syphilitic origin of this affection (lupus), he said that he recognized the fact that inherited syphilis is inherited syphilis and has no relation to this or other diseases. He felt that he was standing on good ground when he said that scrofula and lupus have no relationship whatever with syphilis.

The next paper was by DR. W. A. HARDAWAY, of St. Louis, and was on

THE TREATMENT OF PORT-WINE MARK BY ELECTROLYSIS.

The author stated that in the treatment of this affection, the object is to excite sufficient inflammation to cause occlusion of the vessels. Electrolysis seems to be the most convenient way of doing this. At first the speaker had used a bundle of needles, but after the use of such, the reaction is too violent, and there is, moreover, a great tendency to keloidal development, so that he now employed only the single needle. It is important to allow a period of some weeks to elapse between the operations. The histories of three cases were given in which this method had been employed, in two of which with marked success, in the third the result was unsatisfactory.

DR. WHITE used this method in one case, and had produced considerable improvement.

DR. WIGGLESWORTH had seen good results in telangiectases from cutting the vessels in two places and using a preparation of iron, thus closing up the dilated vessels. The worst case of telangiectasis that he had ever seen occurred in a middle-aged lady whose face, in consequence of the disease, was bright red in color. He treated her for three or four years with a marvellously good result.

DR. FOX said that we all admit that spider cancers and telangiectasis are amenable to treatment of different kinds, but when we come to port-wine marks, we find a difference. He thought that better results can be obtained by electrolysis than by other measures, but it does not remove the trouble entirely. He has used the treatment with puncture and carbolic acid with fair results. In one or two cases he has passed the electrolytic needle deeply into the tissues, endeavoring to strike the artery of supply, and sometimes has produced a decided effect.

DR. DENSLOW, of St. Paul, recently saw a case of port-wine mark on the labia majora of an infant. This had ulcerated when the child was brought to him. As a temporary measure, he applied the liquor gutta-percha. In two days, without other treatment, the whole mark sloughed out, leaving nothing but a simple ulcer, which completely healed in the course of three weeks.

DR. WHITE said that the course in the case mentioned by Dr. Denslow is not an uncommon one in infants.

DR. HARDAWAY held that the advantage of the electrolysis is that it is manageable. A practical point might be referred to, and that is, if after the operation the part be frequently mopped with hot water, the inflammatory disturbance will be greatly lessened.

DR. S. SHERWELL, of Brooklyn, made some

REMARKS ON A MOOTED POINT IN THE ETIOLOGY OF PSORIASIS.

He had been struck by the great diversity of opinion in regard to the general health of those affected with psoriasis, and, in order to arrive at something like a consensus of opinion on the subject, he had referred to the writings of most of the authorities in dermatological matters. Brief extracts from various writers were then given. The evidence thus obtained strengthened the Doctor's opinion that patients with psoriasis are generally in good health. He thought that the theory of Piffard, who believes that the rheumatic diathesis is a great exciting cause of psoriasis, was the most rational theory that had been advanced.

THURSDAY, AUGUST 27TH.

MORNING SESSION.

At the Business Meeting, the following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. E. Wigglesworth, of Boston.

Vice-Presidents.—Dr. I. E. Atkinson, of Baltimore, and Dr. A. R. Robinson, of New York.

Secretary.—Dr. G. H. Tilden, of Boston.

Treasurer.—Dr. H. W. Stelwagon, of Philadelphia.

Dr. F. B. Bronson, of New York, was elected to membership.

The next meeting will be held, beginning on the last Wednesday of August, 1886, at Indian Harbor Hotel, Greenwich, Conn.

The Committee on Statistics made a brief report.

DR. G. H. FOX gave a brief description of

TWO CASES OF DYSIDROSIS.

The first case, for want of a better term, he classed under this heading. The patient was twenty-nine years of age, and had always perspired freely. Four years ago the eruption began on the palms of the hand, and had persisted. The soles of the feet had also been affected at one time. The skin of the hands was decidedly thick and had a dark hue, and was dotted with numerous elevations of epidermis, averaging in size that of a hemp-seed. The patient had never seen any moisture in connection with the disease. There had been no itching. The skin never peeled off. Puncture with a needle revealed no serum or fluid of any kind.

The second case was that of a woman aged 46, a cook, whose general health was good. The present trouble began five years ago. The eruption is on the face and consists of numerous large and small vesicles containing clear fluid.

Digitized by Google

DR. ROBINSON said that these latter cases are not infrequent and may persist for months and years. They consist in destruction of the sweat ducts in the chorion. They never become inflammatory, although sometimes they may be surrounded by a little areola as the result of pressure. The symptoms which they present do not at all correspond to those of dysidrosis as described by Hutchinson and Tilbury Fox, as belonging to dysidrosis of the palms.

DR. STELWAGON said that, judging from his own experience of the past several years, the affection, as described in Dr. Fox's second case, is not at all uncommon, observed especially in washerwomen and cooks. At first he was unable to classify the disease, resembling as it does dysidrosis, but has lately looked upon the affection as sudamen. The only description of the disease that he has been able to find occurs under the head of that disease in Dr. Robinson's treatise on skin diseases.

DR. A. R. ROBINSON, of New York, presented a paper on

MYCOLOGICAL STUDIES IN TINEA FAVOSA AND TINEA TRICOPHYTINA.

The epidermis of different individuals, he said, differs in susceptibility to these parasites. Children are more apt to suffer with tinea tricophytina and favus, while adults more frequently presented tinea versicolor. All children are not equally susceptible. In many cases of parasitic disease there is impaired vitality previous to the development of the affection.

He then gave an account of his investigations to determine the exact anatomical seat of the parasitic diseases in question and to determine the changes which they produced in surrounding tissues. The conclusion was that in favus the rete is not affected until the later stages, when as a result of pressure the rete and corium are atrophied or ulcerated. The parasite confines itself more particularly to the corneous layer. The parasite of tinea tricophytina in some cases passes down into the rete, while in others it does not.

A number of sections were shown under the microscope which illustrated the points brought out in the paper.

DR. WHITE asked what evidence there was that in ringworm and favus a decreased vitality is necessary.

DR. ROBINSON thought that it was found in the fact that it is exceedingly difficult to cure these affections occurring in broken-down subjects, until the general health is improved.

DR. WHITE asked if there is any evidence that the fungus attaches itself more readily, or runs a more rapid course in unhealthy children?

DR. ROBINSON replied that practical experience shows that it is well known that in hospitals the disease will spread more rapidly than in private families.

DR. WHITE could not agree with the speaker in the importance of depressed general health as a factor in the production of these diseases. He has never seen any necessity for internal treatment in these cases. Where the disease affects a superficial portion of the body it is readily removed, but where it involves a portion covered with hair it is difficult to cure. Although he thinks the improvement of the general condition has nothing to do with the cure of the parasitic trouble, yet it is of service in the restoration of the parts to their natural condition after the parasite has been destroyed.

DR. PIFFARD, of New York, agreed with Dr. Robinson that there is a relation between the condition of the general system and the rapidity of development and rapidity of cure.

DR. DUHRING has always held the view that a peculiar condition of the epidermis was necessary for the growth of the fungus. The majority of cases of obstinate ringworm that he has seen, have been in individuals in poor health, but there are exceptions to this rule. What this peculiar condition of the skin is, has not been determined.

DR. HEITZMANN said that as regards the constitution of the patient, he must agree with Dr. White. He had seen in the Vienna clinic strong healthy persons covered from head to foot with tinea.

DR. DENSLOW had recently seen a large number of cases of ringworm of the head and beard, but all the patients were well-developed muscular subjects. These were cured without internal treatment.

DR. HEITZMANN, of New York, then read a paper on

THE STRUCTURE OF THE DERMA AND THE DEVELOPMENT OF ELASTIC TISSUE IN IT.

He based upon his orignal investigation a claim that the bundles which compose the derma by freely interlacing, are not made up of fibres, but of dense, delicate spindles, representing the basis-substance. Between the spindles is a chemically different cement-substance. The interstices between the bundles are occupied by protoplasm, everywhere connected and nowhere in the shape of the so-called connective-tissue cells. According to the general spindle-shaped configuration of the bundles the protoplasmic cords produce a comparatively coarse reticulum, freely supplied with nuclei. In connection with the protoplasm there is a delicate reticulum of living matter, piercing both the basis- and the cement-substance. The non-living portions are very minute, while the main bulk of the derma has all properties of life, as shown by feeding kids with milk and grass, which latter very rapidly alters the density of the derma. In inflammation not only the protoplasm participates in an active manner by new formation of inflammatory corpuscles, but the whole basis-substance breaks apart into such corpuscles. With advancing age the protoplasm becomes less, being transformed into basis-substance, the bulk of which is augmented. At the meeting-edges of the bundles the protoplasm is transformed into elastic substance, the third variety of basis-substance in the derma. Still the branching elastic ledges remain, traversed by delicate offshoots of living matter. In this view the best microscopist of Europe, Prof. Stricker, of Vienna, coincides with the speaker.

DR. W. A. HARDAWAY described

A CASE OF MULTIPLE MYOMATA OF THE SKIN, ACCOMPANIED BY SEVERE PAIN.

A. B., age, 36, married, with healthy children and good family history. Never had syphilis. Present trouble began a year ago. Changes in weather produced pains in the parts which have since become affected; to relieve these firm pressure was made with the hand. Later the lesions presented themselves.

Present condition: A strong hearty man, a peddler

Digitized by Google

by occupation. The pains still persist, recurring at intervals of one night to a week. Each attack lasts two or three minutes and does not return the same night.

The growth is situated on the right side of the back in the middorsal region, and the course of the growths is obliquely outwards. There are one or two elevations on the left side, three of the growths are as large as peas, others are small. The epidermis is not abnormal. On passing the hand over these growths there is no hyperæsthesia, but on deep pressure in the neighborhood of the larger masses the patient sinks moaning to the floor. One of the larger growths was removed and microscopical examination showed it to be composed of smooth muscular fibre.

From a clinical standpoint, the case bears a close relation to the cases of neuroma which have been reported. The speaker concluded that certain new growths in the skin accompanied with severe pain may be widely different in histological structure. We are not justified in assuming, that a painful tumor of the skin is a neuroma or fibro-neuroma simply from its clinical history, without a microscopical examination.

DR. DUHRING said that it would be difficult to differentiate from the local appearances, the case described by Dr. Hardaway and that which he reported some years ago. It is not possible from a clinical standpoint, as has been said, to differentiate these growths; we are obliged to rely on the microscope. There is one point of difference in his case and that just described: no pain was produced by superficial manipulations, while in his case the pain was intense on the slightest touch, while firm pressure decreased the pain.

DR. R. B. MORISON, of Baltimore, reported

AN UNUSUAL CASE OF TYLOSIS OF THE HANDS.

The patient was a negro, aged 32, muscular, well developed, and apparently healthy. By occupation he was a fireman of a steamer, and had occupied this position for ten years, shovelling coal, with the right hand grasping the upper portion of the shovel, and the left hand sliding up and down the handle. Two fingers of the left hand are worn off to the second joint, while the other two are going in the same way, the nails having disappeared. On several occasions he has drawn pieces of bone from the fingers. There has been no pain at all connected with the affection. On this hand there are some large blisters, underneath which there are red granulating surfaces, which are painless. There is no history nor evidence of syphilis. Specific treatment has been used without effect. The man obstinately refuses to give up his work so that little could be done in the way of treatment.

DR. WHITE said that from the unusual result, it would seem that there must have been some precedent change causing atrophy.

DR. TILDEN remarked that there is a good deal of resemblance between this case and the cases of perforating ulcer of the foot, and this would lead us to suspect a nervous element.

DR. WIGGLESWORTH said that this resembles in some respects anæsthetic leprosy, but it differs in other points.

DR. MORISON was led to consider it a strictly local affection, from the fact that the hand which was most exposed to rubbing and to the heat of the furnace, was the one most affected.

DR. DUHRING should be inclined to consider the callosities a secondary condition. The occupation probably had something to do with the aggravation of the disease. But if the occupation had been different, there would probably have been a similar change. He should regard it as dependent on some deep change in connection with the nerves, similar to that occurring in perforating ulcer of the foot.

DR. MORISON said that it was an affection of the nerve in the first place he can hardly admit. It may be that the continued congestion of the skin, dependent on his occupation, produced changes in the nerves or other part, which culminated in this affection. In referring to the literature of the subject, he found similar cases attributed to mechanical irritation.

NEWS ITEMS.

THE REPORT OF THE ACADEMY OF MEDICINE OF MADRID ON DR. FERRÁN'S SYSTEM.—The Sanitary Commission of Germany having recently pronounced against the system of inoculation practised by Dr. Ferrán, the decision of the Academy of Medicine of Madrid with reference to the same, is a matter of interest. Subjoined is the text of their conclusions.

The Academy agrees with the Commission which went to Valencia to investigate Ferrán's methods:

1. That the epidemic which commenced in the eastern provinces, and which afterwards extended to other provinces, is positively Asiatic cholera.

2. With respect to the controversy whether the epidemic is more contagious than infectious, as the Commission affirmed, or if it be infectious and not contagious, as mentioned by Señor Don Martin, in his separate note, the Academy limits itself to the statement that the illness of which it treats is transmissible from the infected points to healthy ones.

3. The Academy agrees also that the inoculation material used by Ferrán contains comma-bacilli, but adds also that the strength of the inoculation material varies with its preparation, *i. e.*, an equal quantity of the fluid may contain a greater or less number of bacilli.

4. The Academy cannot admit without restriction that inoculation is inoffensive, as affirmed by the Commission; for it is impossible to say that, supposing an artificial cholera be produced, it shall not cause some risk to places not attacked, and on account of individual idiosyncrasy, decomposition of the fluids used, or from other causes, not result in the injury of the inoculated individuals.

5. The Academy not having any exact and reliable statistics, is unable to report concerning the efficacy of the process.

6. The Academy agrees with the Commission, that no sufficient reasons exist to lead them to oppose inoculations under the responsibility of Dr. Ferrán, and believes that it is well to inform the public of the doubtfulness of the scientific nature of the inoculations, and of the possible effects of the inoculation upon those who submit to it.

7. The Academy neither defends nor recommends the procedure, as long as its method is kept secret or experience does not prove its efficacy.—*Wiener med. Presse*, Aug. 9, 1885.

DR. HENRY B. SANDS has resigned the professorship of the Practice of Surgery at the College of Physicians and Surgeons. He will, however, continue his clinical work in connection with the institution.

MORE RESIGNATIONS FROM THE CONGRESS.—Dr. Alfred L. Carroll, of Albany, has declined the Vice-Presidency of the Section of Public and International Hygiene, Dr. Delavan Bloodgood, U. S. N., has declined the position of Councillor in the Section of Military and Naval Surgery and Medicine, and Dr. R. P. Lincoln, of New York, of Councillor in the Section of Laryngology.

THE SPECIAL MEETING OF THE CONGRESS COMMITTEE.—It is to be presumed that the meeting will undertake little else than the repair of damages—that is, the appointing of others to take the places of the distinguished men who have declined to take part in the present organization. That any such action will fail of its purpose seems to us unquestionable. We do not doubt, indeed, that men enough can be found who will be willing and even glad to hold official positions in a gathering that will be international only in name. But, allowing that the Committee made the best choice it could have made at Chicago, any selections that it makes now must necessarily be of inferior men, and it is doubtful even if men a grade below those first chosen would be willing to figure before the world as the recipients of appointments that had gone begging. It can scarcely be doubted, therefore, that the corps of appointees will be largely inferior to the remnants left by the recent defections. Far from having been mended, matters will then have been made worse; but, if this is to be the result, it is best that it should come promptly, that the remedy may follow the more speedily.—*New York Medical Journal.*

THE PRICE OF COCAINE.—Dr. Squibb, in *Ephemeris*, for July, 1885, in discussing the price of this hitherto high-priced drug, says:

If the cost of the process of extraction be a little over five cents a grain, the vial, label, and overweight in putting up would probably bring the cost up to six cents per grain, or a little more. Such articles are not worth making unless the profit upon them be liberal, especially until the losses in acquiring a good process be fully compensated; therefore, the salt should now bring at least ten cents per grain under the present very favorable conditions.

Under these conditions of market the writer, about June 15th, decided to reduce his price for hydrochlorate of cocaine, on July 1st, to ten cents per grain, thus getting it at once down to as low a price as it will be likely to reach in his hands, so long as the heavy tax of this country applies to alcohol and ether, and no less expensive solvents are applied.

This price, however, will certainly be low enough to enable the uses of the substance to be greatly extended.

NOTES AND QUERIES.

CASE OF PROLONGED GESTATION.

To the Editor of THE MEDICAL NEWS.

HEALTH DEPARTMENT, CITY HALL, Aug. 28, 1885.

SIR: I inclose copy (leaving out the names of parties) of a "return of a birth," received yesterday from one of our most respectable physicians, also give you a copy of his note appended, thinking it may prove of interest to some of the readers of your valuable journal, as it is certainly a very remarkable case, if all the statements are correct, and I have no reason at all to doubt them.

Very respectfully,

A. MARKS, Secretary.

RETURN OF A BIRTH TO THE OFFICE OF REGISTRAR OF VITAL STATISTICS, BOARD OF HEALTH, BALTIMORE CITY.

No. of child of mother (state whether first, second, third, etc.). Fifth.
1. Sex (state whether male or female). Female.
2. Race or color (if not of the white race). White.
3. Date of birth. Aug. 25, 1885.
4. Place of birth (street and number). 437 N. Calhoun St.
5. Full name of mother. Mary E. M.
6. Mother's maiden name. Mary E. P.
7. Mother's birthplace. Baltimore.
8. Full name of father. A. H. M.
9. Father's occupation. Trader.
10. Father's birthplace. Baltimore.

Name of medical attendant (or other person who makes this return). E. W. F., M.D.

Address. 192 N. Casey St.

Remarks.—"This is a very strange case. The mother says she has felt the movements of the child for over nine months, and has not menstruated for fourteen months." (See note appended.)

(Copy of Note.)

"Mrs. M., the mother of the child mentioned in this certificate, claims that she has felt the motion of the child for over nine months, and that she has not menstruated for fourteen months. She has been in a very critical condition for the past four months, and quite dropsical, thus obscuring her actual condition, and rendering a correct diagnosis very difficult. She was seen by quite a number of physicians, and was once taken to the Infirmary without any definite conclusion as to her condition.

"The mother of Mrs. M. confirms the statement of the daughter. The child is large (15¼ lbs.). Bones of the head firmly united at the sutures, and has the appearance of a child several months old, lifting its hand and looking around while being washed. Perhaps when I call next time I may find it toddling round the room.

"E. W. F."

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 25, 1885, TO AUGUST 31, 1885.

CRONKITE, H. M., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Reno, Indian Territory, and assigned to duty as Post Surgeon, Fort Hays, Kansas.—*S. O. 129, Department of the Missouri*, August 26, 1885.

DAVIS, WM. B., *Captain and Assistant Surgeon.*—Having reported for orders from leave of absence, assigned to duty at Fort Porter, N. Y., as Post Surgeon.—*S. O. 183, Department of the East*, August 28, 1885.

POWELL, J. S., *Captain and Assistant Surgeon.*—Relieved from temporary duty at Fort Leavenworth, Kansas, and assigned to duty as Post Surgeon at Fort Lyon, Colorado.—*S. O. 128, Department of the Missouri*, August 25, 1885.

KANE, JOHN J., *Captain and Assistant Surgeon.*—Granted leave of absence for one month, to take effect when his services can be spared.—*S. O. 195, A. G. O.*, August 26, 1885.

EBERT, R. G. *Captain and Assistant Surgeon.*—Assigned to temporary duty with U. S. troops at Riverside Park, N. Y.—*S. O. 179, Department of the East*, August 24, 1885.

MCCAW, W. D., *First Lieutenant and Assistant Surgeon.*—Assigned to temporary duty at the camp of the troops near Kiowa, Kansas.—*S. O. 128, Department of the Missouri*, Aug. 25, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING AUGUST 29, 1885.

WM. H. JONES, *Surgeon.*—Detached from the Wachusett, and waiting orders.

VOL. XLVII. SATURDAY, SEPTEMBER 12, 1885. NO. 11.

ORIGINAL ARTICLES.

A SERIES OF ONE HUNDRED AND TWELVE CONSECUTIVE OPERATIONS FOR OVARIAN AND PAROVARIAN CYSTOMA WITHOUT A DEATH.

BY LAWSON TAIT, F.R.C.S. ENG.

I HAVE already published a detailed statement of all my operations up to the end of December, 1883, and I bring forward the present series up to the 7th August, 1885, chiefly for the purpose of disposing, finally and for ever, so far as I am concerned, of the much-discussed question of Listerism in abdominal surgery. As I have repeatedly said in former publications, I tried the so-called antiseptic system in all its ever-varying details in as complete and unprejudiced a series of experiments as I believe it possible for man to undertake. I finally came to the conclusion that my patients were being poisoned by the use of carbolic acid, thymol, and various other chemical substances, which were being used by others as well as myself for the purpose of destroying the germs which were supposed to do so much harm. I published a series of cases which proved to my mind conclusively that I could do better without Listerism than with it, that in fact the only tendency of this so-called antiseptic system was to mar a success which was speedily increasing, and which arose from a variety of improvements, at the head of which was the discontinuance of the clamp.

In the practice of Sir Spencer Wells the introduction of Listerism and the introduction of the intraperitoneal method of dealing with the pedicle occurred almost at the same time, and it is not surprising that he should attribute his much-diminished mortality to Listerism rather than confess that he had retarded the advance of abdominal surgery for nearly a quarter of a century by his disregard of the lessons taught by Nathan Smith, Charles Clay, and Baker Browne.

Against my own conclusions there has been advanced more than once the argument that Dr. Keith had a long series of consecutive cases, seventy-two in number, whilst using Listerian methods. I now meet that argument by a still longer series of 112 consecutive cases, in not one of which has carbolic acid, or thymol, or corrosive sublimate, or any of the multifarious germicides, touched my patients either directly or indirectly. So far as I know, the present series has never been approached in its success, and as I have steadily reduced my mortality since I gave up the clamp from eight per cent. to six, five, and three per cent., till I have, as I may almost say, brought it to a vanishing point, I think my conclusions in previous papers are completely established. These conclusions were, in the main, that the great elements of my growing success were increased personal experience, increased attention to all the minute details which go to create success, and inattention to any one of which may defeat the best-laid plans. In addition to these, I may add scrupulous attention to cleanliness and an undeviating enforcement of discipline, both on the part of the patients and my staff of assistants.

The present series may be analyzed as follows:

Dermoid cyst	1
Cystic sarcoma	1
Abscess of ovary	2
Cystoma of one ovary	49
Cystoma of both ovaries	38
Parovarian cysts	21

Of this analysis very little need be said, except that it completely confirms my previous statement that removal of both ovaries for cystoma is not in any way a more serious operation than removal of one. It will be remembered that Sir Spencer Wells has always insisted that the contrary was the case, and it certainly was so in the cases where he used the clamp, another of the many arguments that the clamp, and that alone, was the cause of his tremendous mortality. In these eighty-nine cases of ovarian cystoma every kind of difficulty has been met with. The tumors have been in many instances of enormous size, and every variety and extent of adhesion has occurred; but neither size, nor extent, nor nature of adhesion seems now to make the slightest difference in the results of the operation. In every case where there has been a tendency to ooze, or where the patient has been advanced in life, I have used the drainage-tube, an addition to our means of saving life of which it is impossible to speak too highly. In every case but two the Staffordshire knot has been the means used for securing the pedicle, and here again is an improvement to which my success must be largely attributed: it never slips: I have had no trouble with secondary hemorrhage, and there have been no subsequent suppurations in the pelvis. In the two cases where the Staffordshire knot was not used, no kind of method of securing the pedicle was found to be of any avail, except securing it by a number of pressure-forceps, and leaving them in the pelvis, protruding through the wound for some forty hours after the operation, when they were cautiously removed one by one.

Of the parovarian cysts I can only say that the removal of many of them presented perfect simplicity in every detail, whilst the removal of others might be reckoned amongst the most ghastly and serious operations with which anyone could meet. The main difficulty in these operations consists of this, that the cysts having lifted the structures in the broad ligament bodily out of the pelvis, the tumors therefore not only present no pedicle, but present no free surface of any kind, and they have to be dealt with entirely by the method of enucleation originally devised by Dr. Miner. These cases, until 1876, would all have

been recorded as incomplete operations, for what used to be done both by myself and by others was to remove about a quarter of the cyst and stitch the stump to the wound, trusting to it healing by suppuration and granulation. But to my sorrow I found that these cases did not heal, that they went on suppurating for months and years, and finally died. Now I completely enucleate the cysts, regardless of the extent or nature of adhesions, and have done so without failure in any instance, taking the cyst out of the pelvis from intimate association with every organ in it. The operations are tedious and difficult, and the bleeding is sometimes most profuse, but sponge packing, and occasional touch of the cautery, and the drainage-tube, have given me success in every instance. The cavities in which the tumors were set have all completely healed, and not a single sinus remains in any of my patients.

Parovarian cysts have a peculiar tendency to rotate on their axis, and to become strangulated and gangrenous. This complication leads to acute peritonitis, and the patients, if not relieved by immediate operation, die. In the present series there have been ten cases of these rotated and gangrenous tumors, and without a single exception they have grown from the right side and have been rotated from the left side forwards into the right. This completely establishes the theoretical explanation of the axial rotation of ovarian and parovarian tumors, which I advanced in 1880 in a paper read before the Obstetrical Society. So extensive now has been my experience of this peculiar complication, that in one case (94) I actually made the diagnosis without seeing the patient under the following circumstances. Feeling rather out of sorts one evening I had gone to bed unusually early, and after having retired I was aroused by my friend Dr. Parkes, who came to tell me of a case in which he wanted my assistance and of which he gave me the following brief history. The patient had been confined about three weeks before and had made a perfectly easy and rapid recovery, but about fourteen days after her confinement she drew Dr. Parkes's attention to a lump just above the pelvis, and this he thought was the uterus in a condition of subinvolution, and regarded it as of no moment; but, very much to his surprise, in three or four days it was very much larger, and on the morning of his seeking my assistance the patient was suddenly attacked by violent pain, and he found the tumor as big as an adult's head above the brim of the pelvis. I told him that there could be no doubt that it was an instance of an ovarian tumor growing with great rapidity after confinement, as I had seen occur in many instances, and that it had rotated on its axis and was becoming gangrenous. I agreed to see the patient with him the next morning early. The acute symptoms had somewhat subsided by the time I saw her, but the tumor, Dr. Parkes assured me, was quite one-third larger than it had been the previous day. There could be no doubt that the diagnosis which I had given the preceding evening was the correct one, and we at once removed the patient from her home to my private hospital. I opened the abdomen within three hours of her arrival, and found the tumor to be the right ovary with a pedicle twisted nearly three revolutions, the tumor quite black and semi-gangrenous, and the contents of its cavity consisting of at least three parts blood.

Of the subsequent history of these patients, remarks need only be made upon two. One (76) was an old lady aged seventy, from whom I removed a rapidly growing tumor of immense size. I had a suspicion

Digitized by Google

at the time of the operation that there was something more the matter with her than the tumor, and although she made a wonderful convalescence considering her advanced age, and got about for some time after the operation, she died suddenly shortly after her return home, without any symptoms which could be definitely referred to a specific ailment. After death she was found to be suffering from an abscess of the liver. The other (41) is now suffering from general papilloma of the peritoneum, has become dropsical, and of course will die in the course of a few months.

Only one other point requires notice, and that is, that during the time occupied by the performance of this series—that is, from the 1st January, 1884, to the 7th August, 1885—I have not left incomplete any operation begun for ovarian or parovarian cystoma, and this is to me the most satisfactory fact in the history of the series.

AN OPERATION WITH A DOUBLE NEEDLE, OR BIDENT, FOR THE REMOVAL OF A CRYSTALLINE LENS DISLOCATED INTO THE VITREOUS CHAMBER.

BY CORNELIUS R. AGNEW, M.D.,

CLINICAL PROFESSOR OF DISEASES OF EYE AND EAR IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

To remove a dislocated lens from the anterior chamber of the eye is difficult, and to remove one from the vitreous chamber and save the integrity of the organ is perilous, and more difficult than any other operation in ophthalmic surgery. Excellent authorities therefore agree in recommending, in many cases, the practice of enucleation rather than to incur the immediate and later risks of attempted removal of dislocated crystalline lenses.

In numerous cases of dislocated lens the aqueous and vitreous humors are altered in their physical condition, being commingled or degenerated. When that is so, the instant that an opening is made for introducing a scoop, or other instrument, to extract the misplaced and mobile lens, there is a quick loss of the fluid contents of the eye. The eye wall falls in, the cornea crumples, and the lens eluding the instrument used for its removal, sinks into the vitreous chamber. If detachment of the retina or choroid with hemorrhage does not immediately occur, great violence is done by the operator in prodding after the lens. If the lens be finally extracted, secondary consequences occur, which cause the wounded eye to be very irritable and prone to become the focus of sympathetic trouble for the fellow eye. To avoid so direful a sequel, cautious operators have preferred to enucleate the eyeball in which there is a misplaced lens, instead of attempting to extract. This conclusion, reached by so many, has no doubt been furthered by the difficulties attending the fixation and subsequent extraction of the dislocated lens with the least loss of the fluid contents of the eye, and with the least traumatism.

Having had many cases of dislocated lens in the thirty years of my public and private work, I had come to look upon them as very embarrassing. I had also had occasion to know from actual trial, and with a fair amount of dexterity, the difficulties attending all the proposed methods for the removal of the offending body. Considering the alternative of enucleation, I could not help remembering that, easy as the mechanical part of that procedure is for the merest tyro in ophthalmic surgery, it is not without grave drawbacks for its subjects. A quiet, sightless eyeball, unless so enlarged as to be monstrous and a conspicuous deformity, is far better than the best fitting artificial eye. Furthermore, the history of the sockets left by entire enucleation is not, by any means, one of unbroken satisfaction. Enucleation is always a serious mutilation, and, like an amputation, should never be done if any other less radical procedure is practicable and prudent. I cautiously dissent from the doctrine, that, inasmuch as danger to a fellow eye may possibly occur at a more or less remote epoch in cases supposed to resemble those in which sympathetic trouble has been known to happen, therefore, we should always enucleate in a case in which sympathetic disease *may* possibly result. A considerable, and probably an increasing, number of cases in which sympathetic disease is not present, may be safely treated upon the expectant plan, or by surgical procedures in which less than the entire eyeball is sacrificed.

Believing that the impossibility of removing dislocated lenses, in some cases, without inflicting upon the eye destructive violence, had induced surgeons to resort to enucleation, it occurred to me to attempt so to modify the existing methods as to lessen what seemed to me to be the greatest difficulty, namely, to secure fixation of the lens in an accessible place, till a corneal wound had been made sufficient for its removal; and, in addition, to use the lens by means of the instrument of fixation, so as to plug the pupil more or less closely and retard the efflux of the fluids of the eye to as late a moment as possible in the manœuvre. If this is attempted by the use of a single needle, it may not be possible to raise the lens, if it be submerged in the vitreous humor. If it be raised, it may not be possible to prevent its falling over the needle and becoming again submerged, thus provoking the operator to dip his instrument again and again in the depths of the eye, to the injury of the tissues through which it penetrates or is swept. If the single needle is so used as to lift the lens and hold it near enough to the anterior chamber to be easily accessible after corneal section, its handle must be intrusted to an assistant, and thus it happens that two operators are acting in some of the steps of the operation without the indispensable benefit of accurate and unfailing coöperation. It is much better in those surgical manœuvres in which the quality of the result must depend greatly upon the harmony of consecutive steps that one will should be in control. This rule holds, however skilful and accordant the assistant may be.

Influenced, then, by the two foregoing considerations, among others, I devised the double needle, or bident, which is shown in the illustrations which accompany the narrative of the following case.

I. M., æt. 27, has been blind in his right eye from earliest infancy. The form and general appearance of the exterior of the organ are normal. Its iris is

Digitized by Google

tremulous, the pupil contractile, and somewhat more dilated than that of the fellow eye. Its crystalline lens is of full size, or nearly so, opaque and mottled, as from beginning calcific degeneration. The lens is also so loose that it moves to and fro with a quick, volatile motion, though suspended, on the temporal side, by a narrow, hinge-like attachment of the suspensory ligament. When the patient throws his head back the lens is snatched out of the direct view of the observer, but may be seen by oblique inspection in the temporo-ciliary region. The eye is sometimes irritable, but seldom, if ever, reddened, and there is constantly present a sense of something in motion in the eye.

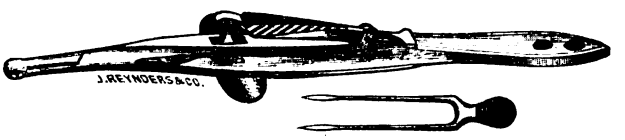
The patient is painfully conscious of the startling deformity which the perpetual appearance and disappearance of the white lens in a dark pupil produces on every motion of the eye and head. For some time the fellow eye has also engaged his attention, partly because its endurance seemed to be lessened, and partly because apprehension has arisen lest sympathetic disease might make an insidious invasion. Although, for many years intolerant of the idea of any operative interference, he has at last become convinced that he cannot much longer endure the irksomeness of his condition, and the dangers which threaten the faulty organ. The vision of his well eye is $\frac{20}{15}$, that of the fellow eye = o.

Several surgeons had examined the case, and more recently, at my suggestion, he sought the advice of a most eminent colleague in New York. The latter advised that the troublesome eye should be enucleated, instead of any attempt being made to remove the dislocated lens. In this the patient would not acquiesce. He therefore went to his home, in a distant city, but almost immediately returned again to New York, as the eye seemed to be worse, and sympathy in its fellow more noticeable.

After explaining that my attempts to remove the lens might fail, and that it might be expedient, during the course of such an operation, to resort to immediate enucleation, the patient left the matter entirely in my hands.

Believing that the ordinary methods for the removal of a lens dislocated into the vitreous humor would fail, I devised the procedure which is now offered for consideration. I dilated the pupil with atropia, but could not produce as wide dilatation as might have been expected in a normal eye. I then placed the patient on his back in charge of the following medical colleagues: Drs. Webster, Coleman, Beard, and Ring, requesting them to keep his head as immovable as possible, to avoid the complete detachment of the lens. We then gave ether as thoroughly as possible. Observing that the eye retained some sensibility even after the breathing of the patient had become stertorous, and wishing to have analgesia of the organ, we instilled a few drops of four per cent. solution of hydrochlorate of cocaine upon the conjunctival surface. I next opened the eyelids with a Gräfe's speculum, and fixed the eye by grasping the tissues between the insertion of the inferior rectus and the margin of the cornea with ordinary fixation forceps. Looking in through the pupil we could just discern the dislocated lens lying far to the temporal side of the vitreous chamber in the ciliary region. I now brought into use the little appliance with which we hoped to facilitate the removal of the lens. The instrument, with its handle, a Sands's needle-holder, is delineated in the first illustration.

FIG. 1.



It consists of two ordinary, fine, straight, delicately pointed, cataract needles, about six-eighths of an inch long, fixed parallel at a distance a little less than an eighth of an inch apart. These needles are united at their proximal ends by a projection which is flat, and otherwise so shaped and roughened as to be adapted to the grasp of the beak of a holder, such as that known in the shops as Sands's needle-holder. Although averse to laying any claim whatever as an inventor of new instruments, I may, perhaps, venture to call the needles a bident.

Having mounted the bident in the holder with the thumb catch of the latter uppermost, and having the eyeball firmly fixed as previously stated, I penetrated the temporal aspect of the eyeball at a point just far enough back to enter the vitreous chamber without wounding the iris, or touching the dislocated lens, till the bident had penetrated the vitreous humor to a point a little to the temporal side of its centre. I then, by depressing the handle of the holder, caused the points of the bident to describe an arc forwards. I was greatly pleased to see the lens caught on the bident—as a pea might be lifted on a two-tine fork, and brought forward through the pupil into the anterior chamber. I then pushed the bident on and caused its points to emerge on the nasal side of the eyeball close behind, but avoiding the iris.

The neat completion of the wound of exit was insured by placing the end of the forefinger of my left hand upon the surface of the eyeball at the point to which I was directing the bident. In this manner the scleral conjunctiva being pressed upon the points of the bident they were passed so quickly through the subconjunctival space after penetrating the sclerotic as not to let any fluid flow into and distend the subconjunctival connective tissue. The holder was then detached from the bident, and the lens remained free upon its prongs and pressed against the cornea, as shown in the second illustration.

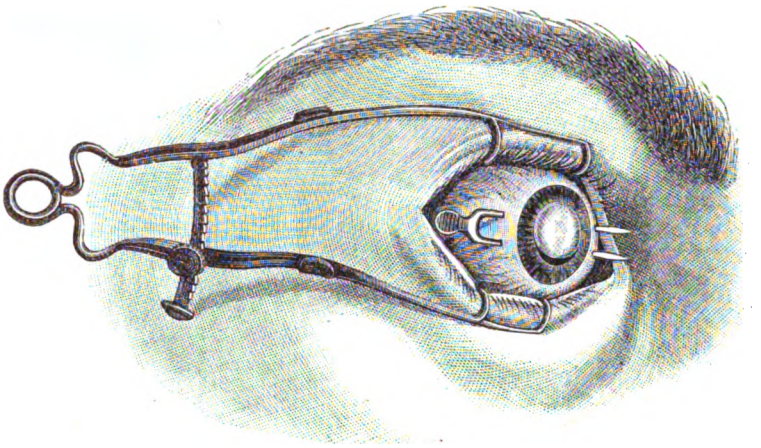
With a narrow Gräfe's knife I then made a sufficient wound in a downward direction in the cornea, and easily completed the delivery of the lens with a delicate wire or skeleton spoon. Under similar circumstances I might probably deliver the lens by a partial withdrawal of the bident and dispense with the use of the spoon.

I then removed the bident with the holder. Although this was done without difficulty, I would prefer, under similar circumstances, to do it with my thumb and forefinger, as being quite easy, and thus avoiding the necessity of applying the holder a second time. Not applying the holder would cut

Digitized by Google

off one movement from the manœuvre. There was scarcely any appreciable escape of fluid, as the lens seemed to plug the pupil, and on its delivery the bident was instantly removed. The corneal wound fell into neat coaptation, and there was no prolapse of iris.

FIG. 2.



I then closed both eyes, greased the surface of the eyelids with white vaseline, applied light compresses of absorbent cotton, a thin flannel bandage, and over all a black silk mask. The patient was placed in bed on his back, and much motion and all forms of excitement forbidden.

For two days the dressings were not removed. At the end of that time they were removed, the entire surface of the eyelids washed with warm solution of hydrarg. bichloride, one to two thousand, and some of the same solution allowed to penetrate the palpebral slit. As the eye was somewhat painful and reddened, a drop or two of a two per cent. solution of sulphate of atropia and of a four per cent. solution of hydrochlorate of cocaine was also instilled, and the dressings reapplied. Such was the course pursued.

The recovery was continuous and uneventful. The operation was done November 13, 1884, and the cure was complete December 1, 1884. The pupil remained responsive to light. It had become a little drawn in the direction of the corneal wound, though contractile and not adherent.

As the eye had been quite blind from infancy, no vision was expected after the operation. Subsequent ophthalmoscopic examination revealed extensive plaques of old choroidal and retinal atrophy, with complete atrophy of the optic nerve, lesions antecedent to or soon following birth.

January, 1885.—Patient has been again under observation for an affection of the ear. The eye is well, and the result in every way satisfactory to the patient, to my friend, Dr. Webster, and to myself.

It may be said that the lens might have been removed by using a large spoon through a section of the cornea with or without iridectomy. That with other methods was considered and dismissed as impracticable. I had had the case under observation for more than seven years, and studied it in the light of every known surgical procedure. I do not think I could have met the indications with any of the methods previously in use.

That the method is applicable to all cases of dislocated lens, especially those in which the lens is in the anterior chamber, I do not claim. It is even possible that it may be relegated, after further trial, to the list of the curiosities of ophthalmic surgery. The method of inserting a single needle, or a bident, by means of a detachable needle-holder, may prove of value in certain cases of foreign body in the chambers of the eye. I recall cases of other foreign bodies than dislocated lenses, in which I would have got valuable aid from it.

SULPHITES.

BY GEORGE M. STERNBERG, M.D.,
SURGEON U. S. ARMY.

SODIUM SULPHITE AND SODIUM HYPOSULPHITE.

MY experiments made at San Francisco (*American Journal of the Medical Sciences*, April, 1883) show that these salts in concentrated solution have no germicide power. The micrococcus of pus was not killed by exposure for two hours to a thirty-two per cent. solution, and a saturated solution failed to destroy the bacteria in broken-down beef-tea. Arloing, Cornevin, and Thomas found that exposure for forty-eight hours to a fifty per cent. solution of sodium hyposulphite does not destroy the virus of symptomatic anthrax. It is evident, from the experimental evidence on record, that these salts have no value, either as germicides or as antiseptics, *except in the presence of some chemical agent which will liberate the sulphurous acid.*

Digitized by Google

BISULPHITE OF LIME, BISULPHITE OF ZINC, BISULPHITE OF SODA, TERSULPHITE OF ALUMINIUM.

A manufacturing chemist of New York sent me, last spring, samples of the above-mentioned salts in solution, and I made a number of tests to determine their comparative germicide power. The results obtained indicate that their value as disinfectants depends upon the amount of sulphurous acid which they contain. All of the solutions gave off sulphurous acid gas constantly when not kept in tightly corked bottles; and, in adding them to broken-down beef-stock, an abundant liberation of this gas occurred.

The solution of bisulphite of lime gave the best results. In the proportion of five per cent. this destroyed the vitality of *M. tetragenus*, the test organism employed. The solution of bisulphite of zinc and tersulphite of aluminium failed to destroy the same micrococcus in the proportion of five per cent., but were successful in ten per cent. The solution of bisulphite of soda failed upon the same organism in ten per cent. I have lost my memorandum giving the specific gravity of these solutions, but believe them to have been saturated solutions of the salts named.

XVIII.

THE COMPARATIVE ANTISEPTIC VALUE OF THE SALTS AND OXIDES OF MERCURY.

BY GEORGE M. STERNBERG, M.D.,
SURGEON U. S. ARMY.

IN the introduction to this series of preliminary reports the statement is made that "a complete investigation of both disinfectants and antiseptics being impracticable in the time and with the resources at command, the Committee decided upon so far departing from the letter of the resolutions of Dr. Hibberd as to limit its inquiry altogether to disinfectants, and to omit all investigations into the action of antiseptics."[1]

The present article is the result of a departure from this rule which the writer has made with reference to the salts and oxides of mercury, because of the special interest which they have from a therapeutical point of view, and because of the important indications which seem to be furnished by their antiseptic power for restricting the development of pathogenic organisms in the alimentary canal, as well as in masses of decomposing organic material which might serve as pabulum for disease germs external to the body.

With the assistance of Dr. Abbot, I have recently made a series of experiments, the results of which are given in the following table:

	Active.	Failed.
Biniodide of mercury	1 : 20,000	1 : 40,000
Bichloride "	1 : 15,000	1 : 20,000
Protiodide "	1 : 10,000	1 : 20,000
Yellow oxide "	1 : 1,000	1 : 2,000
Black oxide "	1 : 500	1 : 1,000
Calomel	1 : 100	
Blue mass	1 : 100	

[1] THE MEDICAL NEWS, January 24, 1885, p. 87.

In every case the antiseptic was carefully weighed and added to 100 cc. of beef peptone solution, or of veal broth. A similar quantity of the culture fluid was put up as a *témoin* without the addition of the antiseptic. As the oxides and iodides of mercury are insoluble in water, the bottle was repeatedly shaken in order to dissolve in the albuminous culture fluid as much of the antiseptic as possible. An undissolved remnant could, however, be recognized at the bottom of the bottle after this repeated shaking. Two drops of broken-down beef-stock were added to each bottle to cause speedy putrefaction of the culture fluid in the absence of a sufficiently potent inhibition of the developing power of the bacteria of putrefaction. In every case in the comparative experiment the culture fluid became clouded, and had a putrefactive odor at the end of twenty-four hours.

The first column in our table shows the proportion in which the culture fluid was preserved from any appearance of decomposition for at least a week, the duration of the experiment. In the proportion given in the second column a decided inhibiting power was shown, except in the case of calomel and blue mass, which, in the proportion given (1 : 100), gave no evidence of antiseptic power. The other salts and oxides in the list prevented decomposition for twenty-four hours in the proportion given in the second column; and it was not until the second day that the bacteria of putrefaction commenced to form a cloud at the upper surface of the fluid, which gradually extended until the fluid had entirely broken down, usually by the third or fourth day. The bottles containing the biniodide (1 : 20,000), and the bichloride (1 : 15,000) have now been standing in the laboratory for three weeks, and are as transparent and free from odor as the day they were put up. These results agree with those reported by Miquel.

So far as I know, the antiseptic value of the protiodide and of the oxides of mercury has not heretofore been determined. I shall refrain at present from making any remarks upon the therapeutic possibilities which these figures suggest, or upon the possible explanation of the *modus operandi* of the protiodide, given daily for many months in the cure of syphilis, or of the use of yellow oxide as a remedy for septic fermentation in the alimentaay canal. The still greater inhibiting power of mercuric chloride for the spores of *B. anthracis* has already been referred to in my paper published in THE MEDICAL NEWS o February 21st, p. 206.

The following simple experiment may, perhaps, serve to explain the demonstrated value of calomel as an "alterative" in bowel complaints attended with offensive discharges: If a little calomel is shaken up in a test-tube with putrid beef-tea, a *black precipitate* is thrown down. I have made no attempt to examine this black precipitate chemically, but it can scarcely be anything else than the black oxide of mercury, which my recent experiments show has decided antiseptic power when present in putrescible material in the proportion of 1 : 1000, and entirely prevents the putrefactive decomposition of beef peptone solution in 1 : 500.

HOSPITAL NOTES.

THE CLINIC FOR NERVOUS AND MENTAL DISEASES, BERLIN.

A CASE OF TABES DORSALIS, COMPLICATED WITH PROGRESSIVE MUSCULAR ATROPHY.

Service of DR. MENDEL.

Reported by F. HERBERT HACKER, M.D.,
of Charleston, S. C.

THE patient, who is a shoemaker, 37 years of age, claims to have enjoyed good health, with the exception of the usual diseases of childhood, up to the development of his present disease. Excesses in wine or venery are positively denied. Patient was actively engaged in the Franco-Prussian war, and began to suffer in 1873, from attacks of severe pains in limbs and back, as also from a feeling of constriction over thorax and abdomen; these latter pains he describes as having been of peculiar severity.

He ascribes these symptoms to exposure during the campaign, and he took them at the time for rheumatism. In 1874 the patient noticed that the muscular power of his lower extremities began to diminish; he also began in this year to suffer from severe attacks of what he calls "indigestion," complicated with severe pains in the head. He complains now of urinary trouble—dysuria. The patellar phenomenon is absent; the pupils do not react to changes of light. Paræsthesia seems, however, not to be present. Patient exhibits well-marked ataxia in his gait.

In this case the diagnosis is extraordinarily easy. The gradual inception with rheumatoid pains, the constricted feeling over breast and abdomen (which are almost pathognomonic of the disease in question, and are but rarely absent), the attacks of so-called indigestion, the absence of the reflex movement on percussion over the tendon of the quadriceps, and the ataxic gait, point with positive certainty to but one disease, viz., *tabes dorsalis*, or, as it is sometimes called, *progressive locomotor ataxia*, a disease which has its seat in the posterior columns of the cord, and which usually produces finally sclerotic changes of these columns. The attacks of "indigestion," of which the patient complains, are nothing more nor less than what is so often observed in this clinic, and known under the name of *crises gastriques*. They are very frequent in the course of tabes, and are best treated—as they depend, not on local causes in the stomach itself, but on destructive changes in the nervous centres—with minute doses of morphine; medicines directed against the "indigestion," as such, are useless.

So far everything is quite clear and simple, but on causing the patient to remove his clothing, and examining him more closely, we see other changes which are not so easily explained. First we notice that the muscular system, as a whole, is but weakly developed, and that certain muscles are atrophied to a considerable extent. The rotundity of the left shoulder is entirely gone, owing to excessive atrophy of the deltoid muscle on that side; on the right side this change is not present; on both sides the infraspinati muscles are very much atrophied; the right serratus magnus is so far gone that the flat of the hand can easily be inserted between thorax and scapula; both nates are sunken in from disappearance of the gluteal muscles, so that in place of the normal rotundity of the parts, there are two large hollows, or depressions, on each side. The muscles of the head and tongue are intact. These changes, the patient tells us, have come on gradually, and are progressive in character. Such progressive *atrophia musculorum* may be owing to one of five causes, and we shall endeavor to find out the one which is at work in our present case:

1. It may result from disuse and inactivity of the affected muscles. 2. It may be produced by peripheral neuritis, in which case other changes and symptoms are also present. 3. It may be owing to peripheral disease, as in *pseudohypertrophia musculorum*. 4. It may be consecutive to inflammatory diseases of the articulations. 5. It may be produced by diseases of the central nervous system, more especially by disease of the anterior cornua of the gray matter of the cord, *poliomyelitis anterior*, which may occur either as an acute or as a chronic affection; the acute form constituting the anatomical basis of the so-called "essential infantile paralysis" of Rilliet and Barthez, the chronic form producing the true "progressive muscular atrophy."

In our case there can be no doubt that neither of the first four causes is at all applicable; the patient has always been engaged in active muscular work, which has kept nearly the entire muscular system at work, nor is the atrophy evenly distributed; he has never suffered from neuritis nor from inflammatory joint affections, so that the first three causes can be excluded, and as the atrophy from which he suffers is not accompanied by a corresponding hypertrophy, we may also exclude the fourth case; we can, therefore, have not the slightest doubt that, in addition to the gray degeneration of the posterior columns of the cord, there is a participation in the process of the anterior horns of the gray matter. This is rather a rare complication of tabes, and while changes in the joints have been frequently observed, such changes in the muscular system are of exceedingly rare occurrence. Only day before yesterday we had the opportunity of observing in this clinic a case of tabes accompanied by *mal perforant du pied*, in which the disease had made a hole through almost the entire thickness of the foot.

The way in which the gray matter becomes affected is still an open question; while Prof. Leyden, of this city, holds that the disease of the anterior horns is merely an extension of the morbid process from the posterior columns, the majority of neuropathologists, Mendel among the number, are of opinion that the two diseases are merely coincident, and stand in no causal relation to each other. Further observation is, therefore, necessary to settle this disputed point. As far, however, as treatment or prognosis goes, it is one of very little import. The affection of the gray matter extends sometimes into the medulla oblongata, producing the symptoms of bulbar paralysis, none of which, however, are present, even in the slightest degree, in our case. Of course, such an eventuality can but hasten the necessarily fatal termination. The treatment, of course, coincides with that of uncomplicated tabes, with the employment of the galvanic and faradic currents, used in accordance with the general rules governing their employment.

MEDICAL PROGRESS.

COCAINE IN LARYNGEAL TUMORS.—At a recent meeting of the Russian Medical Society, Dr. N. P. Simanovsky made a communication concerning the favorable results obtained by him by the use of cocaine in laryngoscopic practice. Particularly striking results were met with in the excision of laryngeal tumors. In two out of six of these cases, cocaine was not employed, and in each a period of about two months was requisite to prepare the patient for the operation. In the other four cases where cocaine was employed, the operation was performed on the second visit of the patient to the ambulatorium. Afterwards Dr. Simanovsky exhibited several instruments used in laryngoscopic practice, amongst others one invented by himself, and designed for removing laryngeal tumors.—*British Medical Journal*, August 22, 1885.

CHANGES IN THE PORTAL CIRCULATION CONSECUTIVE TO INTRAHEPATIC ALTERATIONS IN THE BILIARY CIRCULATION.—E. MARAGLIANO, in *La Salute*, f. 3 and 4, 1885, after a clinical study of the results of changes in the intrahepatic biliary circulation as related to changes in the portal circulation, gives the following résumé of his conclusions:

1. Turgidity of the intrahepatic biliary vessels may, by its mechanical effect, arrest the discharge of the blood from the portal hepatic vessels.

2. As a consequence of this impediment to the portal circulation, congestive phenomena in the vessels of the lesser circulation may result, as also tumors of the spleen and even ascites.

3. In catarrhal icterus and in the icterus of biliary retention, and especially in the hypertrophic form of interstitial hepatitis, tumors may result as a sequence of mechanical relation between the biliary and the portal circulations.

If these clinical conclusions do not seem to be confirmed from experiments upon animals, the reason is that the effects of disturbance of the portal circulation in a determined vascular zone are not constant, and also because comparative anatomy shows that in the animal scale there exists great variation in the portal circulation both in reference to its direct relation with the circulation of the cava, independent of the hepatic veins, and in its relation with their various radicles.—*Rivista Internazionale di Medicina e Chirurgia*, May and June, 1885.

SUCCESSFUL OPERATION IN TUBAL PREGNANCY.—DR. F. WESTERMARK describes, in a Swedish medical journal, a case of tubal pregnancy upon which he operated successfully. The age of the patient was 23. She began to menstruate at 12, and always suffered a good deal at the periods. Sometimes she ceased for several months at a time, and for this amenorrhœa she attended the Serafimerlasarettets Polyclinic in 1882. A cure was effected, and she became quite regular. In September, 1883, she was married; she menstruated regularly till December, 1884, when she ceased. In February, 1885, the breasts began to swell, and she believed herself to be pregnant. On the 11th of March there was slight hemorrhage, which recurred three times in a week. On the 19th she had some pain and hemorrhage; thinking she was about to abort, she sent for a midwife. On the 25th Dr. Westermark saw her and found the cervix closed, the uterus enlarged and retroverted; to the left was an elastic tumor about the size of a small fist. The patient being unable to micturate, a catheter was passed and the uterus replaced. She continued in a satisfactory condition for three days, when she was seized with diarrhœa, vomiting, and pain. The next day she was nearly collapsed; she was again catheterized and the uterus replaced. Shortly afterwards a complete cast of the uterus came away. Her condition appearing serious, and being in poor circumstances, she was admitted into the Maria Hospital on April 8th. It was noticed that there was no tenderness on palpation. Above Poupart's ligament a tumor about four-fifths of an inch in diameter was felt. The uterus was enlarged, movable, anteflexed, and displaced to the right, the os being closed. The tumor could be felt to be distinct from the uterus, and was about the size of a goose's egg; it was soft, elastic, smooth, and did not fluctuate. A placental souffle was heard over the tumor. On the opposite side no corresponding sound could be detected. The lungs were healthy; there was an anæmic cardiac murmur; the urine contained some albumen, but no casts; the temperature was normal, and the pulse from 80 to 90. The next day there was some hemorrhage, and on the 15th a recurrence of pain. On April 19th the abdomen was opened under antiseptic precautions. In the peritoneal cavity a quantity of bloody serum and some firm clots were found; the cavity was carefully sponged out, The viscera and serous membrane appeared much injected. The right ovary and Fallopian tube were healthy; the uterus enlarged and soft. To the left lay a tumor the size of a goose's egg, in appearance very like an incarcerated hernia; immediately below, and to the outer side, lay the left ovary. The tumor was soft and very elastic; there were adhesions externally. When pricked with a needle, some bloody serum exuded. It was then ligatured and removed, and the abdomen sponged out with boracic solution and closed with deep and superficial sutures, the wound being dressed with corrosive sublimate gauze. The patient did well. The tumor was egg-shaped, having at one end the cut Fallopian tube, and at the other the fimbriated extremity. No trace of umbilical cord or embryo was discovered in the cavity of the tumor or in that of the abdomen, but traces of chorion and placental tissue were found in the tumor.—*The Lancet*, August 15, 1885.

THE NATURE OF THE SECRETION OF THE FEMALE GENITAL ORGANS.—DR. MÉNIÈRE, in the *Journal des Connaissances Médicale*, at the conclusion of a memoir concerning the nature of the secretions of the female genital organs, makes the following résumé:

1. The secretions of the human organism are, as a rule, alkaline.

2. Those of woman are less alkaline than those of man.

3. The vulvo-vaginal mucus tends to become more acid as the constitution is weak, or when it is produced as a result of morbid processes.

The uterine mucous secretion under the same condition becomes more alkaline. The state of health, therefore, corresponds with a slight acidity of the vulvo-

Digitized by Google

vaginal secretions (with the exception of the glands of Bartholini), and with a moderate alkalinity of the uterine mucus.

4. The changes of composition are proved by clinical facts, chemical analysis, microscopical examination, and particularly by the cure of sterility from certain thermal causes.

5. To changes of composition correspond hypersecretion, a composition immediately different, and the appearance of microörganisms; moreover, the uterine mucous membrane constitutes a region in which parasites neither animal nor vegetable can ever be found.

6. Notwithstanding the variations in composition, the mucus secreted by the muciparous follicles and the vaginal mucous membrane always maintains an acid reaction.

7. The mucus secreted by the follicles of the cervical and corporeal cavities, and finally that of the vulvo-vaginal glands remain invariably alkaline.—*Revue de Thérapeutique*, August 1, 1885.

STROPHANTHUS.—DR. FRASER, Professor of Materia Medica in the University of Edinburgh, is about to publish the result of his researches on the physiological action and therapeutic uses of the "kombé arrow poison" (Strophanthus hispidus), a subject which has engaged his attention for nearly fifteen years. The plant is a woody climber, growing freely in the forests, both of the mountains and valleys of many parts of Central Africa. In the Mangana country, near the Zambesi, it is known as kombé, but in the Gaboon district it is called "inée," "onaye," or "onage." It climbs the highest trees, hanging from branch to branch in graceful festoons like a wood-vine. Its flowers are pale yellow, and last only a very short time during the weeks which immediately precede the rainy season. The fruit ripens in June, and is collected by the natives with much care and many mystic ceremonies. From the seeds is extracted a juice in which are dipped the points of the arrows for shooting wild animals. Dr. Livingstone, in his well-known narrative of the expedition to the Zambesi, refers to its employment in this way, and says that the poison is so deadly that a beast, on being struck, at once falls to the ground paralyzed. The follicles, specimens of which we have examined, are about a foot in length, and contain from 150 to 200 seeds, each bearing a beautiful delicate plumose appendage mounted on the extremity of a thread-like stalk some three or four inches long. From the seeds, Dr. Fraser has succeeded in extracting a principle of very great activity which he has named "strophanthin." When examined under the microscope, it is seen to be composed of myriads of delicate interwoven crystals of all shapes and sizes. Injected under the skin of a frog, it arrests the action of the heart, causing complete stoppage of that organ, the ventricle being found pale and contracted, whilst the auricles are dark and distended. There seems to be little doubt that it acts directly on the cardiac muscular fibre. In physiological action it is allied to digitaline, the active principle of the common foxglove, although it exceeds it in activity, and differs from it in many important particulars. It is probable, too, that it is related to antiarin, the poisonous principle of the deadly upas tree of Java. We believe that Professor Fraser has succeeded in laying down definite rules for its administration in various forms of heart disease, and it is likely that it will be extensively employed. It must be satisfactory to him to reflect that he has been enabled to add to our list of remedies an agent which hitherto has been employed only as an instrument of destruction.—*The Lancet*, August 15, 1885.

INTRA-PARENCHYMATOUS INJECTIONS IN PULMONARY TUBERCULOSIS.—H. TRUC, in the *Lyons Méd.*, May 3, 1885, after a number of preliminary experiments upon dogs, reaches the following conclusions:

1. Intra-parenchymatous injections of alcohol and creasote into the tuberculous lungs at a distance from the hilus, through the first two intercostal spaces, have had no other unfavorable effect than to produce pain, not constant however, and sometimes a slight elevation of temperature.

2. In no case did the inflammation produced by the injection seem to determine caseation, or to have an unfavorable result upon the progress of the tuberculosis, even when made when the lesions were far advanced.

3. The absence of satisfactory results in this last condition induces us to abstain from injections into the lungs in which the lesions are extended.

4. Creasotized injections in some subjects with lesions but little advanced, have been followed by a slight subjective and objective improvement.—*Revue des Sciences Médicales*, July, 1885.

SCARLATINIFORM RASH PRODUCED BY INTESTINAL ABSORPTION OF PTOMAINES.—A patient observed by MM. Lépine and Mollière (*Journ. de Méd. et de Chir. Prat.*, 1884) presented at first nothing abnormal except an artificial anus, the consequence of a strangulated hernia. One day he was suddenly seized with violent delirium, and M. Mollière noticed a considerable dilatation of the pupils. The skin was covered with a scarlatiniform rash, but there was neither fever nor angina. Poisoning by belladonna was at first suspected, but after a careful examination M. Lépine came to the conclusion that the symptoms were due to the absorption by the intestines of ptomaine, acting like atropine, and probably similar to that obtained by Zuelzer and Sonnenschein from putrid substances. After a short time, acute conjunctivitis and fever supervened, and the patient died. At the post-mortem examination a highly offensive substance was found in the intestine below the artificial anus, so that the possibility of an acute auto-intoxication cannot be disputed.—*British Medical Journal*, August 22, 1885.

AMPUTATION OF AN INVERTED UTERUS.—DR. A. GRENANDER publishes in the Swedish medical journal *Hygeia* a case of polypus uteri with inversion, in which the organ was successfully amputated. The woman was 58 years of age, had had six children, and had ceased to menstruate about seven years, when she began to suffer from hemorrhage, and after a time from an offensive discharge, for which she consulted the author, who, on examination, found the os patent and a large soft tumor occupying the uterus, which was about the size of a fœtal head at term. He advised the woman to go to a hospital, but she did not do so. Seven months later she was obliged repeatedly to send for a midwife to catheterize her. Suddenly, a few weeks afterwards,

Digitized by Google

a tumor protruded from the vulva and bled profusely. The midwife diagnosed a polypus, and endeavored to remove it by traction. This proceeding produced so much pain that the patient begged her to desist and to send for Dr. Grenander, who, when he came, found that the tumor, which was the size of two fists, consisted of the inverted uterus and a large polypus attached loosely to it, so that he was able easily to separate them. He then attempted to replace the uterus, but, finding that impossible, ligatured the vagina, which was also partially inverted, and a week later, with the assistance of Dr. Söderström, excised the uterus with a Paquelin's knife at the level of the os internum. Antiseptic dressings were employed. There was but little pain, though no chloroform was administered. Some hemorrhage occurred, and an additional ligature was required. No signs of peritoneal irritation followed, and in eight days the stump had returned to its normal position, being a finger's length from the vaginal orifice. For the first few days the precaution was taken of drawing off the water regularly in order to prevent the wounded surface or the dressings from contact with it. With the exception of some pain of a neuralgic character, which was rapidly controlled by morphia suppositories, no untoward symptoms occurred, and the patient made an excellent recovery. Examination of the amputated uterus showed that it could not have been replaced without damage to its structure.—*The Lancet*, August 22, 1885.

TREATMENT OF ACUTE RHEUMATISM.—At the annual meeting of the British Medical Association, DR. PAVY, in discussing the treatment of acute rheumatism, said that this was one of those subjects upon which the hospital physician might specially feel himself entitled to speak. He had formed a very strong opinion with regard to the salicylate treatment. His experience now contrasted in the strongest possible manner with his experience before the treatment was introduced. Students of the present day had no opportunity of seeing in the wards the disease run its natural course, with all its urgency and severity of symptoms, as they had formerly, when it might be said there was no treatment known that produced any decided impression upon it. To use the salicylate treatment to effect, the agent must be given largely. The usual plan at Guy's Hospital was to give twenty grains of salicylate of soda every two hours for the first twenty-four, thirty-six, or forty-eight hours. By this time the pain was generally removed from the joints, and the temperature brought down, and the patient altogether placed in an easy condition. The frequency of the dose might then be reduced to every three hours, and later to every four and six hours. What he considered of the greatest importance was that, notwithstanding the complete subsidence of the disease, the treatment in a case that was severe should be continued for at least twelve or fourteen days. He sometimes met with a certain amount of discontent in having this carried out. The patient often could not be brought to understand the necessity of being kept in bed, and upon the milk and farinaceous diet to which he was restricted for at least [illegible] time named, and would press for the restrictions [illegible]ed to be removed. His experience led him to c[illegible]e fa[illegible]e that the salicylate treatment, in subduing the [illegible]d fro[illegible]ms as it did, simply controlled the manifestation[illegible] cont[illegible]e disease, without absolutely removing or eradicating that which gave rise to the manifestations. Time was required for this to subside; and if, during this time, the treatment, or that which kept the condition under control was removed, immediately it manifested itself by a return of the symptoms. This was the view that forced itself upon him from what he had seen. It accounted for many of the relapses that occurred, and explained the necessity of keeping the patient under treatment for a definite time, however speedily the disease might appear to have yielded. The treatment did not influence the complication as it did the disease itself. With the disease subdued at once by this treatment, the complications were not likely to arise as under other circumstances; but, if a patient were admitted with pericarditis or endocarditis, this was not influenced in any marked manner by the treatment. Hyperpyrexia was not controlled by the treatment; if it were, the management of this grave condition would be much more easy than it was. The more acute and general the case of rheumatism, the better he considered it adapted for the salicylate treatment. Indeed, in chronic or subacute cases, or where only one or two joints were attacked, he had not found any decided benefit derivable from it. Sometimes the salicylate produced toxic effects, which constituted a barrier to its further administration to the extent required. Directly these toxic effects showed themselves, his plan was to take off the salicylate and administer salicine in a similar dose This, he found, answered what was wanted. He did not begin with salicine in the first instance, as, rightly or wrongly, he was under the impression that the salicylate was the more powerful antirheumatic agent of the two.—*British Medical Journal*, August 22, 1885.

CORROSIVE SUBLIMATE IN OPHTHALMIC PRACTICE.—DR. BELOV, writing in a Russian ophthalmic journal, gives his experience of corrosive sublimate in the treatment of inflammation of the conjunctiva. The cases in which he used it numbered 65, and were made up as follows: 26 of catarrhal conjunctivitis, 19 of the phlyctenulous variety, 2 of the croupous, 2 of the blenorrhagic, and 16 of the granular. The conclusions to which he was led were: 1. Under the use of an extremely weak solution of corrosive sublimate as a spray, inflammatory secretion quickly diminishes, and in a short time disappears. In acute cases the inflammatory infiltration quickly decreases, and in chronic cases there is also a diminution of the infiltration, which, though less marked than in acute cases, is more rapid than when nitrate of silver is used. 2. Phlyctenæ, which quickly disappear when calomel is used, are also rapidly cured by corrosive sublimate. 3. Trachoma complicated with acute or chronic inflammation, in addition to the cure of the latter, shows a diminution in the number of the granulations. 4. In all acute inflammations where nitrate of silver is contraindicated, instead of employing cold and leeches, a weak solution of corrosive sublimate can be used, not only in the form of drops and collyrium, but in extreme cases as a wash applied with a syringe. 5. In chronic inflammations and in the second stage of blenorrhœa a combination of nitrate of silver and corrosive sublimate in solution gives better results than the silver alone. 6. Good results may be anticipated from the use of a weak solution of corrosive sublimate in the

Digitized by Google

form of spray as a prophylactic against ophthalmia neonatorum. The author makes the applications from two to eight times a day, continuing them for half a minute to a minute at a time, according to the quantity and nature of the secretion. The atomizer is always held close to the eye in order that the spray may be blown in with sufficient force to remove the secretion quickly and thoroughly. In all cases the lower eyelid is first turned out and then the upper, each being sprayed separately; in this way the eye is kept open so that the whole surface of the conjunctiva is exposed to the action of the atomized fluid. In cases of phlyctenæ the spray is used with the lower lid slightly drawn out, the upper lid being at the same time held back. The author particularly recommends the sublimate treatment in cases where nitrate of silver is unsatisfactory—*e. g.*, chronic conjunctival catarrh and conjunctivitis in scorbutic subjects, and where complicated with inflammation of the cornea. He considers the use in ophthalmic practice of a solution of the strength of 1 to 20,000 or 1 to 10,000 quite safe.—*The Lancet*, August 15, 1885.

THE REMOVAL OF TUMORS OF THE ABDOMINAL WALL WITH THEIR PERITONEUM.—DR. M. SANGER, of Leipzig, contributes to the *Archiv für Gynäkologie* (Band XXIV. Heft 1) an interesting paper on this subject. It deals with the removal of tumors of the belly wall so closely and extensively applied to the peritoneum that this membrane can only be preserved uninjured by a difficult dissection, after which a large thin sheet of peritoneum, free from its main vascular connections, will be left. In such circumstances some operators have adopted the easier course of cutting away the tumor with its peritoneal covering, and taken great pains to bring together the edges of the peritoneal wound, leaving the skin which covered the tumor as a large loose bag over the stitched-up incision. Others have filled up the gap by stitching omentum into the wound, without great success. Sänger here publishes a case in which he simply stitched together the margins of the incision through the skin and muscles, leaving the large surface from which the tumor had been removed uncovered with peritoneum; so that after closure of the wound a great part of the anterior abdominal wall was left bare of peritoneum Three similar cases have been published before, one by Esmarch, two by Sklifossowsky. All four were successful. In only one of them (Esmarch's) was drainage employed. In order to determine the behavior of the parts affected when this course had been adopted, Dr. Sänger has made experiments upon animals, and he finds that just as after a destruction of skin, healing takes place, and fresh epidermis is formed, so after removal of part of the peritoneum new endothelium is produced. The paper concludes with a general survey of all the cases of tumor of the abdominal wall known to the author.—*Medical Times* (London), August 22, 1885.

COCAINE IN GYNECOLOGY.—The French and Italians allege that they have met with brilliant success in the employment of cocaine for the alleviation of pain in diseases of, or operation on, the female pelvic or external organs. Dr. Dujardin-Beaumetz has described a case of vaginismus which followed lingering labor with retained placenta. Dyspareunia lasted for two years, and the vaginismus was not relieved by forcible dilatation of the sphincter vaginæ under chloroform. The inner surface of the nymphæ and the entrance of the vagina were painted four times with a 2 per cent. solution of hydrochlorate of cocaine. After the fourth application, digital examination or the introduction of the speculum caused no pain or muscular contraction; and a cord-like band, that had previously been felt under the vaginal mucous membrane, had disappeared. Dr. Rusconi has used cocaine freely in the gynecological wards of the Ospitale Maggiore, Milan, generally painting a 2 per cent. solution on the surface of erosions of the cervix before applying nitrate of silver. This greatly alleviated the pain generally caused by caustics. In a case of advanced cancer of the cervix, he applied a plug soaked in three grammes of a solution of 20 centigrammes of hydrochlorate of cocaine in 25 grammes of water. The pain was relieved in a minute, and disappeared in ten, beginning again in an hour and a half. It was found necessary, as might have been expected, to press the plug firmly against the ulcerated surface, in order to produce the full effect. The radiating lancinating pains were much relieved by painting the greater and lesser labia, the vestibule, and the vaginal orifice, with the same solution. These pains, however, soon returned, long before the parts which had been painted had recovered their sensibility. A 3 per cent. alcoholic solution stopped the pain for about a quarter of an hour, but produced a transitory redness over the vaginal mucous membrane, and a burning sensation. The other solution had made the mucous membrane look pale. Dr. Rusconi found that, in some women, cocaine failed to cause the slightest anæsthesia of the vaginal mucous membrane, although the cornea was rapidly affected in the same subjects. His best results with this new drug followed subcutaneous injection in cases of cancer of the uterus, the pains disappearing in six or seven minutes, and not returning for over two hours. By frequent injections, patients that had entirely lost their appetite began to eat heartily. Simultaneous injection of cocaine and morphia produced even better results. The combination of cocaine with atropia was less satisfactory, and seemed to increase the poisonous properties of the latter alkaloid.—*The British Medical Journal*, August 22, 1885.

THERAPEUTIC USE OF HYDROFLUORIC ACID.—DR. EUGENE CHEVY, in a study of the therapeutic use of hydrofluoric acid, finds that,

1. The vapor of hydrofluoric acid mixed with air does not produce the ill-effects hitherto feared. It may be breathed without inconvenience in the proportion of 1 to 1500.

2. Hydrofluoric acid is an antiseptic and antifermentative substance. In the proportion of 1 to 3000 it is able to arrest fermentation in milk, urine, bouillon, and accomplish their preservation.

3. The therapeutic use of hydrofluoric acid in pulmonary tuberculosis, diphtheria, and in the dressing of wounds, from the results already attained, merits further investigation.

4. The vapor must be employed with great care if the patient is affected with asthma, hemophilia, or emphysema.—*Bulletin Général de Thérapeutique*, August 15, 1885.

PHILADELPHIA.

SATURDAY, SEPTEMBER 12, 1885.

SUPRAPUBIC LITHOTOMY, AND SUTURING THE BLADDER.

WITHIN a year SIR HENRY THOMPSON has operated for the removal of stone in the bladder by the suprapubic operation four times, and each time successfully. This measure of success has led him to make public some strong expressions in regard to the merits of this form of lithotomy. After speaking of the capabilities of lithotrity, in *The Lancet*, for July 25, 1885, he says: "The problem thus left remaining for solution, is, What is the best cutting operation for hard calculi (urates and oxalates) which weigh from about two ounces and upwards, as well as for those not quite so large, which are so peculiar in form (as occasionally, but very rarely, happens) that the lithotrite fails to grasp, or retain them? I think there is no doubt about the answer—viz., that it is the suprapubic, and not the lateral operation." And, again, "Finally, I think I am quite justified in believing that unless the operator has had a large experience of lithotrity (and there are not many of whom this can be affirmed) the high operation would generally be a safer proceeding than crushing for a calculus which is hard and much above an ounce in weight." In the same number of *The Lancet*, Professor Humphrey recalls attention to an operation of this sort which he did in 1848 successfuly, and expresses his surprise that the suprapubic operation has not been more frequently performed.

These testimonials to the present appreciation of the operation of suprapubic lithotomy in England mark a distinct advance in public sentiment there, where hitherto this method has had but the faintest and most qualified acknowledgement, and from Sir Henry Thompson himself, hitherto open contempt. Now, however, that so eminent and so conservative a surgeon has given his sanction to the suprapubic operation, its gold may be said to have received the guinea's stamp, and to be current in all the Queen's dominions.

It is now about ten years since the merits of this, then almost abandoned method, were made the subject of thorough study in this country, and warmly championed upon theoretical grounds, as well as supported by analysis of a very large number of cases. At once it began to be practised with increased frequency in America; then it was taken up with new assurance in Austria; then in Holland; then in Germany, where it has always had some friends; then it had a genuine revival in France, and now it has secured the approval of the highest authority in regard to operations for stone in the bladder in Great Britain.

It would appear, therefore, that the time has passed for arguing about the worthiness of suprapubic lithotomy, as a general method; since the old prejudices have gone down so completely before the arguments used in its support, and the improvements introduced in its technique. It would seem that the future of stone operations remains with Bigelow's operation of litholapaxy and suprapubic lithotomy, and the only questions which have now a living interest with regard to the latter are those which pertain to the proper selection of cases and the manner of performing it. In regard to the selection of cases, it would not be easy to improve on what we have quoted above from Sir Henry Thompson. As to the technique, the plan of forcing the bladder up out of the pelvis by introducing a colpeurynter into the rectum, and distending it with air or water, as was first done by Petersen, of Kiel, appears to be of great value. It may, perhaps, be responsible for the moderate hemorrhage reported in some recent cases, on account of the pressure it effects upon the venous plexuses at the neck of the bladder; but it cannot be doubted that it has contributed much to the ease of performing the operation, and invited men to take it up who otherwise would not have done so.

In regard to after-treatment, the most important question concerns the employment or rejection of suturing the bladder.

This would appear to be no question at all if such brilliant results could be obtained regularly as have been affirmed in a considerable number of cases. Thus Bruns, who was the first surgeon to suture the bladder after lithotomy, secured uninterrupted union of the wound in his first two cases, both being little children. This was in 1857 and 1858. (These operations are often erroneously attributed to Lotzbeck, who simply reported them. They were done in Bruns's clinic. The bladder was sewed up during the Crimean war by Baudens, after the removal of a

Digitized by Google

bullet by suprapubic cystotomy; recovery followed. Although this was not a lithotomy, it deserves to be mentioned, as the first case, so far as we know, in which an attempt was made to secure primary union of the bladder after an operation for the removal of a foreign body.) The variety of methods of closing the wound after suprapubic lithotomy is very great, but they may all be divided into those which close the bladder wall independently and those which close this and the wall of the abdomen together. The latter procedure has not been often carried out, although it has sometimes secured a brilliant result. The former has been done a considerable number of times, probably not much less than a hundred. The results have been so far from uniformly successful that it may be seriously questioned whether or not suturing the bladder be a method to be recommended. It will be admitted that this question can only be answered in the affirmative, if theory alone be considered. And, however imperfect may be the success as yet attained by it, the ideal operation of lithotomy must be held to include closing the wound, and securing primary union. This has been done a good many times, and can be done yet more.

But, in the present state of the technique of suprapubic lithotomy, we think it safe to qualify our statement that suturing the bladder is to be regarded as essential to the ideal operation. The ideal operation implies conditions suited to it, and, without going into details, we think it will be acknowledged that such conditions are not found in a considerable number of cases of stone operations. Suturing the bladder is manifestly out of place in cases in which the condition of the bladder is such as to preclude the idea that it can heal up by primary union, or in cases in which free drainage is manifestly a desideratum. Again, it is not suited to cases in which the size, shape, or position of the bladder, or of the neighboring parts is such as to make the procedure very difficult, or to prevent its being accurately—we may say perfectly—carried out. In these cases, certainly, it is far better to treat the wound after suprapubic lithotomy like the wound of perineal lithotomy—that is, to leave it open, and to secure free drainage through it.

For cases in which suturing the bladder is suitable, Znamenski recently proposed to bevel off the internal, mucous edges of the wound, because he believed they got caught and turned in between the united edges when the sutures were tightened, and so prevented union. And Vincent has still more recently suggested bevelling off the external edges of the wound in the bladder, so that, when the stitches are drawn upon, a larger fresh surface shall be brought together, and the chances of union thereby be increased. This idea, which he never put into practice, has been taken up and carried out by GÉZA, of Antal, who reports in *Langenbeck's Archiv*, Bd. xxxii. 2 Heft, 1885, under the title "Eine modificirte Sectio alta," a case of lithotomy and a case of removal of a morbid growth, in both of which he secured primary union by suturing the bladder in this way. The first patient was dismissed, cured, in twelve days, but was really fit to be dismissed in nine days. The second patient made an equally prompt recovery.

The plan of Dr. Géza consists in exposing the bladder by the usual method, after distention of the bladder and the rectum, and then in freshening an elliptical space a little longer than the proposed incision in the bladder and from one to one and a half centimetres in width. This freshening is carried so deep at the line of the proposed incision that there is little left but the mucous membrane of the bladder, which is afterwards incised, and the stone removed. The sutures he uses are of silk, rendered antiseptic with corrosive sublimate; catgut, he believes, gives way too soon. Each stitch is to be applied so as to include all of the bladder wall, except the mucosa. The wound, in Dr. Géza's cases, was covered with Lister's dressing, and a soft catheter left in the urethra.

It is worth while to call attention to this proposition of Dr. Géza, because it is ingenious, and, reasoning from the analogies of operations for vesico-vaginal fistula, its execution may be expected to make the sutures much more reliable than when they were applied in a simpler fashion. It is to be noted, too, that this is a very different thing from the Lembert suture, which is very good in its way, but which seems to offer less hope of prompt union from the apposition of two serous surfaces than this one does from its apposition of two fresh-cut surfaces. In addition to this, the fact that it has already proved so successful in the hands of its proposer is strong recommendation to its further employment.

No study of the plans of suturing the bladder after suprapubic lithotomy would be complete which omitted consideration of an ingenious method used in 1876 by Dr. Starr, of Georgia, his patient recovering in sixteen days. This case was first reported by Dr. Dulles, in an article on suprapubic lithotomy, in the *American Journal of the Medical Sciences* for July, 1877, and again, by the operator, in the *Atlanta Medical and Surgical Journal* for December, 1877. The suture used was of silver wire; it was interrupted; each stitch was passed into the abdominal wall at one side of the wound, and made to include a small portion of the outer layers of the bladder wall; it then passed across the incision and included a similar small portion of the outer layers of the bladder wall on the other side; it then passed up through the abdominal wall to the surface. When drawn tight it slightly inverted the bladder walls, and brought the edges of the abdominal incision

Digitized by Google

close together. It is easy to see that this form of suture must tend to prevent burrowing of discharges between the bladder and the parietes of the abdomen, while it gives a good hold to the stitches which close the bladder itself.

The success obtained by Dr. Starr in its use should encourage others to imitate him. Certainly no better result could be asked for than he obtained.

We sincerely hope that American surgeons will not be backward in contributing their share to the solution of the problem as to the best way to conduct this operation. Its present standing is largely due to their courage in defending and practising it at a time when it was held in much lower esteem than it is now; and we believe the genius in dealing with practical questions in medicine and surgery, which has always been conceded to them, cannot fail to prove of great value if applied to the question of the best method of treating the wound after suprapubic lithotomy.

THE MANAGEMENT OF OCCIPITO-POSTERIOR POSITIONS.

Two valuable papers upon occipito-posterior positions have been contributed by American obstetricians within a year. One of these was by DR. SAWYER, and was read before the American Gynecological Society at its Chicago meeting last fall; the other was by DR. RICHARDSON, and was read at the annual meeting of the Massachusetts Medical Society last June. The subject is one of such great importance, for every obstetrician of even moderate experience has met with difficult cases of labor arising from such position, that we believe our readers will be interested in its consideration.

Both Dr. Sawyer and Dr. Richardson very graphically describe the tediousness of the labor in these positions; both dwell upon the errors of diagnosis, and the importance of external examination to avoid them, and to assist the knowledge gained by vaginal touch. Dr. Sawyer has had an extraordinarily large proportion of cases of occipito-posterior positions, one in five; and he has also had an unusual experience in regard to the general failure of external rotation to occur. The mechanism of delivery when the occiput rotates posteriorly is given by him according to the statement usually found in obstetric text-books—that is, the occiput is born first, then deflexion occurs, the nucha pivoting upon the anterior margin of the perineum. If the perineum be torn, the perineal gutter thus shortened or absent, this probably is true. But when the perineum is entire, we are convinced that Tarnier's explanation of the delivery of the head is the correct one. While the occiput moves along the perineum, greatly distending it, the region of the anterior fontanelle and the top of the forehead are the parts which advance first and correspond to the vulval gap; the occiput, in place of disengaging first, at the level of the posterior commissure, with difficulty arrives there when the entire forehead has disengaged in front.

As to interference in occipito-posterior positions, Dr. Sawyer says he entertains no expectation of the occiput turning forward, if at all, before either the woman or fœtus will demand succor. Dr. Richardson has greater faith in nature; he observes that "the great majority of them require no treatment, beyond a careful watching on the part of the attending obstetrician." Dr. Sawyer advises seizing the head with the hand, and making anterior rotation, this movement is assisted in some degree by the application of the other hand to the body of the fœtus through the abdominal wall. Rotation having been accomplished, the labor may be left to nature, or ended with the forceps. In some cases where anterior rotation can be effected neither by nature nor by art, delivery by the forceps with the occiput posterior is necessary; the most important point in such delivery is to use the forceps especially for producing complete flexion. He prefers the left side position for the patient. The use of the hand to cause anterior rotation, of course, is simply repeating the practice of Smellie.

Dr. Richardson says: "The diagnosis of a posterior position of the occiput having been made, the progress of the case should be carefully watched, with a view to an immediate detection of any failure of proper flexion. The posterior fontanelle should always be easily reached, while the lower the head descends the greater the difficulty in touching the anterior fontanelle, on account of the crowding of the frontal end of the head against the symphysis pubis. If at any time during the progress of the case the posterior fontanelle remain stationary while the anterior is becoming more and more easy of access, the attendant is at once conscious of a gradual extension of the head. It is at this time that an intelligent interference with the case can be of the greatest service. The fingers of the right hand, if the occiput be to the mother's right, should be applied to the frontal end of the head, and, during a pain, a firm resistance, not pressure, should be kept up to prevent any further descent, and the actual flexion of the head should be left to the pressure exercised on the occipital end by the force from above occasioned by the uterine contractions."

It will thus be oberved that Dr. Richardson is much more conservative in his practice than Dr. Sawyer, and regards interference as rarely necessary. But we do not accept the explanation given by the former, in the last sentence quoted, as to the descent of the occiput. It is not pressure exerted on the occipital end that causes its descent, but this occurs because the occipital arm of the head lever meets with less resistance than the frontal arm, and therefore descends.

Digitized by Google

Dr. Richardson asserts that with the forceps applied, if extension has occurred to any degree, the traction made increases the extension, thus facilitating the change of an occipital into a face presentation. A change into a face presentation is impossible if the head be of normal size. As to the alleged evil from the application of the forceps, we believe that the instrument will be found applied very nearly with the blades parallel to the maximum diameter of the fœtal head, and if traction be made, and no effort at flexing the head be attempted, as advised by Dr. Albert H. Smith and most obstetricians, the head will be delivered as pointed out by Tarnier in the quotation we have given; we know, too, this can be done without tearing the perineum, even in a primipara, if the operator will, or can delay the delivery until dilatation is effected. Our objection to the use of the forceps is, that in the application of the instrument there is danger that an oblique occipito-posterior position will be converted into one directly posterior, the occiput rotating into the sacral cavity, and thus an end be put to all hope of anterior rotation. An early resort to the forceps is therefore to be avoided.

Dr. Richardson states that in several cases he has been able to cause both flexion and descent, and consequent anterior rotation of the head, by applying the forceps with the pelvic curve reversed, that is, with its convexity towards the pubes; the cephalic curve should pass over the ears of the child, and the ends of the blades rest on the occiput. "The flexion is often facilitated by pressing the frontal end of the head up with one hand, while the occiput, held firmly within the blade of the forceps reversed, is drawn downwards with the other." Of course, extraction of the head is not to be made with the forceps thus applied.

We are inclined to look upon this method of using the forceps as probably very good, yet it carries with it some dangers, some of which probably could be avoided were one to use some one of the straight forceps,—Churchill's, for example.

Finally, if the head is to be delivered by forceps, the position having become occipito-sacral, the true mechanism of delivery in such a position is borne in mind, and no effort made to drag out the occiput first, for the success of such effort means a tear of the perineum.

EXTEMPORANEOUS EXAMINATION OF THE MILK OF WET-NURSES.

A READY method of ascertaining the character of human milk has not yet been found, uuless an exception be made in favor of that of DR. PAUL HÉLOT, which we find published in the *Journal d'Accouchements* of August 15.

Hélot's method is based upon the proportion between an equal volume of distilled water and of milk; this proportion is 30 to 35, or more simply 6 to 7, that is, six drops of distilled water are equal to seven of milk. A milk having thirty-seven or even forty, gave a good result, but if it fell below thirty-three drops it possessed neither clinically nor physically the requisite qualities.

The milk is taken from the breast by a Pravaz syringe, the needle being removed, and the extremity carefully wiped; the milk should be taken about the middle of nursing, and that from each breast should be examined. The syringe is held vertically, the piston pushed slowly and gently down so that the milk escapes drop by drop, and the drops counted. Then an equal bulk of distilled water may be introduced into the syringe, and the drops counted, or this may be previously known, and a comparison made so as to learn whether the milk has its normal number of drops.

THE INTERNATIONAL MEDICAL CONGRESS.

THE new Committee met again in New York on the 3d inst. All reporters were sedulously excluded from the gathering, and we are, therefore, unable to present a detailed statement of the proceedings.

There were present, either as members or substitutes, Drs. R. Beverly Cole, of San Francisco, Chairman; J. V. Shoemaker, of Philadelphia, Secretary; W. H. Wathen, of Louisville; J. B. Hamilton, of U. S. Marine-Hospital Service; X. C. Scott, of Cleveland; Robert Battey, of Rome, Ga.; E. T. Upham, of West Randolph, Vt.; Ellsworth Eliot, of New York; J. S. Lynch, of Baltimore; A. Y. P. Garnett, of Washington; A. H. Wilson, of South Boston; Wm. Brodie, of Detroit; G. Baird, of Wheeling; Paul B. Sale, of Aberdeen, Miss.; Wm. Watson, of Dubuque; R. A. Kinloch, of Charleston; N. S. Davis, of Chicago; Wm. Pierson, of Orange, N. J.; Austin Flint, Jr., of New York; J. W. S. Gouley, of New York; R. C. Moore, of Omaha; and W. C. Wile, of Sandy Hook, Conn.

The rule of membership was amended so as to give representation to the general societies representing special departments of medicine. The Executive Committee appointed at Chicago was abolished and a new committee appointed, consisting of the President, the Secretary General, the Treasurer, and the Chairmen of the Sections.

The Committee then proceeded to fill the large number of vacancies occasioned by the declinations to coöperate with them. Dr. Henry I. Bowditch, of Boston, was elected a Vice-President of the Congress; Dr. N. S. Davis, of Chicago, was elected Secretary-General; Dr. William H. Pancoast, of Philadelphia, was elected President of the Section of Anatomy; Dr. E. O. Shakespeare, of Philadelphia, President of the Section of Pathology; and Dr. A.

Digitized by Google

B. Arnold, of Baltimore, President of the Section of Medicine.

The Executive Committee was given power to fill all vacancies. Dr. Austin Flint, Jr., was instructed to prepare the report of the Committee to be presented to the American Medical Association, and the Committee adjourned to meet in St. Louis on the Monday evening preceding the next meeting of the American Medical Association.

Without wishing to prejudge the work of the Committee, we cannot refrain from giving voice to the regret that will be universally felt that no effort was made at the meeting to harmonize the grave differences which exist in the profession, and that the expressed views of the European members of the Congress were not deemed of sufficient importance to be accorded consideration.

REVIEWS.

TRANSACTIONS OF THE AMERICAN GYNECOLOGICAL SOCIETY. VOL. IX. FOR THE YEAR 1884. 8vo. pp. 408. New York: D. Appleton & Co., 1885.

OF the special medical societies of our country, there is no one that does itself more credit in its annual volume than the American Gynecological Society, with its fifty-three Fellows; and there is no body of American physicians so well known individually in Europe, by the originality and success of their operations, their contributions to science, and by the frequency of their visits abroad. What names among us are better known abroad, than those of Thomas, Emmet, Barker, Sims, and Battey? Our land is the home of Gynecology. Here ovariotomy had its introduction under McDowell; here anæsthesia, so important to the surgery of women, was discovered, and here the chief improvements in the treatment of vesico-vaginal fistulæ originated under Drs. Sims, Bozeman, and others. Here, also, the Hodge pessary, so highly recommended in England; the Sims speculum, so important in all the surgery of the vagina; the shotted silver suture; the operation of *trachelorrhaphy* by Emmet, and Battey's *oöphorectomy*, were devised. Dr. T. G. Thomas, who revived the operation of laparo-elytrotomy, and Dr. Alex. J. C. Skene, who has saved three women out of four, under it, with three children, are Fellows of this Society. So is also in its honorary list the oldest living ovariotomist, Dr. John L. Atlee, of Lancaster, who followed very early the work of McDowell. Such active, earnest men as these do credit to their country, and it is such that our foreign *confrères* anticipated with pleasure the opportunity of meeting at the International Medical Congress in 1887; men who have made themselves known by their valuable work, and not such who are famous by their schemes to obtain notoriety in ways not always creditable, even if honest and truthful.

The volume under notice contains the monographs of 14 Fellows, and contributions given in discussion by 12 others, making 26 out of the 53, who have been actively engaged in its production. We desire to call special attention to the paper by Dr. J. C. Reeve, of Dayton, Ohio, entitled *Moot Points in regard to Inversion of the Uterus*, as it brings to light the irresponsibilities of the accoucheur in many cases of this accident, which may be valuable testimony in suits for malpractice unjustly brought against physicians. Dr. Reeve shows clearly that inversion may occur as an accident at any period of life—in the young virgin, in the mother, days, weeks, or years after her last labor, and in the multipara, without any special accidental exciting cause, except abdominal pressure acting upon a uterus, softened and relaxed from frequent hemorrhages.

We also call attention to the article of Dr. Paul F. Mundé, on *Interstitial Cervical Fibroids as a Cause of Dystocia, and their Removal by Vaginal Enucleation*, as the plan of removal of such tumors in cases of obstructed labor is one of the means of saving life in desperate conditions of dystocia, otherwise requiring the Cæsarean operation, which, under the circumstances of delay common in such cases, will usually prove fatal, only 3 out of 11 having been saved in the United States. Over a dozen instances of enucleation have been reported, and growths up to 3½ pounds in weight have been removed. When carefully managed, such cases will generally do well, the chief risks being from hemorrhage at the time, or after delivery, and from septicæmia.

Dr. T. G. Thomas reports six additional cases of extra-uterine pregnancy, making twenty-seven which he has had charge of, almost all of them in consultation. He has operated upon a number of patients with the galvanic current, with the effect of destroying the fœtus in the early period, which he now limits to four and a half months. These cases terminated favorably, as did also four others in which he performed secondary laparotomy for the removal of the dead fœtus. He also advises the removal of the living fœtus at maturity, although but two out of seventeen of such operations have not ended fatally, and one of the two children had an encephalocele, of which it soon died. We should like to see Dr. Thomas succeed in such an operation, but even the successes of Jessop, of Leeds, and Martin, of Berlin, are anything but encouraging to an imitator, when he carefully reads over their reports.

We would also call the attention of students of medicine to the paper of Dr. R. Stansbury Sutton, of Pittsburg, on the *Pathology, Diagnosis, and Treatment of Non-malignant Uterine Tumors*, which in seventy pages fully and clearly treats of this class of tumors, and their cure by removal under the knife, the ergotine treatment, and Battey's operation as applied and modified by Mr. Lawson Tait, on February 11, 1872, at the age of twenty-seven. This plan of cure for intramural tumors, known as "Tait's operation," in which the ovaries and Fallopian tubes are exsected, has had very marvellous effects in some cases after almost fatal hemorrhages, of which we are witnesses.

To the gynecological student and accoucheur the volumes of *Transactions* of the American Gynecological Society are of very great value, and we particularly recommend the *discussions* upon the papers, which embody the opinions of a number of Fellows of large experience.

SOCIETY PROCEEDINGS.

AMERICAN DERMATOLOGICAL ASSOCIATION.

Ninth Annual Meeting, held at the Indian Harbor Hotel, Greenwich, Conn., August 26, 27, and 28, 1885.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, AUGUST 26TH.

(Concluded from p. 279)

EVENING SESSION.

DR. L. A. DUHRING, of Philadelphia, read a paper on

THE RELATION OF HERPES GESTATIONIS AND CERTAIN OTHER FORMS OF DISEASE TO DERMATITIS HERPETIFORMIS.

Attention was briefly directed to the previous article of the reader on dermatitis herpetiformis, and to a paper showing its identity with the impetigo herpetiformis of Hebra; also to a preliminary note on the relation of this disease to herpes gestationis and other similar forms of cutaneous disease, read before the Association at the last meeting.

The object of the present communication was to prove the identity of so-called herpes gestationis with the vesicular variety of dermatitis herpetiformis, and to show that the term herpes gestationis is a misnomer, the affection being found in men as well as in women. Secondly, that certain other so-called forms of herpes, such as "herpes pemphigoides," "herpes vegetans," "herpes pyæmicus," etc., as well as certain cases regarded by the reporters as "peculiar forms of pemphigus," must be viewed as examples of this disease; and, finally, that instances of the same affection are also met with in literature under the title of hydroa, and under divers other captions. Numerous cases from English, French, and German literature were cited. The paper of Dr. Duhring was stated to be looked upon as supplementary to the preliminary note referred to, and embodied the results of considerable research into literature. If the views put forth proved to be correct, a great deal had been gained for dermatology in bringing these peculiar forms of disease together.

DR. WHITE thought that the term dermatitis herpetiformis is a misnomer. The disease should be called dermatitis multiformis. The herpetic element is often wanting.

DR. ROBINSON agreed with Dr. White, that the term dermatitis herpetiformis is too restricted, but he should prefer some term which has no significance until the true nature of the disease is better understood.

DR. HYDE said that there are reasons why he should disagree with the last speaker; the term herpetiformis is preferable, if for no other reason than because it is suggestive.

DR. FOX wished to show here a photograph of a case which might be mistaken for dermatitis herpetiformis, namely, erythema multiforme. This disease should be placed in strong contrast with dermatitis herpetiformis.

DR. DUHRING said that the name dermatatis herpetiformis was adopted because it seemed the least objectionable. The herpetiform character of the disease is to his mind characteristic.

DR. G. H. TILDEN, of Boston, then read a paper on

MYCOSIS FUNGOIDE.

He described the case of a man aged 28 years when he came under observation. Three years before several red, desquamating spots had been observed on the elbows. Several months later erythematous spots accompanied with pruritus were noted. These lesions retained a dry scaly character. There were no vesicles or pustules. At the end of a year, several red nodules appeared on the face and throat; these however disappeared. Later a small papule appeared on the right thigh and increased in size; from this there exuded a thin fluid. This was followed by the development in many parts of the body, particularly the axillæ, groins, and neck, of similar lesions, in some cases reaching the size of a hen's egg. After a time there was superficial erosion of some of the tumors, but these excoriated tumors remained firm in consistence, although some of the masses which were covered with epidermis were soft, but there was no evidence of the formation of pus. There was also indolent enlargement of the lymphatic glands. The general health continued good. The patient passed from observation and died at the end of three years and a half.

The report of the microscopist who examined the tumors was read. His opinion was that the growths were lymphangiomatous in character.

Reference was then made to the literature of the subject and the various cases, some thirty in number, which had been reported, were given, and the symptoms and course of the disease were described.

Sections of the growth were also presented for examination.

DR. WHITE said that this patient was under his care during the last stages of the disease and he presented the changes which have been described. Some of the larger growths disappeared. During the last months of his life the man was taking arsenic. Marasmus developed; death resulting from the occurrence of diarrhœa.

DR. ROHÉ, of Baltimore, said that four years ago he saw a case of what he believes to have been the same affection. The man, 62 years of age, had a multitude of these tumors. Several had been extirpated before he came under his care, but there was recurrence with this fungoid appearance. The man was given arsenic, but he died from exhaustion. No autopsy could be obtained. As far as could be detected, there was no affection of the liver or spleen.

DR. MORISON has seen a similar case which was diagnosticated multiple sarcoma of the skin. It takes the microscope, he said, to settle the question in these cases.

DR. FOX had seen one or two similar cases in New York. Should one come under his care, he would try the effect of chaulmoogra oil; judging from its effect in other diseases, it should be useful.

DR. HARDAWAY said that in a case of alveolar sarcoma which he reported, the disease has existed fifteen years, but the clinical features are about the same as they were years ago. There is marked enlargement of the lymphatic glands. The general condition remains good.

DR. HEITZMANN said that the description of the microscopic appearance is that of a lympho-sarcoma,

Digitized by Google

and the examination of the specimens confirms him in this view.

DR. SHERWELL said that to show the amount of involution that may take place, he would refer to a case of melano-sarcoma under his care. The man was treated with arsenic, mercurials, etc. After six months treatment, the tumors have almost entirely disappeared. There was not the slightest evidence of syphilis.

DR. FOX remarked in regard to the use of chaulmoogra oil, that he had seen it used in a case of leprosy. There is now not a trace of leprosy, except the contraction of the fingers, which is however a secondary condition; it has failed in many cases, but there is sufficient to justify a trial of it in the chronic inflammatory affections referred to to-night.

DR. L. N. DENSLOW, of St. Paul, read a paper on

URETHRAL IRRITATION IN THE MALE, AS A CAUSE OF CERTAIN NEUROSES AND OF ACNE.

He prefaced his remarks by a brief review of the cases of contracted meatus reported by Dr. Otis. He then gave an account of a number of cases coming under his observation in which there were reflex conditions associated with such conditions of the urethra as contracted meatus, stricture, and excessive sensitiveness of the prostatic urethra. In these cases removal of the urethral trouble produced an alleviation or cure of the affection to which attention had been directed. He also reported four cases in which the same treatment was followed by marked improvement or cure of the skin disease (acne).

The speaker said that he simply reported the cases as so many observed facts and did not express any theory. He would keep the cases under observation and at a subsequent meeting give a further report.

DR. WHITE asked Dr. Denslow if he had ever used this treatment in females.

DR. DENSLOW said, No. In females in conjunction with external treatment, he depended entirely upon the use of ergotin, six to twelve grains three times daily.

DR. WHITE said in regard to the use of ergot, that he had employed it in obstinate cases, without seeing the least benefit from its use.

DR. TAYLOR protested against the promiscuous cutting of urethras which is so common at present.

DR. SHERWELL believed that acne is largely a reflex disorder, but he is not in the habit of introducing a sound in every case of acne. He gets good results from other measures. He thought that it is valuable in exceptional instances. He strongly believes in the action of ergot in connection with local applications, especially in females.

DR. HYDE said that many of these cases with urethral trouble associated with acne, are patients who probably have been taking for some time balsamic preparations, and as a result they have development of acne. He would suggest to Dr. Denslow that he take this point into consideration.

DR. STELWAGON said that in the past few years he had prescribed ergot for a large number of acne cases, but after a few weeks' administration in many cases, supervening nausea and vertigo compel its discontinuance, nor could he as yet see any positive evidence of its supposed value.

DR. DENSLOW said that in all the cases reported the acne has existed since puberty. The patients were not hypochondriacs and they were not masturbators. He is satisfied that no drugs had been used in any of them.

FRIDAY, AUGUST 28TH.

MORNING SESSION.

DR. C. HEITZMANN, of New York, made some

REMARKS ON ELECTROLYSIS AND OTHER PRACTICAL TOPICS.

He spoke very highly of electrolytic epilation. For this purpose he uses the Leclanché battery. This battery has the advantage of steadiness, absence of pain and of reaction when applied to the face. He employs a needle-handle devised by Leiter, of Vienna. Its special advantage consists in the mechanical arrangement which prevents the needle from penetrating further than the desired depth.

He has had good results from electrolytic destruction of dilated bloodvessels in the face, less satisfactory results in the treatment of port-wine marks, where a permanent cure is only exceptionally attainable. Sodium ethylate is highly recommended by some for the destruction of angioma of the face, but it is in no way superior to nitric acid.

He maintained after observing two hundred cases of falling of the hair, caused by seborrhœa, that the method he recommended in 1876 gave fair results. This is the application of a ten or twenty per cent. ointment of oleum rusci crudum.

For the removal of freckles, the doctor used an ointment recommended to him by Wertheim, of Vienna. The preparation is as follows:

℞.—Hydrarg. ammon. muriat. grammes 3.75.
Magist. bismuthi. . . " 3.5.
Ungt. glycerinæ . . " 30.0—M.

This is to be applied in a thin layer, every other night, and in four to six weeks the result is highly satisfactory. As to the permanency of the cure he was unable to state.

In regard to the reappearance of hair after removal by electrolysis, the speaker considered it to be due to the growth of the fine hairs, whose growth was promoted by the transference to them of the nutrition which should have gone to the hairs removed.

DR. HYDE remarked that Dr. Heitzmann had touched upon the important point in the removal of hair by electrolysis. The question is not what will the result be at present, but what will it be in the future. The electrolysis produces a hyperæmia which tends to stimulate the growth of the remaining hair. He has found the rectified oleum rusci very valuable in certain diseases. He would ask, What is the test for a good crude oil?

DR. FOX said, in regard to the treatment of angioma, that he had used nitric acid, making the application in the form of small dots one-fourth to half an inch apart, with great advantage. In one case, in which a nævus occupied half the face, he used this treatment with much success.

In regard to the return of the hair after electrolysis, if the needle is carefully inserted, and, after the operation, gentle traction is sufficient to remove the hair, that hair will not return. In some cases there is a constant

Digitized by Google

increase in the downy hairs from some cause, but these are exceptional cases. He did not think that the removal of hairs increased the growth of others. In one case, that of a young woman with a strong beard, he removed, by actual count, eight thousand hairs. This process required two or three years. Since then it has been necessary to remove only a few dozen hairs.

DR. ROBINSON used a similar ointment for the removal of freckles, but its effect is only temporary. He thinks that the growth of the remaining hairs is increased by the removal of a portion.

DR. WIGGLESWORTH, for the past fifteen years, has used the following ointment, which is almost identical with that mentioned by Dr. Heitzmann:

℞.—Hydrarg. ammon. . . . parts 10
Bismuthi subnitratis . . " 10
Vaseline . . . . . " 100—M.

DR. DUHRING considers the oil of rusci valuable in seborrhœa of the scalp. The objection to it is its disagreeable odor. He has also used in chronic seborrhœa of the scalp a preparation of sulphur with satisfactory results, but he does not consider it as efficacious as tar.

DR. HARDAWAY has performed the operation of electrolysis for ten or twelve years, probably longer than any other member of the Association. He uses the iridoplatinum needle, which has the advantage of being flexible, and, hence, is not likely to pass through the follicle wall. The moment the follicle is entered, there is usually an escape of sebum. One case, that of a woman with a heavy black beard, has been entirely relieved. Electrolysis with a fine needle affords a method of getting rid of freckles. The plan is to dot the needle over the surface covered by the freckle.

DR. HEITZMANN said that the percentage of recurring hairs is greater in some situations than in others. In the submaxillary region, it is greatest. The oil of rusci crudum is better than the rectified oil. To test it, add alcohol to a small portion of the oil and paint it on the skin; if it evaporates quickly, leaving a thick black coating, it is a good crude oil.

DR. R. W. TAYLOR, of New York, read a paper on

SYPHILITIC REINFECTION.

He first referred to the literature of the subject, and gave a brief review of the authentic cases on record, giving the names of the reporters. The number of cases previously reported is between thirty and forty. To these he added the histories of three more. A fourth case has been observed by him, but as the complete history was not prepared, it was not given.

Case I.—A barkeeper, aged 25 years. Was first seen in 1868, suffering with gonorrhœa. Three years previously he had had indolent enlargement of the lymphatic glands in the groins. Examination showed the presence of lymphatic enlargement in certain regions. Inquiry into the history showed the existence of a chancre three years before, which had been slow in healing. About two months later, he became sick, and suffered with a roseolous eruption, sore throat, falling out of the hair, and rheumatic pains, worse at night. Under treatment he improved, but afterwards exhibited a papular eruption. He was then seen by Dr. Van Buren, who pronounced the case one of syphilis, and ordered mercurial treatment. He recovered after two years, but of his own accord continued the treatment two years longer. He then remained well until the attack of gonorrhœa.

In February, 1870, he again appeared, presenting a typical indurated chancre on the cutaneous aspect of the penis. It presented every evidence of a primary infection. Later a papular syphilide appeared over the body. There were several mucous patches on the pillars of the fauces, and the throat was red and swollen. The joints soon became the seat of nocturnal pains. The patient also presented a form of syphilitic epididymitis. Under mercurial treatment there was some improvement, but a year later there were some tertiary manifestations. By 1874 he seemed very well. During the next three years there were no evidences of syphilis, but he continued the mixed treatment.

He was again seen in the fall of 1882, when it was learned that his good health had continued, and that he was the father of a healthy child. The child was examined, and no evidence of hereditary syphilis detected.

Case II.—Had in June, 1873, a typical indurated chancre, followed by distinct secondary symptoms, which disappeared under treatment. He then passed from observation. In February, 1874, he presented several ulcero-tubercular lesions on the outer aspect of the forearm. He then remained under treatment six months. In January, 1875, he had spots of thickening of the periosteum of both tibiæ. He was again treated with benefit.

In June, 1878, there was a typical indurated nodule on the prepuce, from which indurated lymphatics extended to the inguinal lymphatic glands. The incubation of this sore had been about twenty days. This was followed by malaise, sore throat, swelling of the postcervical and epitrochlear glands. Over the trunk and arms there was a fine mottling of light pink color. The patient then went to Europe, and was not seen until March, 1885, when it was learned that the symptoms had been well marked, and that he had been treated for them under several European physicians.

Case III.—Aged 41. Had had a typical indurated chancre in 1874. There had been inguinal adenitis, followed by roseola, falling off of the hair, and later by severe iritis of the right eye. He was treated with mercury.

In February, 1882, he returned with a typical hard chancre. In April he became sick, had rheumatic pains and a mixed eruption of erythematous and papular syphilide. In May, inflammation of the iris of the right eye again appeared. In 1883 he had a late secondary rash.

These cases were reported with the object of throwing some light upon the natural history of secondary infection of syphilis. In all these cases, relapsing indurations were carefully excluded.

DR. HYDE said that in his experience he had had but two cases of reinfection of syphilis, where he was perfectly sure of the fact.

DR. H. W. STELWAGON, of Philadelphia, then made some

OBSERVATIONS ON THE OLEATES.

In regard to the chemistry and preparation of the various oleates, both as to their manufacture by the direct combination of the acid with the base and by

Digitized by Google

double decomposition, almost, if not entirely, as much can be found in the English translation of Gmelin's *Handbook of Chemistry*, published 1866, as in the writings of the past several years.

Of all the oleates, those of mercury, zinc, bismuth, and lead only have a place in the treatment of diseases of the skin, and in view of their costliness, the seemingly unavoidable frequency of badly made preparations, the disagreeable oleic acid odor, and the irritation so frequently observed following their use, it is probable that of these four, the mercuric oleate is the only oleate that promises to retain a permanent value. This last is especially valuable in ringworm of the scalp, but for inunctions in the treatment of syphilis it is of doubtful utility, not comparable to blue ointment. Oleate of copper, which has been so highly recommended for ringworm of the scalp, although like all parasiticides, useful in recent cases, is of no value in chronic cases, and is far inferior to oleate of mercury and to tar and sulphur preparations.

DR. TILDEN agreed with Dr. Stelwagon, that oleates are not as useful as the ordinary ointments.

DR. WIGGLESWORTH has practically renounced all oleates except the oleates of zinc, lead, and mercury, the last of which he uses as a parasiticide.

DR. DUHRING said that his experience with these preparations is in accord with that of the reader of the paper. He had employed the oleate of copper in varying strength in thirty or forty cases of ringworm of the scalp, but it seemed to exert no influence whatever. These were, however, obstinate cases. Other methods of treatment were afterwards tried and the cases were finally cured. As to its efficiency in acute forms of ringworm he was not prepared to speak.

DR. HEITZMANN had tried the oleate of copper in chronic cases of ringworm of the scalp without any result, but in the acute cases it cures after a time. Even in such cases, however, it is not as efficient as the preparation recommended by Dr. Taylor—that is, four grains of bichloride of mercury to the ounce of tincture of myrrh or benzoin.

DR. FOX referred to the comparison between oleates and vaseline. It has been claimed that the oleic acid and animal oils are better absorbed than these other preparations. As a matter of experience, he has found that vaseline makes a better base for the majority of ointments than do the animal oils. Has also found vaseline a most soothing application to the skin. He has been disappointed in the oleates.

DR. TAYLOR said that his conclusions in regard to the oleates are in accord with those of the paper. He only uses at present the oleates of mercury and zinc, but he never relies on the oleate of mercury in the inunction treatment of syphilis when blue ointment is obtainable.

DR. HARDAWAY had almost entirely discarded the oleates. In some recent cases of ringworm the oleate of copper has seemed to be successful, but in chronic cases it entirely failed.

DR. ROHÉ said that the oleates in his hands have been unsatisfactory.

DR. STELWAGON had only to add that he had hoped that the claims made for the oleates might have greater foundation in fact, but the more he had used them the less they seemed worthy of confidence.

DR. L. N. DENSLOW, of St. Paul, then reported

A CASE OF SYPHILITIC APHASIA AND PARAPLEGIA, FOLLOWED BY DEATH, WITH AUTOPSY.

His object was simply to put on record a case in which an autopsy was obtained in early syphilitic cephalalgia. The patient was seen in consultation April 20, 1885. Two months previously the patient had begun to suffer with severe headache, worse at night. There was also a papular eruption. He acknowledged the existence of a sore six months previously. Iodide of potassium with chloral had been given. Two weeks later the patient was free from pain, but it returned one month afterwards, when the patient stopped taking medicine. Iodide of potassium was again given with the effect of relieving the pain. Aphasia and paraplegia then developed, and the patient died four days later, and within nine months of the initial lesion.

At the autopsy, the dura mater, along the superior longitudinal sinus, was thickened and adherent. There were numerous small gummata in the pia mater, situated along the right border of the longitudinal sinus, and extending back to the fissure of Sylvius. The pia mater exhibited the evidences of simple acute inflammation.

CANADA MEDICAL ASSOCIATION.

Eighteenth Annual Meeting, held at Chatham, September 2 and 3, 1885.

THE PRESIDENT, WILLIAM OSLER, M.D., IN THE CHAIR.

(Specially reported for THE MEDICAL NEWS.)

SURGICAL SECTION.

DR. CARSTENS, of Detroit, read a paper on

TWO CASES OF REMOVAL OF UTERINE FIBROIDS.

The first case was that of a woman aged 40, in whom uterine fibroid was diagnosticated within the broad ligament, and abdominal section determined on. The operation was performed with strict antiseptic precautions. On opening the abdomen, a large tumor was discovered within the broad ligament of right side and one small one. The ovaries were very adherent and were removed. The pedicles were ligatured and the tumors taken away. There was considerable hemorrhage, and some twenty vessels had to be tied with silk and catgut. The patient for the first few days had considerable vomiting. On the fourth day she asked for lager beer, which was given, and had the effect of controlling the vomiting. The temperature up to eleventh day never reached 100° F., but then rose to 102°. This elevation was caused by a small abscess, which formed in the corner of one of the ligatures. The patient did well after this, and was discharged, cured, five weeks after the operation.

The second case was that of a married woman, aged 45, who had had enlargement of the abdomen for several years, with repeated uterine hemorrhages. Dr. Carstens, on examination, found a submucous fibroid. She was dilated with great difficulty, so a posterior incision had to be made. The tumor was enucleated and removed with an écraseur, and the wound in the cervix sewed up with silk ligatures. The patient was able to sit up in six days.

Some remarks were made on the cases narrated, in which the reader of the paper strongly insisted on the necessity of an abdominal section in many of these

Digitized by Google

cases, and said that, until the abdomen is opened, it is impossible to tell what may be the character of the operation it is necessary to perform.

In the discussion which followed, DR. GARDNER, of Montreal, said that, in incising the cervix, he preferred the bilateral incision to the posterior, and that in the cases performed by him he has avoided sewing up the wounds thus made. After removal of the tumor, he is in the habit of irrigating the uterus with two tubes, which are kept in position by stitching to the cervix. He washes out the uterus through these tubes every two hours. In certain cases he is in favor of removing the ovaries, but not in all, as in those of Mr. Lawson Tait.

DR. CARSTENS, in reply, said that section of the cervix is seldom necessary, as it can generally be sufficiently dilated to remove any ordinary tumor, and he has made a posterior incision only because it was most convenient in that particular case. If abdominal section was performed for uterine fibroid, he preferred excision of the tumor to removal of the ovaries and appendages, as by the latter method the growth of the tumor is frequently not arrested. He strongly insisted on the necessity of folding in the peritoneum after the excision of the tumor, as by this means blood is prevented from entering into the peritoneal cavity.

DR. FULTON, of Toronto, then read a paper on

SUBPERIOSTEAL AMPUTATION.

This method of operating was advocated by Walthier seventy years ago; in 1859 it was advised by Ollier, of Lyons; and lately many surgeons have recommended it. Dr. Fulton has performed many amputations recently by this method, and is strongly in favor of it, especially in amputations for diseased bones and joints. After carefully describing the operation, Dr. Fulton mentioned its advantages, the chief of which is that the cut cord of the bone is brought into contact with the tissue most suited to it; also the bone does not become adherent to the end of the stump, and the medullary canal is closed by new bone. The operation is especially suitable in cases where the contents of the medullary canal are soft and in an unhealthy condition. The only objection is the possibly too great development of osseous tissue about the end of the bone. The reader of the paper, however, had never seen any osteophytes result from the operation. Cases were related showing the advantages of the operation.

DR. MCGRAW, of Detroit, remarked that Langenbeck had performed subperitoneal amputation in 1862; but, as the case did not turn out very well, he did not continue to adopt this procedure in his amputations. Dr. McGraw believed that it is most important in amputations to draw together similar tissues, and he always sews periosteum to periosteum, muscle to muscle. In this way the wound is completely closed and no cavity left. He strongly approved of the subperiosteal method of amputating.

DR. DONALD MACLEAN, of Detroit, said that many of the so-called advances of modern surgery are of very questionable benefit, but the one recommended by the reader of the paper seemed to have much to recommend it. It is the duty of the surgeon to pay more attention to the details, not only of the operation, but of the after-treatment, and to make the path of the surgical patient as smooth as possible by doing everything to avoid unpleasant after-results.

DR. DAVIDSON, of Toronto, thought the operation should be more practised than it now is. He thought that in performing the operation the periosteum should be reflected back before the bone is cut, thus necessitating only one division of the bone. The recurrence of osteophytes is certainly an objection to the operation.

DR. SAMPSON, of Blenheim, Ont., said that country doctors are not always able to carry out all the minute details of modern surgery, and yet got very good results. He mentioned a case in which he had lately amputated the thigh, and the patient was going about on crutches within three weeks.

DR. SHEPHERD, of Montreal, said that in his experience the results obtained in amputations performed with periosteal flaps are no better than in those performed without them; that if amputation be done with proper antiseptic precautions, union occurs by first intention, and the result is that the skin is freely movable over the end of the bone. In the last twenty major amputations he had performed, only one did not unite completely by first intention. He thought that the suturing of muscle to muscle, as recommended by Dr. McGraw, is not necessary, as the same result can be obtained by dressing the stump with pads of jute, or some other elastic substance, and keeping them in place with an evenly and firmly applied gauze bandage.

DR. SHEPHERD, of Montreal, read a paper on

EXCISION OF THE TONGUE BY SCISSORS, WITH PRELIMINARY LIGATURE OF THE LINGUAL ARTERIES.

He said that in excising the tongue for malignant disease, besides the necessity for avoiding hemorrhage, it is important that structures in the neighborhood which had become involved should be removed, and he held that the operation of excision of the tongue with preliminary ligature of the linguals facilitates the removal without adding much to the risk of the operation. Whatever operation for excision of the tongue is practised, the mortality in a given number of cases is about the same, and the method of operating seems to have less effect on the results than the after-treatment. Still, certain operations are more favorable than others as regards the recurrence of the disease, as the more completely the disease is removed the less likely is it to return. He considered that in excision of the tongue it is as important to excise diseased glands in the neck as it is to remove diseased axillary glands in extirpation of the breast. The operation was described, and the difficulties met with in ligaturing the linguals especially dwelt on. The advantages of the operation are that (1) the diseased structures, and especially the glands, are easily discovered and removed through the incisions made for ligaturing the arteries.

(2) The removal of the tongue is bloodless, and there is little fear of secondary hemorrhage.

(3) Drainage of the mouth can be more thoroughly carried out by means of the incisions in the neck.

(4) The operation is performed with few instruments, and only those possessed by every surgeon.

(5) The tongue is more completely removed by scis-

Digitized by Google

sors than in any other way, and the tissue is not bruised as when the écraseur is used.

Dr. Shepherd related three cases of malignant disease of the tongue with involvement of the glands of the neck (and in one case of the right tonsil), in which he had performed this operation. The after-treatment is important, and Billroth's method of stuffing the mouth with iodoform-gauze was strongly advocated by the reader of the paper.

DR. MACLEAN, of Detroit, said that in certain cases the operation described by Dr. Shepherd was the proper one, but when there is no involvement of the glands of the neck he prefers removing the tongue with the écraseur. The great danger of all the operations for the removal of the tongue is septic disease of the lungs.

DR. GRANT, of Ottawa, had listened to the paper with great interest, and intended, when a proper case presented itself, to practise the operation. He related a case of deep-seated abscess of the tongue which had lately been sent to him as one of malignant disease.

DR. ATHERTON, of Toronto, did not think ligature of the lingual is a very simple operation. He advocated the performance of preliminary tracheotomy in excision of the tongue, as by this means the wound is kept aseptic and septic involvement of the lungs prevented. There is also less fear of hemorrhage, and greater facility in arresting it.

DR. SHEPHERD, in reply, said that he doubted whether diseased glands in the neck could be always discovered by external manipulation, and that only in cases seen very early should the neck incisions be omitted. He could not help thinking that preliminary tracheotomy added to the risk of the operation, and, besides, it is not necessary if the after-treatment with iodoform-gauze be carried out in the way recommended by Prof. Billroth, who has had no deaths or serious complications in his last seventeen cases.

DR. WM. GARDNER, of Montreal, now read the report of a case of

DOUBLE UTERUS WITH ATRESIA AND HÆMATOMETRA OF THE LEFT CHAMBER.

The patient, a tall, slim, unhealthy looking maiden, æt. 18, was admitted to the gynecological service of the Montreal General Hospital with a history of intense periodic pain in the loins, hips, and hypogastrium. She had always been healthy till two years previous, when she began to grow rapidly and to menstruate. Catamenia always scanty; one napkin; intervals three to six week. The flow attended with moderate pain. Nine months previous to entering the hospital she began to suffer from the pains described. The pain came on each afternoon or evening, and lasted several hours, with an interval of complete relief. Had noticed for some time a swelling of the lower part of the abdomen. No bladder symptoms; appetite small; no vomiting; constipation troublesome. On palpation of abdomen there is an elongated, smooth, very firm tumor extending from the left anterior superior spine of ilium to pubes. Two smaller projections attached to the larger one extend towards the right side of the pelvis. Patient etherized for vaginal and rectal examination. Hymen entire, but perforate. Immediately on entering the vagina the finger meets a very firm, smooth, at one point slightly elastic, mass, evidently the lower part of the hypogastric tumor described. On the left side the vaginal wall is pushed down by the tumor to near the orifice. On the right side and behind the finger can be swept around the tumor to the upper part of the pelvis. No trace of vaginal portion to be detected. The only evidence of an opening is a slight linear furrow. An aspirator trocar was introduced, when a small quantity of thick chocolate-colored blood escaped, thus clearing up the diagnosis. A bistoury was introduced and a free incision made. Fifty fluid-ounces of thick, tarry blood escaped. After partial emptying of the sac it was easy to feel the os uteri of the left patent chamber of the uterus. Double drainage-tubes were inserted within the opening and stitched to the edges, the ends protruding from the vagina. Irrigation every two hours with weak carbolized fluid was ordered. Within the first twenty-four hours the temperature ran up to 103°, but at the end of another day became normal. Very little pain. Patient did perfectly well for a week, but on the eighth day the tubes ulcerated out. Within twenty-four hours the temperature slowly rose to 101°. The patient was again etherized, a portion of the wall of the sac excised, the tubes again inserted, and irrigation resumed. But the temperature and pulse continued to rise. Three days later there was a rigor, followed by profuse sweating; then increase of pain, abdominal distension, left infra-mammary pain, and pleuritic friction; vomiting, at first of mucus, then of coffee ground-like fluid; death nineteen days after operation.

At the autopsy general recent peritonitis with profuse exudation of lymph. Bicornate uterus: left chamber measures one and three-quarters inches; the interior of the right chamber contained the thick menstrual blood-stained brown fluid. Right ovary somewhat enlarged, otherwise healthy. Left Fallopian sacculated, the sacculi containing the same tarry fluid. A sacculated similar collection of the size of an orange, the walls of the sac being formed by the fimbriated extremity of the tube, the broad ligament, and false membrane. Other smaller hæmatoceles were found about the left broad ligament and left border of the uterus. The left ovary could not be distinguished.

DR. GARDNER remarked upon the great rarity of the case. Professor Olshausen, of Halle; Dr. Galabin, of London; and Dr. John Homans, of Boston, had, however, reported exactly similar cases. The prognosis in all such malformations is grave. The treatment, so far as it went, he believed to be the best that could have been adopted, but he regretted that when the condition of the patient became so desperate, he had not opened the abdominal cavity, removed the left Fallopian tube and ovary, opened the other hæmatocele collection, and drained the abdominal cavity. In view of certain recently published remarkable cases of acute and chronic peritonitis, similarly treated with success, he believed it possible that the patient might thus have been saved. Olshausen's case was treated by three successive tappings of the tumor through the vagina. Mild peritonitis resulted, but the patient recovered perfectly, and subsequently married and bore three children.

In Dr. Homans's case, there being doubt as to the nature of the tumor, he opened the belly, clamped and removed the closed uterine chambers containing the altered blood, together with a diseased and distended

Digitized by Google

Fallopian tube and ovary, and introduced a drain. The patient recovered. Dr. Galabin's case was treated similarly to Dr. Gardner's, but less efficiently on account of the intractability of the patient and her friends. She died within a fortnight.

DR. ROSWELL PARK, of Buffalo, reported a successful case of

EXTIRPATION OF THE LARYNX FOR MALIGNANT DISEASE,

and exhibited the specimen, as well as a model, of an artificial larynx after Gussenbauer's pattern. The case was that of a man, aged 64, who for many years had been troubled with hoarseness. For a year past he had lost his voice altogether; last fall consulted a specialist, who diagnosticated papillomatous disease of the larynx undergoing cancerous degeneration. Had previously underwent several operations for removal of the papillomatous growths. He was seen by Dr. Park on the 14th of last June, and at that time tracheotomy was performed to relieve the difficulty of breathing. After some days the granulation tissue about the tracheotomy wound was so exuberant that it forced out the tube, so extirpation of the whole larynx was advised and agreed to by the patient. The operation was performed on the 28th of last June. It was very tedious, but attended with but little hemorrhage. The epiglottis was left behind, and the first ring of the trachea removed with the larynx. The wound was packed with iodoform gauze and healed rapidly. The patient was fed for the first few weeks by a tube passed through the wound. Since then he has taken all his nourishment by the mouth. He is now wearing an artificial larynx, and can swallow well and talk with ease. The removed larynx was exhibited and showed the malignant disease completely blocking up the rima glottidis. The affection was apparently confined to the larynx. Dr. Park said that, up to the present time, 94 extirpations of the larynx had been reported, and that this was the 95th, and the third extirpation that had been performed on this Continent.

DR. ATHERTON, of Toronto, then read a paper on

TWO CASES OF LAPAROTOMY PERFORMED FOR UTERINE MYOMATA.

In the first case the tumor was of considerable size and intra-ligamentous. The pedicle was first transfixed with pins and compressed with a rubber bandage; the tumor was then removed by a wedge-shaped incision. The vessels were ligatured and the pins and bandage removed. The two edges of the stump were then sewed together and the abdominal wound closed with silk and catgut ligature and drained. The patient did well, recovering perfectly. There was a little suppuration about the wound. The operation was performed under the spray.

The second case was that of a young lady aged thirty-five, who had had an enlargement of the abdomen for some years, with recurrent hemorrhages. The case was recognized as one of uterine fibroid. Medical treatment proving of no avail, the patient requested that operative procedures should be undertaken for her relief. Dr. Atherton, on opening the abdomen, found a large tumor filling up the posterior part of the pelvis and firmly adherent. It was transfixed with needles and a rubber tourniquet placed below them; the adhesions were separated with the finger, and as the tumor was freed the rubber tourniquet was pushed further down. The adhesions were very extensive, and the hemorrhage troublesome. The tumor was removed by a wedge-shaped incision, as in the former case, and the edges of the wound brought together with silk and catgut. When the rubber tourniquet was removed there was free bleeding, and the patient suffered considerably from shock after the operation. The abdomen was closed in the usual way, and a glass drainage-tube was introduced. The operation was performed under the spray, and the wound dressed with carbolized gauze. The patient did badly, and was in such a weak condition on the third day that transfusion was performed, and the abdomen washed out with a solution of carbolic acid, 1 to 40, but she continued to sink after a short rally, and died on the fifth day after the operation. At the autopsy gangrenous patches were found on the sigmoid flexure of the colon and the rectum. The uterine stump looked well, and there had been no hemorrhage. In the remarks made on the two cases, the reader of the paper said that in cases of uterine myoma when remedial treatment fails and oöphorectomy has not caused the tumor to diminish, the removal of the growth is indicated, especially in those cases where the system of the patient is running down. He had hopes that in the future the result of operations for removal of uterine myomata would be as favorable as after ovariotomy. He suggested that before the removal of these tumors the cervix of the uterus should be closed by a preliminary operation, to prevent the entrance of germs. This would be a more scientific method than the use of iodoform suppositories or iodoform gauze.

DR. GARDNER, of Montreal, congratulated Dr. Atherton on the success of the first case, and said that everything possible had been done in the second. He thought the suggestion, made by the reader of the paper, of closing the cervix was a valuable one.

DR. ECCLES, of London, Ont., had listened with great interest to the paper, and said that the removal of part of the uterus with a myoma is a dangerous operation, and gives rise to great shock. He had once removed the uterine appendage and a fibroid in a woman aged fifty-nine. There was great hemorrhage, which was with difficulty arrested. The tumor was removed with a wire écraseur. The abdomen was cleaned, but there was free suppuration, and the wound did not close for some time. The woman eventually recovered.

DR. JENKS, of Detroit, never had a case of recovery where there were extensive adhesions in Douglas's cul-de-sac. He thought that in these operations the preparatory treatment is most important. The bowels should not only be thoroughly emptied, but tympanites should be guarded against. Ten to twenty grains of ox-gall should be given daily for a week before operation, and rhubarb and soda on alternate nights, and the night before operation the bowels should be well washed out with enemata containing ox-gall. This method had been very successful in his hands in preventing tympanites.

DR. ROSWELL PARK, of Buffalo, related a case in which he had assisted to remove a large fibroid of the uterus, and where there was great hemorrhage after the operation. The abdomen was reopened, the hemorrhage arrested, and the cavity washed out with antiseptic solutions. The patient made a good recovery.

Digitized by Google

DR. FULTON, of Toronto, said that he also had great trouble with clearing out the contents of the bowels to prevent tympanites. He thought that the method of drainage into the vagina has not been sufficiently tried, and believed it a most scientific and rational procedure.

DR. RUTHERFORD, of Chatham, now read a paper on

SUPRAPUBIC URINATION.

After giving the causes of complete retention and stricture, enlarged prostate, etc., he went on to describe the suprapubic tapping with trocars, and the introduction of a soft catheter. He described four cases, in illustration, where the operation had been performed for retention following enlarged prostate. In one of the cases the patient had been comfortable for four and a half years, urinating through the suprapubic opening. In another case the patient, after urinating for some time through the artificial opening, was able afterwards to pass his water by the natural passage.

DR. BURT, of Paris, Ontario, read a paper on

INTERNAL URETHROTOMY.

He described the operation fully, and related cases in illustration. He used Maisonneuve's instrument. He said that he had never seen any evil results follow the operation, except in one case of penile stricture, where he had cut too deeply, extravasation followed. He had frequently operated most successfully in very severe cases and with permanent relief. He considered the operation to be easy of performance and safe, and that in most cases it was followed by permanent cure. He operated on many cases of stricture after this method, and found that the cutting of these anterior strictures caused the spasmodic stricture of the deep urethra. The instruments used for detecting and cutting strictures were exhibited.

DR. SHEPHERD, of Montreal, could not agree altogether with Dr. Burt's views as to the necessity of internal urethrotomy in all cases of stricture. He himself had rarely found it necessary to perform this operation, as the cases needing it were few—such as penile stricture and resistant stricture. He preferred gradual dilatation in the treatment of stricture, and considered it a much safer procedure than internal urethrotomy, as the mortality in that operation even in such skilful hands as those of Sir Henry Thompson was three per cent. He did not believe in strictures that were detected by a No. 25 sound, and thought that Otis's urethrotome showed only that the urethra was less dilatable in some parts than others; and he thought that the good results following cutting in such cases are due to the moral effect of the operation in hypochondriacs.

(To be concluded.)

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Thirty-fourth Annual Meeting, held at Ann Arbor, Michigan, August 26–31, 1885.

(Specially reported for THE MEDICAL NEWS.)

THE Thirty-fourth Annual Meeting of this Association was begun on August 26th, under the presidency of PROF. H. A. NEWTON, of New Haven. A number of papers of medical interest were presented, of which the following are abstracts:

PROF. W. R. NICHOLS, of Boston, Vice-President delivered the Annual Address before Section C (Chemistry). He took for his subject,

CHEMISTRY IN THE SERVICE OF PUBLIC HEALTH.

It is peculiarly appropriate that chemistry should serve the public health, because many of the dangers to which public health is liable result from the industrial and other applications of chemistry itself.

In studying our surroundings let us begin with the air, considering its normal condition and the changes due to crowding of individuals and pursuit of manufacturing industries. We must also investigate the atmosphere beneath us—the ground air. The water we drink, our food and its adulterations, the clothing we wear, the houses we inhabit, the pavements we tread, all claim consideration in the light which chemistry affords.

In the service of sanitary science, chemistry has an educational office to fill. The undiscerning public do not appreciate the nature of chemical action, nor realize that it results in a complete change of properties of the reagents. Hence the carelessness of many about putting samples of water intended for analysis into clean vessels, and the prejudice against such products as glucose, because "vitriol" is used in manufacturing it, and oleomargarine because made with *aqua fortis*.

Nowhere more than in sanitary matters is a little knowledge a dangerous thing. The uninformed generally have some bugbear to make life a burden to them. Now it is *microbes* or *bacteria;* yesterday it was sewer gas, or perchance the adulteration of food.

Many of the notions regarding the detrimental effect of these things, arise from lack of knowledge. Not all microbes are deleterious. Chemistry fails to detect poison in sewerage. So-called adulterations of food are not always, perhaps not usually, unhealthful.

The investigation of existing evils is an important service to public health. We can hardly, for example, bring the charge of extravagance against the investigation of *The Lancet* into the character of the articles of food sold in London.

Chemistry may suggest practical remedies for existing evils. Factories which occasion detriment to public health may, in some cases, be suppressed, but unless recently established this course can seldom be pursued. Especially with reference to *chemical* trades or *chemical* nuisances, it is for *chemistry* to say what is practicable.

Of the chemists who have interested themselves in the public health we may note Lavoisier, Guylon de Morveau, Fourcroy, Berthollet, Chevreui.

More recent workers are, Frankland investigating river pollution, Schutzenberger devising methods of determining oxygen dissolved in water, Mallet studying methods of water analysis, Remsen the organic matter in the air, and Leeds the effect of charging water, used as a domestic supply, with air.

Pettenkofer approached the matter from a physiological standpoint, and his students in the Munich Laboratory have brilliantly shown how chemistry can aid both physiology and hygiene. His method of determining the amount of carbonic acid in air remains to-day substantially unaltered.

Robert Angus Smith devoted almost his entire life to the pursuit of sanitary chemistry.

Although printed directions are much better than in

Digitized by Google

former years, the problems of sanitary chemistry are not yet solved.

Numerous chemists have analyzed the atmosphere with reference to its main constituents, more recently investigating the changed relation of oxygen and nitrogen under changed barometric conditions. But while we know so much, who knows what is the bearing on the health of the community of the slight natural variations to which the atmosphere is subject? How far do they contribute to the healthfulness or so-called malaria of a locality? Although the passage of carbon monoxide through heated iron is practically of no account, who can tell us the composition and the amount of the gaseous *somethings*, which, escaping, make the air of a house heated by anthracite so different from that of one heated by wood fire?

All the methods of examination of water heretofore employed are open to criticism. Some believe that the wholesomeness of water can only be decided by *biological* examination.

The *materies morbi* which convey specific disease is generally believed to be organized, and the method of analysis consists in mixing a measured volume of water with gelatine and counting the number of colonies developed after a certain time. The microbes may be further studied by high powers of the microscope, and by staining media, and their pathogenic effects tested on animals; but this is not usually done. The water is simply graded by the number of microbes found. We cannot believe that these methods will for a long time supplant chemical analysis. In order that they should do so, it must be established that the evil effects of impure water are due to them. The mere proportion of bacteria found cannot be a criterion. When biological examination of water has been placed on a firm basis it will be necessary to discover what chemical characters belong to an impure water.

Much chemical work remains to be done in the matter of the pollution of streams, especially by sewage. The natural purification of streams is admitted to be a fact, but its extent is not settled, nor the effect of different agencies. We must study the effect of oxygen in dilute solutions of the variety of chemical substances in the complex mass known as sewage.

Recent years have seen increased activity in investigating adulteration of food, and more stringent laws to prevent adulteration.

In Germany, since the law of May 14, 1879, most large cities have established laboratories for food analysis, which are at the service of the public, either gratis or nearly so. In Austria, the examinations required by the law of April 30, 1870, are carried out in existing laboratories. In France are several laboratories, that of Paris having more than twenty-five chemists, but its methods and standard have been criticised. In England the Sale of Food and Drugs Act (1875, amended 1880) called for appointment of public analysts throughout the kingdom.

In this country laws against adulteration exist in several States, and in New York, Massachusetts, and New Jersey they have been made more stringent on account of the popular feeling in 1878–79. No laboratories have been established, however.

In this country individuals seldom care to prosecute, and the laws must be enforced by official inspection. Existing laboratories are probably sufficient, and it is advantageous to secure coöperation among chemists as is now done in New York. There is an American Society of Public Analysts meeting in New York and Brooklyn.

The chemist has to solve many problems of special sanitary importance. The greater bulk of this work is done in Germany.

One of the first independent laboratories established for the investigation of agricultural, pharmaceutical, and physiological chemistry is at Dresden, under Dr. H. Flack, and was opened in January, 1871. The expenses are borne by the State. Among the subjects investigated are the various methods of water and food analysis, methods of rendering combustible material uninflammable, the composition of the ground water and the ground air in various localities, including cemeteries, the composition of the air in buried coffins, or in the neighboring ground, and the character of the water draining therefrom, the porosity of soils to water and air, the pollution of streams, the effect of arsenical paper hangings; studies have also been made on disinfection and disinfectants, on natural and artificial ventilation, and on the ventilation of particular buildings. In our own country many such matters have also been studied. The State Board of Massachusetts led the way; others have followed.

The laboratory of Berlin deserves mention, being devoted to the solution of various hygienic problems.

The laboratory of the Observatory of Montsouris, in Paris, closes this incomplete list. It was established in 1871, for the study, principally, of meteorology in its bearing on agriculture and hygiene. Regular chemical determinations are made of the ozone, carbonic acid, and ammoniacal and organic nitrogen in the air; in the meteoric waters. Estimations are made of the ammoniacal and organic nitrogen, of the nitrogen in the form of nitrites and nitrates, and of the organic matter oxidizable by permanganate of potash.

An essential preparation for this work is thorough knowledge of chemistry and physics. The Massachusetts Institute of Technology has equipped a laboratory for special study in reference to sanitary chemistry.

Although we use the term "sanitary" chemistry, we must not lose sight of the fact that the underlying principles are the same as in all chemistry.

Courses of sanitary engineering are being opened in various technical schools. It would be well to give students in these courses some instruction in chemistry, with special applications, in order that they may have an intelligent idea of what questions to submit to the chemist, and how to understand the results.

(*To be concluded.*)

NEW YORK.

(*From our Special Correspondent.*)

THE CONCOURS SYSTEM is about to be tried in this city, its inauguration being at the College of Physicians and Surgeons, where it is proposed that an adjunct to the Professor of Surgery shall be appointed. Three of the brightest young surgeons of this city, Drs. W. T. Bull, Hall, and Halstead, it is said, will be competitors.

Digitized by Google

THE ADVERTISING ABUSE that THE NEWS has editorially noticed and condemned, has again cropped out in the form of a highly colored report of a "new and terrible operation performed at the Charity Hospital." The procedure was simply abdominal section for cancer "weighing twelve ounces." The most minute details of the operation were published by several newspapers, and pains must have been taken to secure the attendance of their various reporters. It is only a few months ago that one individual secured a puff upon the merits of a revolving knife, and if this thing goes on we shall rival the patent medicine men in our methods.

THE CARTWRIGHT LECTURES.—It is reported that the coming Cartwright Lectures will be delivered by Dr. Osler. The high character of this gentleman's London lectures presages a great improvement over anything we have had here before.

THE HOBOKEN DRUGGIST'S MISTAKE.—The occurrence of a druggist's mistake in Hoboken, whereby two young women lost their lives through the substitution of ten grains of the sulphate of morphine for quinine, has given rise to a great deal of newspaper discussion. Several druggists who have been interviewed call attention to the looseness of prescription writing and the tendency to abbreviations. Though it seems, upon the part of physicians, almost too much to expect an enforced preliminary classical course in these days when men study medicine as they would plumbing, it certainly should be required that they be made to acquire sufficient knowledge of Latin to order medicines. Perhaps the labor-saving formulæ of prepared pills and other medicines are responsible for this.

HOW THE DOCTORS TAKE THEIR HOLIDAY.—The number of medical men who have passed their summer in Europe is not so large as usual. Drs. Agnew, Otis, and a few others have established a little summer medical colony at Montauk Point, Drs. Jacobi and Gillette go to Lake George, Dr. Thomas to Southampton, Drs. Cleveland and Robinson to Newport, while Drs. Dawson, Loring, McLane Hamilton, and others, take to their yachts. Drs. Sands and Peabody go to Halifax, and a number of the elderly men stay in town.

SMALLPOX IN MONTREAL.—There were twelve deaths from smallpox in Montreal on Saturday, fourteen on Sunday, and twelve on Monday.

The Central Provincial Board of Health met on Monday at Montreal, and decided to issue circulars to all the municipalities in the Province, ordering them at once to establish local boards of health. The representatives of the Montreal City Council announced that it was the intention of that body to erect a permanent contagion hospital containing 200 beds. In the meantime a temporary ward would be begun on Tuesday, in connection with the present smallpox hospital, to contain fifty patients. This brings its capacity up to 119 beds.

Ten physicians will be appointed at once to begin house-to-house vaccination.

The officers of the New Hampshire State Board of Health, who have returned from Canada, express the highest dissatisfaction with the inefficiency displayed by the City Government of Montreal in its dealings with the smallpox epidemic. They say that immediate action must be taken if New England is to be spared from the disease. The running of passenger cars through from Montreal by way of Concord was stopped on Monday, and all through passengers will be transferred at or near the boundary line. The subject of stopping all trains beyond the line is said to be under consideration by railway officials.

President Connor, of the State Board of Health, holds that the United States is the only power that can establish an effectual quarantine between Canada and New England.

PUBLIC OPINION ON THE CONGRESS OUTLOOK.—The outlook for the Congress is critical, and the honor of the medical profession of the United States is involved in the success of that Congress. Therefore, those who have been intrusted with the preparation for it should weigh well every official act of theirs. Too many mistakes have already been made. The present Committee cannot afford to add to that number, any more than the profession at large can afford to have it done. Broad, liberal ground should be taken by the Committee. It has the experience of the eight preceding congresses to guide it. Surely the experience gained in them should greatly aid the present committee, and the advantages of that experience should not be lost or ignored.

In the organization of the Congress, the same rules should govern in the next that have obtained in the past. No distinction should be made between the foreign and American members. The fact should be distinctly kept prominent that it is not a delegated body. It has not been in the past; there is no valid reason why there should be any effort to make the next one such. There should not be two or more classes of members. All must meet on the same plane—with equal privileges—equal duties—and equal responsibilities. Let all local ethical questions be eliminated. The foreign representatives expect and demand this, and such is their right. There may be honest differences of opinion, in our own country, on certain points of principle and policy, but there can be no valid reason for thrusting them, or their effects, upon foreigners who may come here. Sight should not be lost of the fact that science and humanity are the objects for which these congresses convene, and that all matters of selfishness and partisanship should be subordinated thereto.

As our faith, as a profession, was pledged, when our invitation was accepted, to do all in our power to make a success of the Congress, we cannot do less. Everything that might conflict therewith, and diminish the prospect of such success, must be kept in abeyance.

For the official positions—whether the most prominent or the subordinate ones—only representative men should be selected. Much of the success or failure of the Congress will depend upon the wisdom and the fairness of the action of the committee at its coming meeting. We hope that it will be such that there may be no occasion for vain regret.—*Chicago Medical Journal and Examiner*, September.

After the utter failure of its efforts at Chicago, and in view of the disturbance its action has brought about, we have felt that this Committee was in duty bound to decline any further participation in the work of reorganization of the Congress. Having so signally failed at Chicago we are unable to understand upon what grou it can hope to be more successful in its future under

Digitized by Google

ings. From a circular which has recently come into our possession we fully recognize the part which this new Committee will attempt to perform. Bracing itself up under the issues of the "Code" this Committee will urge the reorganization of the Congress upon this platform.

But after all, this cry of the "Code" has a tamer significance than a casual observation would indicate. We have already noticed the fact that the "Code" issue has been repudiated by the very best scientific minds in this country and in Europe. The present Committee has caught on to this issue as a possible popular wave to ride into high official position and authority.

Indeed, the whole outlook for the Congress is utterly ridiculous and absurd. The profession in this country may well cry shame over its present humiliation. Who can look on and not blush over such an arrangement as is proposed by our National Medical Association in honor of a great and influential body of scientific workers?—*Maryland Medical Journal*, September 5, 1885.

PORTRAITS OF DECEASED SURGEON-GENERALS.—Judge Maynard, Second Comptroller of the Treasury, in passing on the accounts of J. O. Skinner. Assistant Surgeon and Acting Medical Storekeeper, U. S. A., has disallowed three vouchers, aggregating $505, for portraits of deceased Surgeon-Generals of the army, with their frames, which were certified by Surgeon Huntington, Curator of the Army Medical Museum, and approved by the Surgeon-General. He says that without regard to any irregularities which may exist in the method of making these purchases, he does not think the accounts for them can be allowed on the proofs presented.

It is sought, he says, to make them chargeable to the Medical Museum appropriation for 1883, under the following provision: "For the Army Medical Museum and for medical and other works for the library of the Surgeon-General's office, $10,000." He holds that the money thus appropriated can only be lawfully expended for works relating to medical science or illustrative of the anatomy of the human system, or which will be serviceable in the treatment of diseases, and adds that, "if it is desirable that the walls of the Museum should be adorned with the portraits of the distinguished men who from time to time have presided over the administration of the Medical Department, Congress should provide for such an expenditure in clear and unmistakable terms.

"The Medical Department is but a Bureau of the War Department, and if money, which was designed for the maintenance of the Medical Museum, in the absence of express authority can be applied to purchases of this kind, then no objection could be successfully interposed to the expenditure of this appropriation for the purchase of portraits of the different Secretaries who have presided over the War Department, or of the Generals of the army, and of the President, who is its Commander-in-Chief. It is the safer rule to limit all expenditures under such appropriations to the specific object for which they were intended, and any transgression of the rule might lead to the establishment of a vicious precedent."

NOTES AND QUERIES.

THE AMERICAN BIBLIOGRAPHY OF PHYSIOLOGICAL OPTICS.

PROF. H. D. NOYES, of New York, sends for publication the following letter from Dr. Kœnig, assistant of Professor Helmholtz, in Berlin, which opens the way to American authors to receive due recognition in the pages of the book which is the great classic on the subject of physiological optics.

BERLIN INSTITUTE OF PHYSICS, August 6, 1885.

DEAR DR. NOYES: If I remember rightly, I told you at our last meeting, which I recollect with great pleasure, that a new edition of the *Physiologische Optik* of Professor Helmholtz was being prepared. At present the work of printing has begun. The bibliography will be printed last, and in a separate chapter. It is to be enlarged, and to be brought up to the present time. At the request of Professor Helmholtz, I have taken charge of this part of the work. On account of the enormous increase of the literature of physiology during the last twenty-five years, it is very difficult to make it complete. In order to be as thorough as possible, I have published a request asking authors to favor me with a notice of their publications relating to physiological optics. This has appeared in several French and German ophthalmological journals. Would you have the kindness to procure the insertion of a similar call in some of your American journals? My address, to which letters may be sent, is Dr. Arthur Kœnig, No. 16 Weire Wilhelm Strasse, Berlin.

Any communications on the above subject will place me under great obligations. Most sincerely yours,

ARTHUR KŒNIG.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 1, 1885, TO SEPTEMBER 7, 1885.

MAGRUDER, D. L., *Lieutenant-Colonel and Surgeon.*—Granted leave of absence for fifteen days—*S. O. 201, A. G. O.*, September 3, 1885.

MIDDLETON, PASSMORE, *Major and Surgeon.*—Assigned to duty as Attending Surgeon at these headquarters, vice Major J. V. D. Middleton, Surgeon, hereby relieved.—*S. O. 131, Department of the Missouri*, August 28, 1885.

GIRARD, ALFRED C., *Captain and Assistant Surgeon.*—Assigned to duty as Post Surgeon at Boise Barracks, Idaho Territory.—*S. O. 142, Department of the Columbia*, August 22, 1885.

KANE, JOHN J., *Captain and Assistant Surgeon.*—Upon expiration of his present leave of absence, to be relieved from duty at Willet's Point, New York Harbor, and to report to Commanding General Department of Texas for assignment to duty.—*S. O. 201, A. G. O.*, September 3, 1885.

BANISTER, JOHN M., *Captain and Assistant Surgeon*—Assigned to temporary duty at Camp of Competitors at Creedmoor, N. Y., arriving not later than September 4, 1885.—*S. O. 58, Division of the Atlantic*, August 31, 1885.

RICHARDS, CHARLES, *Captain and Assistant Surgeon.*—To be relieved from duty in Department of the East, and to report to the Commanding Officer at Willet's Point, N. Y., for duty at that station.—*S. O. 291, C. S., A. G. O.*

KENDALL, WM. P., *First Lieutenant and Assistant Surgeon* (recently appointed).—To report in person to the Commanding General Department of California, for assignment to duty.—*S. O. 201, A. G. O.*, September 3, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING SEPTEMBER 5, 1885.

STEWART, HENRY, *Surgeon.*—Leave of absence extended one year from October 15th, with permission to remain abroad.

STEELE, JOHN M., *Passed Assistant Surgeon.*—Detached September 1st from Constellation, and report for duty at Naval Academy, Annapolis, Md.

BRIGHT, GEO. A., *Surgeon.*—Detached Sep. 1st from Constellation and await orders.

DICKSON, S. H., *Passed Assistant Surgeon.*—Ordered to Naval Academy, Annapolis, Md., as relief of Passed Assistant Surgeon A. A. Austin.

FITTS, HENRY B., *Assistant Surgeon.*—Detached from Coast Survey Steamer "Gedney" and wait orders.

AUSTIN, A. A., *Passed Assistant Surgeon.*—Detached from Naval Academy, Annapolis, Md., and ordered to Coast Survey Steamer "Gedney" to relieve Assistant Surgeon H. B. Fitts.

ORIGINAL LECTURES.

DYSMENORRHŒA.

A Clinical Lecture delivered at the Post-Graduate School of New York.

BY A. J. C. SKENE, M.D.,

PROFESSOR OF GYNECOLOGY TO THE LONG ISLAND COLLEGE HOSPITAL AND POST-GRADUATE SCHOOL OF NEW YORK.

(Reported by Edward Develin, M.D.)

GENTLEMEN: To-day I wish to bring specially to your notice the subject of dysmenorrhœa, illustrating my remarks with such cases as I shall present for your personal examination.

Our first patient is a young girl, seventeen years of age, unmarried, who commenced to menstruate when she was sixteen. She has since that time always been regular in her menstruation, the flow lasting from four to five days. During these periods she always suffers from pain, which continues during the flow. She menstruated last, just one week ago. She has no special difficulty with her urinary organs. She has had constant but not very free leucorrhœa, with pain in the left side; bearing-down pains, continuous headache, and also pain extending down the left leg; there is also tenderness of the left ovary. When the pain is most severe, the breasts, she states, ache very badly. The pain in the head, I should state, is almost always upon the right side. All of these symptoms are increased just previous to menstruation.

You will remember that the patient has just passed the age of puberty, and from the symptoms given us in connection with this fact we should be led to believe that the sexual organs are not sufficiently developed to perform their natural functions; or, in other words, she may be suffering from an arrest of development of the sexual organs, or perhaps a malformation, or both.

One point which strikes me very forcibly is her nervous symptoms. You are, of course, aware that much has been said and written about the disturbances of the nervous system due to a reflex irritation of the sexual system. Neurologists are apt to claim such cases as due to the nervous affection; that is to say, that the primary difficulty arises in the nervous system, leaving out of account to a large extent the sexual system. Gynecologists, on the other hand, are perhaps apt to refer the difficulty to the sexual organs, and regard the nervous affection as secondary, or a condition induced by reflex action from irritation of the sexual organs; they perhaps view the case entirely through the speculum.

Now, I have tried to be impartial, and to give to the nervous system its due, and also to share the responsibility of the derangement with the sexual organs. I have investigated carefully by clinical observation, and endeavored to decide how much of the disturbance is due to a malcondition of the nervous system primarily, and if the sexual irritation was not secondary. The neurologist, by his experience with nervous diseases and accurate means of investigation, might make a diagnosis with facility, which, perhaps, might puzzle the gynecologist in his everyday practice; hence, in obscure cases, it is well to seek the counsel of a neurologist. During my observations, however, one rule has been quite reliable as a guide in uterine diseases complicated with nervous troubles, viz., Which appeared first, the nervous symptoms or symptoms of sexual derangement? Did this patient first manifest symptoms of distress in the head and limbs, or were symptoms of distress noticed in the pelvic region, in the sexual organs. It is quite fair to suppose that the symptoms which appeared first indicate the primary lesions, and such I have found to be almost invariably the rule; but, like all rules, there are rare exceptions.

In this case, her local trouble appeared first, followed by hemicrania, pains in the body and left leg. These appeared some time after she had been suffering from dysmenorrhœa. So I think that we are perfectly safe in saying that her nervous disturbance is reflex, the nervous symptoms being always aggravated during menstruation.

Menstruation, when performed by perfectly normal sexual organs, is not associated with any *marked* disturbance. On an average, forty-five per cent. of women suffer from some disturbance, the remaining fifty-five being free from distress. So that when any general symptom is very decidedly aggravated during the menstrual period, we take it as positive or presumptive evidence that it arises from some derangement of the sexual organs. More than that, if a nervous symptom which appeared at first only at the menstrual period, eventually becomes continuous, we would infer that it is reflex. Instead, therefore, of directing our treatment to the nervous system, we at once direct our attention to the sexual system, where we know that a difficulty exists, and if our diagnosis be correct, the disturbance of the nervous system will abate as the local trouble is relieved. If relief does not follow our local treatment, this shows that either the nervous symptoms arise from a disease *per se*, or else the nervous trouble was at first reflex but in time became centric and continued after the cause was removed. The rule, however, which I have just stated as to the primary lesion in these cases, is quite reliable for purposes of diagnosis.

This patient is suffering from an anteflexion of the body of the uterus, with a partial anteflexion of the neck, the uterus being also a little below the normal elevation. I have frequently stated that we often meet with this anteflexion of the neck owing to an imperfect invagination of the cervix. As the uterus settles down into the vagina at a certain period of life, the posterior wall in these cases goes down faster than the anterior, making the length of the posterior portion of the cervix abnormally longer than the anterior. This shortness anteriorly, you can then readily understand, has a tendency to draw the cervix forward, and hence is one of

Digitized by Google

the causes of anteflexion of the cervix. I find on examination, also, a marked tenderness of the right ovary; this may be the cause of the pain extending down the right leg of which she complains, the irritation at the ovary having extended to the sacral plexus of nerves. In relation to the headache here existing, we all know that nervous exhaustion from over-functional activity of the sexual organs tends to develop sick headache, and that it is also an established fact that functional derangement of these organs will produce this pain in the head, and we also know that this derangement is in some way related to epilepsy. We must not, however, attribute every sick headache to this cause, any more than we would say it is the cause of every case of epilepsy.

Now as to the management of this case. We shall treat it as an ordinary anteflexion, restoring the uterus to its normal position and retaining it there with an anteversion pessary. Dr. Emmet, in a case like this, converts it into a simple anteversion by pushing the cervix backward, so that the uterus is made straight.

Let me say here that that treatment will answer in a case like this, because the patient is not suffering from any disturbance of the bladder. We must remember, however, that in many cases of anteversion we have frequent and painful urination, which is a source of great discomfort to the patient. In that class of cases, therefore, if you were to follow out Emmet's method as I have just stated, you might, perhaps, relieve the dysmenorrhœa, but you would certainly aggravate the cystic trouble.

We should always bear in mind, in these cases of malformation, that we have both hyperæmia and hyperæsthesia of the parts; so that the uterus, owing to its irritable condition, will not perform its natural functions without complaining. As a rule, I think that hyperæmia always accompanies these malformations, but I presume that it is due to the imperfect functional action primarily.

In dysmenorrhœa we have one class of pathologists who tell us that the difficulty arises from some obstruction of the cervical canal caused by the flexion. Another class will tell us that the flexion has nothing to do with it; both classes bringing forward cases to prove their theory.

I endeavor to harmonize these statements in this way. I believe you may have dysmenorrhœa from stenosis and also where stenosis does not exist. I believe that in those cases where flexions exist, if the physiological hyperæmia at the time of menstruation is not sufficient by its engorgement to straighten the uterus and render the canal free from occlusion, that you will have dysmenorrhœa. This form of dysmenorrhœa, therefore, is due to mechanical causes, and in these cases the pains will be intermittent like miniature labor pains, the flow being more profuse after the pains; whereas, the pain which is marked by a dull aching feeling, continuing through the entire flow, I believe to be due to hyperæmia and hyperæsthesia of the parts, and not due to obstruction from true stenosis or flexion, even though the latter may exist. You can readily understand how either one of these conditions may cause dysmenorrhœa; and yet we meet cases in which there are hyperæmia, hyperæsthesia, and malformation, and no dysmenorrhœa occurs.

When we are not positive as to which of these conditions produces the dysmenorrhœa, we are set at rest in regard to the treatment. Whether it be due to one or the other, we should endeavor to remove both. Straighten the uterus and relieve the hyperæmia and hyperæsthesia as indicated. So that while we may be puzzled to know which is the first link in the chain of the pathology of the disease, we have no need to doubt about the treatment. Therefore, if you find a malformation, do not be content with removing that, but at the same time treat the accompanying engorgement and hyperæsthesia in the same manner as you treat other hyperæmic conditions of the uterus.

I believe that much of the good that comes from Sims's operation of dividing the cervix is not so much due to the operation, but the relief of the hyperæmia. The free hemorrhage and rest in bed after the operation do much toward relieving these tender, irritable states of the uterus. And when the woman gets up and assumes her regular vocations, I believe that unless she becomes pregnant the same difficulty will recur. I think the failures which occur in treating dysmenorrhœa are principally due to neglect on the part of the physician to treat both the malformation and the derangements of circulation and innervation *at the same time.*

Now, in the case before us, while we are fully considering our local treatment, we must remember that the patient is only seventeen years of age; there is, therefore, yet hope of building up the development of the sexual organs, in order that their functions may become normal.

Much has been said and written in relation to the development of the sex in relation to the development of the sexual organs. Some who are extremely orthodox believe that all a woman has to do in order to become perfectly developed, is to wear low-heeled shoes and abandon the use of corsets. One will say the arrest of development is due to wearing corsets; another, to using high-heeled shoes; others, again, attribute it to mental aspirations and high mental culture. A rational scientist, however, takes a broader view of the whole matter, and will state that either or all of these will tend to arrest development. We know positively that it is essential to the woman's well-being that the sexual organs should be perfectly developed in order that they may perform their natural functions perfectly. We also know that we can do most to secure their development through their general organization. Instead, therefore, of giving our attention exclusively to the cure of malformations, hyperæmia, etc., let us turn our attention also to the improvement of general nutrition to further the desired development. As the sexual organs are dependent upon the general organization, we can stimulate them through the nutritive system. Therefore give such patients good air, good food, not too much rest, but good hygienic surroundings.

Our second patient is twenty-three years of age, and has been married eight months. She has suffered severely all her menstrual life from dysmenorrhœa, although her menstruations have always been regular.

During the last eight months, that is to say, since she has been married, her dysmenorrhœa has been increased. This is an important point for us to bear in mind, as there are certain cases of uterine disorders in which a change in social relations effects the most satis-

Digitized by Google

factory results. On the other hand, however, there are cases in which this change effects the most disastrous results.

The question as to the results of marriage in certain persons afflicted with uterine disorders will often be put to you by the heads of families; it is, therefore, of great importance that you give a correct answer to their interrogations, as such answer may involve the happiness of two persons, at least. There are certain affections of the uterus, such as slight hyperæmia or leucorrhœa, which will not be increased or aggravated by matrimonial relations. Then, again, there are other affections which are invariably made worse by sexual intercourse, and the case now before us I judge to be one of these latter.

If, now, you are asked whether it will be well for a woman to marry whom you know is suffering from some organic disease, it will be wiser for you to say that a matrimonial alliance will be likely to increase her uterine difficulty. If, however, the case be one of mere functional disturbance, it may be improved by such relations. You cannot be too particular on this point, and should be on your guard against making an error in your answer.

This patient presents to us a history which indicates that there is in all probability organic disease, or malformation. When from the very outset of the menstrual function dysmenorrhœa has been the rule, we may be almost certain there is some organic lesion. Your advice then should be: don't marry.

I will now make an examination in this case, and give you the physical signs as I obtain them by the touch.

I find here a malformation in the relation of the cervix with the vagina, the uterus being also low down in the pelvis. I find there is no invagination of the anterior wall of the cervix; it is, however, invaginated slightly posteriorly, but not much. There is here a curious condition of things, being more marked than I have ever seen before. The vagina, anteriorly, comes off in a perfect line with the cervical canal. As I pass my finger along the anterior vaginal wall it comes into contact at once with the os externum; the anterior wall of the cervix being so very thin, there is not the slightest invagination. We have here also a marked anteflexion of the cervix, due, I have no doubt, to this imperfect invagination and arrest of development. In speaking of the development of the sexual organs, I have told you that at the end of the primary development the vagina and cervix simply meet; there is at that time no invagination of the cervix. But during the secondary development the uterus settles down into the pelvis and invagination occurs. Sometimes this process is arrested, owing, perhaps, to some malnutrition of the part, or some inflammatory action. Such an arrest of development has undoubtedly occurred in this patient, and the same I believe to be the cause of her dysmenorrhœa, aggravated by the hyperæmia which is developed sooner or later by such malformation.

As I now place the woman in Sims's position, and pass the sound into the cervical canal, it passes back towards the hollow of the sacrum, and when I reach the internal os I am compelled to revolve the sound in order that it may reach the fundus, thus proving the physical signs as obtained by the touch to be correct. On measuring the length of the body I find it to be but one and one-half inches in length. We cannot, then, with this history and these physical signs, have any possibility of doubting the cause of her dysmenorrhœa and sterility.

Now as to treatment. Our first idea would be to correct this malposition of the cervix, it being the most marked. That we can do by performing Sims's operation, and, perhaps, in that way relieve her dysmenorrhœa. This operation consists in dividing the posterior wall of the cervix, by this means changing the direction of the cervical canal so that it would be almost or quite straight. In this way you cure one malformation by producing another; but you relieve your patient, if not permanently, for the time being. By performing this operation we can sometimes cure the patient of her sterility and also her dysmenorrhœa. The dysmenorrhœa, however, will recur again if she does not become pregnant; for this reason the operation often fails because we do not select our cases. If you have a patient with a large, well-developed body of the uterus, and one who menstruates normally and freely, except that she has dysmenorrhœa, having no other trouble but this forward flexion of the cervix and imperfect invagination, we might expect to accomplish much by Sims's operation. But in this case I am sure it would prove a failure, as the whole uterus is undersized, and I doubt whether she could ever become pregnant, or carry on gestation if she did. We might overcome the dysmenorrhœa for the time being, but I do not think we could cure her sterility. I shall, therefore, decline to operate, as I do not think any permanent relief can be obtained.

I have said that if after the operation the woman does not become pregnant her dysmenorrhœa will return. This, perhaps, needs an explanation. The reasoning is simple enough. In all of these operations we have resulting scar tissue. If the cervical canal be only enlarged at the time being, mechanical factors not being brought into play to maintain the enlargement secured, we have this cicatricial tissue contracting down and shortening the cervix with partial occlusion of the canal taking place in a few years. In some cases the intrauterine stem is passed into the canal to keep it widely open, but this is too frequently of itself a source of great danger and irritation.

If this woman were but seventeen or eighteen years of age we might, by performing Sims's operation, afterward introducing the stem pessary, hope to cure her of her dysmenorrhœa, so that she would become more developed and afterwards bear children. But at twenty-two years of age we cannot hope for this.

In our present case we can relieve the hyperæmic condition there existing, and can also cure the catarrh of the mucous membrane; we can also dilate the cervical canal. She might by some accident become pregnant; we cannot always be positive in these cases.

I know of no operation in uterine surgery which has been so much abused as this operation of Sims's just spoken of. Division of the cervix has been so often performed for all kinds of malformations that it has given rise to rather an energetic discussion among gynecologists. I am sure, from observations during a long period, and giving due weight to both sides of the question, that the case now before us is the limit of the

Digitized by Google

desirability of the operation. By this I mean, when forward flexion of the cervix *exists alone* we may hope for the best results from the operation.

We should, however, bear in mind that the object of this operation is to relieve dysmenorrhœa and sterility, and if it does not relieve the sterility, the patient gains nothing in the long run, but may in time be the worse for it. If the operation makes pregnancy possible, the development of the uterus during gestation will cure the original arrest of development; but if pregnancy does not occur, the operation is but a mutilation added to a deformity, and the two are worse for the patient than the original malformation alone.

SOME THERAPEUTICAL USES OF PILOCARPIN

BY A. B. ISHAM, M.D.,
OF CINCINNATI, OHIO.

INSOMNIA OF ALCOHOLISM.

A LITTLE over a year ago I had a case of uræmic convulsions in a vigorous male subject, in which the convulsive action was quieted by venesection and the hypodermic injection of morphia. In the semi-comatose condition succeeding, he was seen by Dr. J. C. Mackenzie as consulting physician. A very active delirium followed, and pilocarpin muriate was employed to promote the elimination of urea. The tranquillizing, soporific influence of this alkaloid was so marked as to suggest the probability of its usefulness in alcoholic insomnia, in which an agent capable of producing sleep without specific action upon the nervous system, at the same time inducing rapid excretion of alcohol, and without any of the intoxicating properties of the narcotic drugs so universally resorted to in this condition, would appear to be a special desideratum.

It was only a short time until an opportunity occurred to test its practical value. This presented in the case of a plethoric individual who was accustomed nightly to woo "nature's sweet restorer" with a pitcher of beer. In consequence, a gastric catarrh had developed, for the relief of which whiskey in copious and frequent draughts was the remedy chosen. This in turn had brought on the "horrors," and the common enemy of mankind was but poorly concealed in the background. The patient had already, for a day or two before I saw him, been given chloral and potassium bromide in scruple, half drachm, and drachm doses without any beneficial effect. It made him wilder, and more intractable, provoking a mental and physical state of disquietude and torture beyond what the whiskey itself might have been justly responsible for. He was retching every few minutes, eyeballs bloodshot, protruding and glaring, countenance suffused and bloated, hair dishevelled, howling and cursing—the picture of a tormented wild beast, rather than of a human being. One-third of a grain of pilocarpin muriate (Merck's) was administered hypodermatically, and a large mustard plaster placed over the epigastrium. In ten minutes copious perspiration, with free salivation ensued, and slumber succeeded, lasting continuously for five hours. The patient awoke quiet and *sober*. Ice water was asked for and given. Short, restful naps were taken. No desire for liquor was expressed, and the importance of abstaining from it altogether was urged and acquiesced in. Milk and lime-water, buttermilk and beef extract were given *ad libitum*. The gastric catarrh was successfully treated with resorcin, gr. vij *ter in die*. The catarrhal trouble in this case may have been ameliorated by the pilocarpin's unloading the turgid capillaries of the stomach, but in other cases of drinkers' dyspepsia, in which pilocarpin was not administered, resorcin in my hands had proved so specific in its action that I did not venture to withhold it in this instance. Pilocarpin was continued in one-third grain doses for two more successive nights, when cure was complete. He refrained altogether from the use of liquors for one month, a practice he had not observed before for years. During this period of abstention he ate well, slept well, and, as he himself stated, never felt better in his life.

Unfortunately for himself he was not in political affiliation with the prohibition party, and being an ardent patriot, could not withstand the blandishments of his party associates. He lapsed again, again stood upon the ragged edge—and again was brought back to self-control and duty by pilocarpin. He was also strictly abstemious after the second attack. Once more official decapitation caused him to lose his balance; pilocarpin restored it, and he is to-day leading a perfectly sober life.

The remedy has been tried with as signal success in two other subjects of alcoholism. The history of such cases is so familiar to the profession as to make detail unnecessary. One was an habitual drinker, with occasional excesses, and the other a "spreer," with intervals of abstention.

The *sobering* properties of pilocarpin are remarkable. After the sleep the patient arouses perfectly rational and subdued—a consummation of no little importance, as all know who have to treat the victims of alcohol, since it renders them amenable to moral influences. The transformation wrought in the physical appearance is almost marvellous. The tense, red, bloated countenance, the bleared congested eyes, and general repulsive facial aspect pass away. The skin looks pale, clean and soft, the features calm and easy, the eyes clear or with only a slight yellowish tinge. Clothed in such an innocent guise the subject of a recent debauch might easily deceive even an expert.

There are three ways in which pilocarpin doubtless exercises a therapeutic influence in alcoholism. 1. By lowering the cerebral blood pressure. 2. By eliminating alcohol. 3. By increasing the absorption of oxygen.

The throbbing carotids, the suffused face, and congested eyes in acute alcoholism all bespeak an increase of blood pressure in the cerebral vessels. It goes without saying that an increase of irritability of nervous centres is consequent thereto. The rapid and enormous cutaneous transpiration and salivary outflow occasioned by the exhibition of pilocarpin diminish the blood pressure, and must lessen nervous excitability in proportion to the extent to which it was enhanced by the previous pressure.

Digitized by Google

Alcohol is carried off through the lungs, skin, kidneys, and general emunctory glands, while yet a not inconsiderable amount is consumed in the system through oxidation. The rapidity of elimination is in direct ratio to the activity of the excretory organs. Pilocarpin produces increased frequency of respiratory acts with much greater increase in cutaneous and glandular processes of excretion. The lowering of blood pressure, with increase in the frequency of respiration and of the heart's action, also promotes a more rapid evolvement of the physio-chemical processes upon which the combustion of alcohol depends. The excitant action of alcohol upon nervous structures is without question, and when all the means through which the agent may find external conveyance, and internal combustion are brought into most active operation by pilocarpin, the relief to overstimulated nerve tissue must be very considerable.

It has been shown by Harley and others, that ingestion of alcohol in quantity interferes with the absorption of oxygen by the blood, and Böcker and others have demonstrated that it lessens the quantity of carbonic acid exhaled. Increase of carbonic acid in the blood, beyond what should normally circulate in it, and decrease of oxygen, set up the widest range of disordered function in all tissue cells according to the disproportion in which the first element exists to the second. Therefore, the removal of alcohol from the circulation through pilocarpin, as already sufficiently indicated, restores to the blood commensurate capacity for absorption of oxygen, favors the separation of effete products, and by thus effecting a balance between tissue decay and repair, contributes to physiological rest.

LARYNGEAL STENOSIS—LARYNGEAL CONGESTION.

Last December a boy six years of age was taken with the then prevailing endemic of measles. The efflorescence over the body surface was complete, and the laryngeal mucous membrane was involved to such an extent as to produce a condition of stenosis. The temperature ranged from 102½° to 103½°; pulse rate 132; respiration frequent, harsh and embarrassed, voice husky and whispering, with a tight stridulous rasping cough, which harassed him so frequently as to have very little interval for rest. He required constant attention day and night. After the expiration of a week's sickness the temperature was 104½°; pulse 145; respiration rapid, labored and noisy, countenance pinched and anxious, the alæ of the nose following the movements of respiration, with a racking, dry, hoarse cough which came on in paroxysms every few minutes, causing the little fellow to jump up in bed, throw his arms wildly about in the air as though seeking to clutch something, while the color of his face changed to a livid hue. He wanted his mother constantly beside him. It was evident that vigorous measures for his relief must be instituted at once, and, theoretically, pilocarpin offering the best promise, it was administered in the dose of one-eighth of a grain by the mouth. Within fifteen minutes he was bathed in perspiration. Profuse salivation also resulted, and he sank into a tranquil, quiet slumber of half an hour's duration—a longer and easier sleep than he had enjoyed at any time during the whole of his illness. The temperature declined to 102½°, the pulse fell to 125, the breathing, though still rapid, was easy, the cough loose, less frequent, and but little disturbing. From this time on, his progress towards convalescence was marked and uninterrupted. A medical friend and relative who had seen the case and was cognizant of its gravity, was somewhat shocked at what he deemed hazardous experimentation, but he cheerfully accepted the result.

On the 17th of December, a contralto singer applied for the relief of hoarseness, dependent upon congestion of the larynx from cold. She had an engagement to sing in concert the evening of the 18th, which she was exceedingly anxious to fill. One-third of a grain of pilocarpin was prescribed to be taken per orem at bedtime, and crystals of potassium nitrate, the size of a small pea, to be slowly dissolved in the mouth throughout the next day. She was enabled to fulfil her engagement satisfactorily.

In the above cases the decrease in blood-volume, induced by pilocarpin, lowered the blood-pressure, relaxed the engorged vessels, reduced the swelling of the laryngeal mucous membrane through the occurrence of free secretion upon its surface, and the blockade being thus raised, natural forces were able to effect resolution without further aid.

I have made use of pilocarpin scores of times in uræmia, alcoholism, unilateral sweating, hyperidrosis, diphtheria, and membranous croup, and with the exception of sharp ephemeral pain at the neck of the bladder, and in the course of the urethra which two male patients complained of, have met with no unpleasant effects—no cephalalgia, nausea, or vomiting. It has been extravagantly extolled in diphtheria and membranous croup by some German writers, but I have found it utterly worthless in these diseases.

I have ventured to submit such little experience with the drug for the reason that its employment as yet has been comparatively limited, and consequently even meagre therapeutical records may have an interest which they would not have when pertaining to an agent in common use.

REPORT OF SOME EXPERIMENTS ON BURNING SULPHUR IN CLOSED ROOMS. MADE UNDER THE DIRECTION OF

J. H. RAYMOND, M.D.,
COMMISSIONER OF HEALTH, BROOKLYN, N. Y.

BY W. H. KENT, PH.D., CHEMIST.

ABSTRACT.

THE physical changes which sulphur undergoes in the process of combustion are described as follows in Lunge's standard work on the manufacture of sulphuric acid.

"Sulphur melts at 111.5° C. (232.7° Fahr.) and

Digitized by Google

forms a thin light yellow liquid which, on being more strongly heated, becomes darker and thicker; at 250° to 260° C. (482° to 500° Fahr.) it is nearly black, and so viscid that it does not run out when the vessel is upset; at a still higher temperature it becomes thinner again, keeping its brown color; and at 440° C. (824°F.) it boils, forming a brownish-red vapor, but it begins to volatilize before boiling.

"This is by heating out of contact with the air. When heated in the air the same changes take place until the temperature of combustion is reached, which, according to Lunge, is 260° C. (482° F.). It then takes fire and burns with a purplish-blue flame, forming SO_2 and giving out 2221 units of heat."

In our experiments a room entirely enclosed by wood was first used. The pine boards forming the walls, ceiling, and floor were generally matched, but in spite of continued calking with rags its condition as to tightness was not satisfactory; however, three experiments with burning sulphur were performed, and a part of the desired results obtained. It was then abandoned with the idea that the results with regard to the amount of sulphur which it is possible to burn in a given space would be of no value. We will call this *Room A*, and the small bedroom with plastered walls which was afterwards used, *Room B*. Room A was 16½ feet long, 8⅓ feet wide, and 11 feet high, and contained, therefore, 1512.5 cubic feet (42,831.8 litres, or 42,8318 c. metres). In one side was a window about 2 by 2½ feet; in the adjacent side nearer the floor was also a single pane of glass about 8 by 10 inches.

Experiment No. 1, Room A.

In a large tin pan holding about 12 quarts was placed an iron kettle holding 5½ quarts, and supported in the pan by an earthen plate; in the kettle were placed 6 pounds of broken brimstone and flowers of sulphur, and surrounding it in the pan were 8 litres (about 8 quarts) of water.

The kettle stood in the water, therefore, to the extent of about half its height. In the water was placed a maximum and minimum thermometer. Suspended on a line in about the centre of the room were 116 samples of various kinds of cloth, the coloring matters of which had been determined by Dr. O. Grothe. The samples consisted of:

18 samples of all wool dress-goods (Sicilian cord) dyed with various combinations of logwood black, logwood brown, picric acid, indigo carmine, and Bordeaux.

8 samples of silk dress-goods (silk cord), which were also variously dyed with Bismarck brown, nigrosine, alkali blue 2 B, Bordeaux, tropæline 3 O No. 2, and roacelline.

11 samples of domestic calicoes printed in many figures with catechu brown, logwood black, logwood blue, alizarine red, aniline yellow, and aniline blue.

12 samples of French satins also printed with aniline black, aniline yellow, alizarine red, indigo, logwood black, fiset wood, eosine, nigrosine, Bordeaux, and alkali blue.

24 samples of Scotch gingham colored with different combinations of Bismarck brown, logwood black, logwood blue, logwood brown, indigo, aniline blue, aniline yellow, alizarine red, alizarine rosa (tin salts), catechu brown, tropæline O (chrysoine), turmeric, tropæline O 4, fiset wood, and vesuvine.

24 samples of domestic cambrics variously printed with aniline blue, aniline yellow, logwood black, logwood blue, logwood brown, alizarine red, catechu brown, indigo, indigo carmine, naphthaline yellow, induline, and wood blue with chromine.

3 samples of oriental flannels dyed with induline, malachite green, and Bordeaux.

16 samples of domestic flannels dyed with Bordeaux, Victoria yellow, fuchsine, methyl violet, logwood black, alizarine red, induline, and brilliant blue (alkali blue 5 B).

Duplicate samples of each of these were retained for comparison. The sulphur was ignited with burning alcohol, and the room closed as soon as possible.[1]

At 8.30 P. M. the room was opened.

Of the 6 lbs. of sulphur introduced 5 lbs. 9 oz. were burned; the remaining 4 oz. consisted of sulphur, sulphide of iron, and impurities. Owing to the reduction of temperature, it would not in any case be expected that the sulphur would be completely consumed.

Of the 8 litres of water introduced in the pan, 6.39 litres remained; 1.61 litres were, therefore, evaporated. The temperature of the water which, at the beginning, was 71° F., had risen to 158° F.

The samples of cloth were then arranged in series by the side of the original and exhibited to a number of persons, some of whom were experienced dry-goods salesmen and were really experts in judging the qualities of fabrics. The general opinion was that as to strength of fibre, no change in any case could be discerned; that as to color, one sample of Sicilian cord, colored with indigo and induline, and one sample of domestic flannel colored with brilliant blue (alkali blue 5 B) were very slightly faded; that one sample of oriental flannel colored with malachite green was not quite so bright; that one sample of oriental flannel and one sample of domestic flannel, each colored with induline, were somewhat faded; that with the remaining 111 samples there was no perceptible change. It is also observed that among the flannels only two were colored with induline, and that these, as above expressed, were the most affected, and that the only piece of woollen dress-goods which contained induline was the one which was very slightly faded.

Experiment No. 2, Room A.

In this experiment an attempt was made to reach the limit of sulphur which might be burned in the room. 32 lbs. 5 oz. of sulphur were placed in two kettles; one kettle with 16 lbs. 4 oz. placed in the tin pan as before, was surrounded with 8 litres of water, the other with 16 lbs. 1 oz. was placed in a

[1] *Note.*—As it has been asserted that sulphur fumigations will not even kill insects, we suspended in the room, before the larger window, a wire fly-trap containing about a dozen flies, another with six or eight ants, and another with half a dozen croton bugs (Ectabia Germanica). The time necessary for killing these insects was observed through the window. All flies were dead in 22 minutes; all ants in 24 minutes; and all croton bugs in 25 minutes.

Digitized by Google

wooden tub, and around it were 25 litres of water. In each case fully one-half of the kettle stood below the surface of the water. There was also suspended in the room, the same as before, a set of samples of the same fabrics from which those before used were taken, numbered the same, and for distinction marked with the letter "Y." The thermometer was also hung before the window, the sulphur ignited with alcohol and the room closed as before.

At 9 P. M. the sulphur ceased burning. On the following day the room was opened. The sulphur fumes had escaped so that it could be entered immediately. Of the 16 lbs. 4 ozs. of sulphur placed in one kettle, 6 ozs. remained; of the 16 lbs. 1 oz. placed in the other, 9 ozs. remained; or of the 32 lbs. 5 ozs., 31 lbs. and 6 ozs. were burned. The remaining 15 ozs. consisted of sulphide of iron, sulphur, and impurities. Since the room contained about 1500 cubic feet, the amount burned was nearly 21 lbs. per 1000 cubic feet. The water surrounding the kettle was found to contain much sulphuric acid. The amount consumed was largely in excess of that required to consume the oxygen of the air; and, as the sulphur was practically all consumed, the room must be considered as not sufficiently tight for the experiment.

The amount of sulphur required to consume completely the oxygen in 1000 cubic feet of air, as found by calculation, is 15,577 lbs. Of course, the low temperature and the highly diluted form the oxygen attains would both tend in practice to reduce greatly this amount.

Vallin, in his *Traitè des Dèsinfectants* (p. 243), states that, experimentally, M. Martz was able to burn only 68 grammes per cubic metre, or about 4.2 lbs. per 1000 cubic feet; and that Czernicki was able to burn, in a large room, 300 grammes per cubic metre, or 18.7 lbs. per 1000 cubic feet. The room, in the latter case, was undoubtedly not tightly closed, as a comparison of his results with the theoretical amount will show. As to the effects on the fabrics in this experiment no difference could be noticed from that of the experiment before given. The samples of cloth in both experiments are arranged in convenient form with those of the original, and may be examined at the office of the Department of Health in Brooklyn.

Experiment No. 3, Room A.

It having been asserted that burning sulphur is not always effective in killing insects, and especially flies on the ceiling, another experiment was made to ascertain with more certainty whether flies are killed uniformly throughout the room, where the usual amount of 3 lbs. of sulphur per 1000 cubic feet is burned. To this end a window was placed next the ceiling by the upper front left corner of the room, and another by the diagonal corner of the left side next the floor. A fly trap with a number of flies was placed by each window next the ceiling and floor. Flies in traps were also placed at the upper back right corner and on the floor by the diagonal corner of the right side, one was also placed on the centre of the floor, and another on the centre of the ceiling, and one by the window in the centre of the left side. There were also a number of flies, perhaps fifty, confined loose in the room, going where they chose. An iron kettle, with 4 lbs. and 9 ozs. of sulphur, was placed in water in the large pan, the sulphur ignited, and the room closed as before. The flies next the ceiling, as observed from the window at the upper front left-hand corner were all dead in twenty-three minutes; those by the large window on the left side also in twenty-three minutes; those on the floor at the back left-hand corner were dead in fifty minutes; while some of the flies loose in the room, that had collected mostly by the small window in front near the floor, lived for one hour and forty-five minutes.

The sulphur fumes being heated evidently rose at first to the upper part of the room. The room was then immediately opened, the sulphur extinguished, and as soon as the room could be entered it was found that in all those portions of the room which could not be seen from the windows all flies were dead. It would seem, therefore, that when the flies are simply confined in a room not especially tight that they were able by the greater liberty afforded them to withstand the action of the sulphur fumes much longer than when confined to a particular locality in traps. By weighing the kettle and the remaining sulphur it was found that four pounds of sulphur were burned.

Experiment No. 4, Room B.

This room, provided with an ordinary window and door, measured as follows: 8 ft. 2 in. long, 6 ft. 2 in. wide, and 7 ft. 7 in. high, containing, therefore, 375 cubic feet. All crevices were thoroughly calked. In an iron pot were placed 16 lbs. 3 oz. sulphur. This was placed in the above described tin pan, and surrounded by nearly 10 litres of water. A maximum and minimum thermometer was hung on the wall showing a temperature at the beginning, of 76° F. In order to ascertain whether sulphuric acid would be formed, and whether the cloud of smoke arising from burning sulphur was due to the formation of this acid, or to sublimed sulphur, or both, a pane of glass 7 x 12 in. was thoroughly cleaned, wiped dry with a clean cloth and supported horizontally in the middle of the room by a clean glass support. The sulphur was ignited, the door thoroughly calked, and it being Saturday, P.M., it was left to take its course. The sulphur continued to burn for about 12 hours. When opened on Monday the atmosphere was not endurable, The temperature of the room had risen to 122° F. (50° C.), as shown by the maximum thermometer. Of the 16 lbs. 3 oz. sulphur introduced 2 lbs. 2 oz. had been burned, or at the rate of $5\frac{3}{8}$ lbs per 1000 cubic feet. The pane of glass was found to be covered with a fine dew-like deposit, and its extremely sour taste indicated that it must contain sulphuric acid. This was carefully washed with distilled water into a clean flask. The washings unmistakably held sulphur in suspension. The amount of sulphur deposited on the pane of glass was determined after filtering from the H_2SO_4 solution by oxidizing with nitric acid, precipitating and weighing as $BaSO_4$. From this the amount of sulphur deposited on the glass plate was found to be 0.0014 gm. Since the surface of both

Digitized by Google

sides of the glass pane was 168 sq. in., and the surface of the ceiling and floor 14,504 sq. in., the amount of sulphur deposited on the ceiling and floor would be 0.1208 gm. Assuming that it would be deposited on the walls at the same rate, which may not be entirely the case, there would be deposited on the walls, ceiling and floor 0.3817 gm. or 5.88 grains of sulphur. This amount, though not large, is sufficient to account for the slightly dingy appearance of a room immediately after fumigation, and in part also for the cloud of smoke that arises from burning sulphur. The sulphuric acid in the filtrate as above obtained was precipitated as $BaSO_4$ after the addition of HCl and the $BaSO_4$ filtered and weighed; the H_2SO_4 calculated therefrom was 0.0848 gm. The amount deposited on the ceiling and floor, as calculated from this amount deposited on the pane of glass, is 7.3210 gms., and assuming as above that it would be deposited at the same rate on the walls of the room there would have been formed 15.2 gms., or about 234 grains of sulphuric acid.

Experiment No. 5, Room B.

It being sometimes the practice to place the pot of sulphur on dry ashes instead of in water, the question now arises as to whether by so doing there is the same amount of sulphur burned, and also whether the same amount and relative proportion of sulphuric acid and sulphur are set free as found in the preceding experiment. In order to ascertain these points the following experiment was arranged.

The large tin pan heretofore used was nearly filled with ashes and placed near the middle of the room; on the ashes was placed an iron kettle with 8 lbs. of sulphur. An ordinary pane of glass, 9 by 12 in., was thoroughly cleaned and horizontally supported about 1½ ft. from the floor with a clean glass support. On the wall was also a maximum and minimum thermometer showing a temperature at the beginning of the experiment of 80° F. The sulphur was ignited with burning alcohol and the room thoroughly closed. On opening the room the following day, all smoke had subsided, but sulphur fumes were so strong that it could not be immediately entered. By weighing the pot of remaining sulphur it was found that 2 lbs. 7 oz. had been consumed, or at the rate of 6½ lbs. per 1000 cubic feet, which, as will be noticed, is ⅝ lb. per 1000 cubic feet more than was burned when the kettle was placed in water. Of course this is due to the fact that the water takes some heat from the kettle and its contents and therby reduces its temperature. The thermometer on the wall showed a minimum temperature of 73° F. and a maximum temperature of 113° F. On the glass plate was the same dew-like deposit as before, but showing the presence of sulphur much more distinctly. The deposit was carefully removed with distilled water to a glass receptacle, the sulphur filtered therefrom, oxidized with nitric acid, and precipitated with barium chloride. By weighing the precipitate of $BaSO_4$ and calculating the sulphur, it was found that 0.0228 gramme of sulphur had been deposited on the glass plate. Calculating from this the amount deposited on the ceiling and floor would be 1.5301 grammes. If deposited on the walls at the same rate the entire amount formed in the room would be 4.8352 grammes (74.5 grains). The sulphuric acid in the filtrate from the sulphur thus obtained was precipitated and weighed as $BaSO_4$, from which it was ascertained that 0.1209 gramme H_2SO_4 had been deposited on the plate, or 8.1145 grammes on the ceiling and floor. Calculating as before the total amount deposited in the room would be 25.6397 grammes, or 394.85 grains.

A CASE OF HODGKIN'S DISEASE; WITH AUTOPSY.[1]

BY J. B. MARVIN, M.D.,

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE, AND CLINICAL MEDICINE, KENTUCKY SCHOOL OF MEDICINE.

FOUNTAIN D., colored, aged 35 years, laborer in a tobacco factory, was admitted into my ward at the City Hospital March 3, 1885. He complained of a constant cough, profuse diarrhœa, and great weakness. He laid most stress on his excessive weakness, assigning this as the reason for ceasing work and seeking admission to the hospital.

On examination, the cervical glands on both sides and post-cervical glands were found enormously enlarged, hard, and painless. The neck was stiff, the head rotated with difficulty. The largest mass of glands was on the back of the neck, they elevated the occiput, depressed the chin, and rotated the head to the left, giving the patient a peculiar carriage and expression. The glands in the axillæ and groins were also enlarged, but to a much less degree than those of the neck, hard and painless. There was pain over the abdomen, but no glandular enlargement could be detected. The cough was due to bronchitis. The pulse was quick, feeble, and compressible. Anæmia was marked; the mucous surfaces of the lips, tongue, and conjunctivæ were very pale. Emaciation was excessive, especially of the trunk muscles.

The patient states that about two years ago he had a sore on the penis, followed by eruptions on the skin and sore throat. One year ago he was admitted into the hospital with some secondary manifestations, pains in legs and shoulders, stiff neck, and some enlargement of the glands on the back of the neck. Several months after this the glands about the neck began to enlarge, and he began to lose flesh and strength. None of the glands have ever suppurated. No scars are visible. His blood is pale and watery; examined under the microscope, the red corpuscles were pale, many crenated, and diminished in number; the white corpuscles were increased fourfold. The spleen was not enlarged. The case was diagnosed Hodgkin's Disease, or Pseudo-leukæmia.

Progress of the Disease.—The diarrhœa yielded to treatment; though constantly manifesting a tendency to recur. Cough proved very troublesome, was attended with dyspnœa, especially at night and on exertion. There was a slight, irregular fever. No changes of importance for two weeks, when patient complained of great pain and stiffness in right arm and hand, and right leg; this gradually developed

[1] Read before the Medico-Chirurgical Society.

Digitized by Google

into partial motor paralysis of these members, more marked in arm than leg. Fever increased, with evening exacerbation, very noisy and wakeful at night, appetite fair, and, with assistance, is able to be out of bed and move around the ward. Weakness increased, paralysis more marked, though not complete, no face or eye symptoms. Mind clear, except at night, when a tendency to noisy delirium was manifested. He was now so weak as to be confined to bed, fever continuous, pulse and respiration greatly increased in frequency. Marked pigmentation was now noticed on dorsal surfaces of hands and forearms, forehead, and various portions of the body, the black discoloration contrasting strongly with the dusky-gray, anæmic appearance of the rest of the body.

A few days before death a large bedsore developed over the sacrum; also, a severe stomatitis.

The patient died on April 11th, five and one-half weeks after ceasing work, and three weeks after the appearance of paralysis. He never complained of headache or photophobia. Great weakness and pains in arm and leg alone seemed to distress him. His morning temperature was seldom over 102° F., occasionally it would fall to normal, only to rise in the evening. The evening temperature frequently went to 104° F. The highest temperature occurred ten days prior to death, when it reached 105.2° F., with a pulse of 148, and respiration 48.

In addition to the usual tonic treatment, the patient received increasingly large doses of iodide of potash, hoping that possibly it might do good, as syphilis seemed to be the cause of the disease.

Eighteen hours after death, I made the autopsy. The cervical and post-cervical glands were removed; they were firm, lobulated, reddish-gray in color, in places there was evidence of periadenitis.

On opening the thorax, the mediastinal, cardiac, and bronchial glands were greatly enlarged, very firm, yellowish-white in color. The pressure of the glands probably caused the bronchitis and dyspnœa.

The lungs were healthy, except the base of the right lung, in which was a firm white nodule about the size of a marble. The pericardium contained four ounces of clear serum; the heart was pale and flabby. The liver contained numerous small white nodules. The spleen weighed nine ounces, and contained several soft, white nodules about the size of a pea. The kidneys were not affected. The mesenteric glands were greatly enlarged, many of them being very soft, and on section, revealed thick, creamy matter. The retroperitoneal glands were also greatly enlarged, extending to the pelvis. The suprarenal capsules were healthy. The great size of the retroperitoneal glands causing pressure on the solar plexus probably caused the pigmentation of the skin. The inguinal and axillary glands were not involved to the same extent as the glands in the other regions mentioned.

On removing the calvarium, evidences of slight meningitis were discovered. The brain, on section, appeared pale and bloodless; otherwise it was healthy.

LOUISVILLE, KY.

MEDICAL PROGRESS.

CHRONIC ALCOHOLISM.—Messrs. Dujardin-Beaumetz and Audigé have communicated to the Institute the result of their researches on chronic alcoholism. From June, 1879, to July, 1883, eighteen pigs were experimented upon, each of them with a different sort of alcohol, such as ethylic and methylic alcohol, alcohol prepared from corn, beet-root, and potatoes (pure and impure), absinthe, and tincture of absinthium. These were given daily with the food, in the dose of one to one and a half grammes of alcohol, two grammes of absinthe, and two centigrammes of the tinctura absinthii for one kilogramme of the weight of the body. The symptoms of intoxication by alcohol were sleepiness and prostration, vomiting of bile and glairy mucus, diarrhœa, and sometimes intestinal hemorrhage, dyspnœa, tremor and incomplete paralysis of the hind legs. Some animals which were killed or died during the experiment were examined by Prof. Cornil. He found congestion of the digestive tube, sometimes causing hemorrhage, congestion and inflammation of the liver, but without cirrhosis, congestion of the lungs, and finally, atheroma of the large bloodvessels, especially the aorta. The animals were not emaciated, but presented numerous extravasations of blood into the subcutaneous and muscular tissues. Impure alcohol had a much more rapid and deleterious influence than rectified alcohol. The symptoms caused by absinthe and tinctura absinthii were excitement, and spasmodic contractions of the muscles and cutaneous hyperæsthesia, but true epilepsy was never noticed.—*British Medical Journal*, August 22, 1885.

REMEDIAL EFFECT OF SUBNITRATE OF BISMUTH IN FETID PERSPIRATION OF THE FEET.—VIEUSSE, in *Le Moniteur Thérapeutique*, June, 1885, recommends the subnitrate of bismuth in the treatment of fetid perspiration of the feet, and cites the following conditions in which the remedy is successfully applied:

1. Profuse perspiration of the feet, under whatever form presented, whether manifested in a simple hypersecretion of sweat, or accompanied by pain, or manifested in condition of abundant and fetid transpiration, is easily cured by the application with slight friction of subnitrate of bismuth upon the diseased parts.

2. In opposition to the opinion generally embraced, according to which the suppression of exaggerated perspiration may produce numerous accidents of metastasis, observation shows that the cure of this affection has not been followed by unfavorable results, and that if these are observed they should be attributed to other methods of treatment hitherto employed.

3. In the cure of this disease, subnitrate of bismuth appears to exercise a purely local action, rendering the superficial cuticular structures firmer, and more resistant.

The remedy, perhaps, exerts an action also upon the sudoriparous glands and sebaceous follicles, changing the quality and quantity of their products, and possibly, as a result of the changes produced in the part with which it comes in relation, modifies even profoundly the capillary circulation.

Digitized by Google

4. In certain cases the remedy suppresses only temporarily the profuse perspiration of the feet, but causes the fetid odor, as well as the pain, which is the consequence of the exaggerated secretion, to disappear permanently.—*Rivista Internazionale di Medicina e Chirurgia*, May and June, 1885.

ON THE SIGNIFICANCE OF OSSEOUS LESIONS IN THE DIAGNOSIS AND TREATMENT OF INHERITED SYPHILIS.—A paper on this subject, by DR. R. LOMER, of Berlin, appears in the *Zeitschrift für Geburtshülfe und Gynäkologie* (Band X. Heft 2). It refers to the disease of the bones described by Wegner. Dr. Lomer holds that the presence of these changes in a well-marked form is proof of syphilis; and, applying this test, comes to the conclusion that the large majority of cases of premature labor are due to this disease. General practitioners, in Dr. Lomer's opinion, know very little about these bone lesions. They are to be demonstrated by exposing the femur and making a longitudinal section of it. In a healthy bone the junction of cartilage and bone is a simple line, either straight or undulating, but sharp and well-defined. In a syphilitic bone it is a broad layer, from which irregular processes project into the cartilage. The epiphysis is either quite loosened, or there are deep fissures in the bone below the line of ossification. In some cases these changes can be easily seen with the naked eye, but in others they may be so slight as to need microscopical examination of carefully prepared sections. Although this disease indicates syphilis, yet a normal condition of the bone is not proof of the absence of syphilis. Dr. Lomer puts before his readers the following generalizations, based on the examination of forty-three fœtuses which had died in utero. When the bone disease is well-marked, the liver and spleen are abnormally large. It makes no difference in the degree of the changes present, whether the syphilis is derived from one or both parents, whether in the parent the disease is one year old or ten, whether secondary symptoms have persisted or not, whether the parent has been treated or not, or whether the child be large or small. Syphilitic fœtuses differ in appearance from non-syphilitic. The latter are brown and mummified, the former flesh-colored and more œdematous. In the non-syphilitic the mother can commonly assign a date for the infant's death, and the weight of the fœtus corresponds to the period indicated by her statement. This is not the case with the syphilitic; and in them the placenta is commonly unusually heavy in proportion to the weight of the fœtus.—*Medical Times* (London), August 22, 1885.

TREATMENT OF PNEUMONIA BY LARGE DOSES OF DIGITALIS.—DR. CHRISTE BUICLI, in reviewing a clinical study of the effects of large doses of digitalis in the treatment of pneumonia, made by M. PETRESCU, in the military hospital of Bucharest, gives a table of eight cases treated by the latter—all successfully—and appends the conclusions reached by the author concerning the efficacy of the drug in this disease. Dr. Petrescu, in a review of 350 cases treated by this method, shows that the duration of the disease was shortened, and in every case the intensity of the fever was progressively diminished, while the tolerance of enormous doses of digitalis was also attained. His conclusions are:

1. That digitalis in pneumonia produces a certain and immediate antiphlogistic effect when administered in therapeutic doses.

2. The therapeutic dose in this disease is from 60 to 90 grains of the leaves, during twenty-four hours, for a limited number of days.

3. The treatment of pneumonia by digitalis is up to the present time the only method which has reduced to a minimum the mortality consequent thereto.—*Le Progrès Médicale*, August 15, 1885.

REMOVING MICROBES FROM WATER.—PROFESSOR FRANKLAND has, we read in the *Journal of the Society of Arts*, recently made a series of experiments on the relative efficiency of filtration, agitation with solid particles, and precipitation, as a means of removing microorganisms from water. His method was to determine the number of organisms present in a given volume of the water, before and after filtration. The filtering materials were green sand, silver sand, powdered glass, brickdust, coke, animal charcoal, and spongy iron. These materials were all used in the same state of division, being made to pass through a sieve of forty meshes to the inch. Columns six inches in height were used. It was found that only green sand, coke, animal charcoal, and spongy iron wholly removed the microorganisms from the water filtered through them, and that this power was lost in every case, after the filters had been in operation a month. With the exception of the animal charcoal, however, all these substances, even after being in operation for a month, continued to remove a very considerable proportion of the organisms present in the unfiltered water; and in this respect coke and spongy iron occupied the first place. Water containing microörganisms was also agitated with various substances in the same state of division as above mentioned, and after subsidence of the suspended particles, the number of organisms remaining was determined. A gramme of substance was in general agitated with 50 cubic centimetres of water for a period of about 15 minutes. It was found that a great reduction in the number of organisms could be produced in this way; and the complete removal of all organisms by agitation with coke is especially to be remarked. Precipitation by "Clark's process" also showed that it affords a means of greatly reducing the number of these organisms in water. Dr. Frankland concludes from his experiments, that, although the production in large quantities of sterilized potable water is a matter of great difficulty, involving the continual renewal of filtering materials, there are numerous and simple methods of treatment which secure a large reduction in the number of organisms present in water.—*British Medical Journal*, August 15, 1885.

PREGNANCY AFTER DOUBLE OVARIOTOMY.—SCHATZ, in the *Centralblatt für Gynäkologie*, records the case of a woman who became pregnant after the operation of double ovariotomy. The woman for a long time had suffered abdominal pain, and the operation was performed February 20, 1880. The left ovary was found to be in a condition of fibroid degeneration, and was completely removed together with the external portion of the corresponding Fallopian tube. The right ovary also showed signs of cystoid degeneration, and was re-

Digitized by Google

moved, with the exception of a small band—at the most only one-twelfth of an inch wide. The right Fallopian tube remained intact. Cure resulted without incident, save the occurrence of an abscess formed in the path of one of the sutures. A month after operation violent pain in the hypogastrium and thigh was experienced, in lieu of the menses; but finally, on June 20, menstruation occurred and continued up to the time of the patient's marriage, April 23, 1884. The symptoms of pregnancy were well marked at the beginning of September, and accouchement at term occurred May 12, 1885, after thirty-six hours' labor.

LICENSES TO PRACTISE MEDICINE IN JAPAN.—The *Supplement to the Transactions of the Sei-i-Kwai* for May, 1885, contains a copy of the regulations for the examination of candidates for licenses to practise medicine. The Minister for Home Affairs is to hold examinations twice yearly, six months' notice of the time and place being given. At the time of the examination, he is to appoint an examining committee selected from hospital physicians, or from physicians and chemists of known medical knowledge; a dentist may also be appointed in the case of examinations for licenses in dentistry. A manager is to be appointed to superintend the examinations. The examinations for the license to practise medicine are divided into two parts, unless the candidate can take the whole examination at once. For the license in dentistry, there is but one examination; the subjects being Dental Anatomy and Physiology, Dental Pathology and Practice, Dental Medicine, Dental Mechanics, and a practical examination. The subjects of the two examinations for the license to practise medicine are: first, Physics, Chemistry, Anatomy, and Physiology; second, Theory and Practice of Surgery and of Medicine, Materia Medica, Ophthalmology, Obstetrics, and Clinical Observation. A course of study of not less than a year and a half's duration must be pursued before the first examination, and an additional course of like duration before the candidate can be admitted to the final examination. The answers to the questions are to be given in writing; but, under certain circumstances, they may be given orally. Candidates who pass are to receive a certificate, attested by the manager and the examining committee. Rejected candidates are not admitted until after a lapse of at least six months. The fees are, for the primary examination, three *yen* (about 11 shillings); for the final examination, five *yen;* and for the examination for license in dentistry, five *yen*. The fees are not to be refunded in case of inability to attend or complete the examination. —*The British Medical Journal*, August 29, 1885.

TUBERCULAR INFECTION THROUGH SEXUAL INTERCOURSE.—FERNET, at a meeting of the Société Médicale des Hôpitaux, January 7, 1885, in a paper upon the possibility of the occurrence of tubercular infection through sexual intercourse, summarized his views as follows:

1. Primitive genital tuberculosis may probably be caused by direct contagion in sexual intercourse.

2. The indolent blenorrhagic discharges sometimes observed in certain men, subsequent to sexual relations, especially when not consecutive upon true blenorrhagia, should be regarded with suspicion. Some of the discharges appear to be of a tubercular nature. The same may be said of certain forms of leucorrhœa in woman. A search for the bacillus tuberculosis must decide the nature of these discharges.

3. Sexual relations with subjects affected with genital tuberculosis expose to direct contagion, and present a risk which it is wise to avoid.

4. A principal danger of genital tuberculosis is the risk of general secondary infection. The cure of such genital tuberculosis should be attempted by all known remedial agencies, and even by surgical interference.—*Revue des Sciences Médicales*, July, 1885.

THE CUMULATIVE ACTION OF DIGITALIN AND HELLEBORIN.—M. VAN DER HEIDE, in endeavoring to confirm the cumulative action of digitalin and helleborin by experiments upon animals, has reached the following conclusions, some of which favor, while others oppose the reality of such action in these drugs. He found

1. That with very minute doses (one-eighteenth of a grain) administered in succession at intervals of considerable length (one day), he has succeeded in killing dogs of large size.

2. A dose not fatal under ordinary circumstances frequently suffices to kill animals already under the influence of small doses for a considerable period.

3. The slowing of the pulse persists a long time after the administration of the final dose, as has already been noted by Sandras (1883) concerning digitalis.

4. The maximum effect upon the heart is obtained subsequent to the administration of the final dose when several equal doses are administered at greater or less intervals.

5. Toxic effects which a given dose is unable to produce are frequently observed when such dose is repeated a sufficient number of times, and at sufficiently great intervals.

On the other hand, Van der Heide has observed

1. That toxic symptoms disappear under the prolonged administration of digitalin or helleborin in uniform doses.

2. That doses which at first strongly influenced the frequency of the heart, lost much of their effect according to the length of time during which the experiments were prolonged.—*Gazette Médicale de Paris*, August 22, 1885.

HYSTERIA IN MALES.—At a recent meeting of the balneological section of the Gesellschaft für Heilkunde, Berlin, DR. JOSEPH, of Landeck, read a paper upon this subject, describing two cases. An apprentice in a house of business, "of good family," had an attack of acute rheumatism when eighteen years of age. Convalescence was protracted, and followed by great distention of the stomach, hiccough, and general clonic spasms of the voluntary muscles, forcing the trunk suddenly into all manners of attitudes, and causing obstruction to deglutition, etc. After treatment at a hydropathic establishment, all these symptoms disappeared, but were followed by ptosis and right motor hemiplegia, with hyperæsthesia on both sides of the body. The convulsions returned after the paralytic symptoms had abated. Dr. Joseph then examined the patient, who appeared to be robust, muscular, and ruddy complexioned. He stared suspiciously at bystanders, and was very excita-

Digitized by Google

ble. He walked slowly, and with the aid of a stick, dragging the right foot. Percussion of the thorax caused opisthotonos; the six lower dorsal vertebræ were especially sensitive. The appetite had become very good, and globus was frequent. The bowels remained constipated for days or even weeks. No history of sexual abuse of any kind could be traced. After ten weeks of hydropathic treatment, he left Landeck apparently cured. It was found that the patient's grandfather, who had recently died, aged 78, had suffered for fifty years from hysterical fits precisely similar to those observed in young women.

The second case was that of a robust horse-dealer, aged 38, who had a flourishing business in Prussian Poland. He had served for three years in a German cuirassier regiment, and was father of a large family. Four years before consulting Dr. Joseph, he caught cold, and aphonia followed. A little later, clavus was complained of, and then he began to have convulsive attacks, without loss of consciousness, but with loss of power of speech. These attacks were often followed by vomiting. Then, when he applied to Dr. Joseph, he became subject to globus, hoarseness without objective laryngeal symptoms, and great mental irritability. The physician witnessed a fit. The patient, a very tall, strong man, lay stretched out in bed, with clonic convulsions of all his extremities; he was quite conscious, but could not speak. There was constant hyperæsthesia over the interscapular region, the lower cervical and upper dorsal vertebræ, but not in the iliac region. The patient was relieved by hydropathic treatment. There was no family history of hysteria or epilepsy.— *The British Medical Journal*, August 29, 1885.

INFECTIOUS PERITONITIS IN VIRGINS.—DR. SNYERS has described in the *Annales de la Société Med.-Chirurg. de Liège* (*Journal de Méd. et de Chir. Prat.*, 1884), two interesting cases, which seem to show that the virus of erysipelas can cause, in women who have never had intercourse, an acute form of peritonitis, similar to that observed in puerperal cases. A young woman (a virgin), aged 18, was suddenly seized with symptoms of acute peritonitis five weeks after a servant in the house had been taken ill with erysipelas of the face; death ensued in thirty-six hours. Shortly afterwards, the brother of the young woman had an attack of erysipelas on the arm; this did not cause much anxiety at the time; but, a fortnight later, the second sister, aged 20 (also a virgin), was seized with the same symptoms as the first, and died in less than two days. At the *post-mortem* examination, Dr. Firket failed to discover any local cause by which the origin of the inflammation might be explained. The spleen was much swollen, and the blood had the same appearance as in cases of infectious diseases.—*The British Medical Journal*, August 29, 1885.

REMOVAL OF TUMORS OF THE BLADDER.—DR. ANTOINE SABASTIER, at the conclusion of a critical review of the operation for removal of vesical tumors, founded on observations made upon forty-seven cases removed either by hypogastric or perineal section, summarizes his views concerning the condition and the indications for operation as follows:

1. Every tumor of the bladder having almost certainly a fatal prognosis, surgeons should be impressed with the necessity of early operation when the disease exists.

2. When the diagnosis is uncertain, membranous urethrotomy should be performed as an exploratory operation.

3. Small tumors developed over the trigone of the bladder, and of a benign nature, seem best removed, in view of their radical cure, through the perineum by membranous urethrotomy, the median or lateral operation.

4. Large tumors of the bladder, multiple and extended, and situated in the superior vesical hemisphere, and of a malign nature, should be operated on by the hypogastric section.

5. In those cases where radical cure is impossible, incomplete ablation almost always affords considerable relief. Such palliative operations should be preferably done in the suprapubic region and a permanent urinary fistula established.—*Revue de Chirurgie*, August, 1885.

COCAINE IN SEA-SICKNESS.—In a preliminary report on some observations upon "cocainum muriaticum," DR. MANASSEIN, of St. Petersburg, gives an interesting account of the employment of the drug in sea-sickness (*Berl. klin. Wochensch.*, August 31st). He had read of its value in uncontrollable vomiting of pregnancy, and thought it might be useful in sea-sickness. He, therefore, went this summer on a sea voyage in order to test its efficacy. Among his fellow passengers were two, a man and woman, who were especially prone to the malady. He administered to each of them every two or three hours a teaspoonful of the following solution: Muriate of cocaine 0.15, rectified spirits of wine (in sufficient quantity), and distilled water, 150.0, beginning the administration on starting. That it had a prophylactic effect seemed clear, for in spite of very rough weather for a period of forty-eight hours, both the individuals were for the first time in their lives free from sickness, and enjoyed a very good appetite the whole time. To a child six years old, who began to be attacked with sea-sickness on rising in the morning, the treatment was so effectual that it was able to play about during the day in spite of the storm. The child took one teaspoonful in two doses during the first half-hour, and then half a teaspoonful every three hours. Another case was that of a girl, eighteen years of age, who had been sick for twenty-four hours before the drug was given. The case being a severe one, she had a double dose every half-hour, with "truly magical effect;" for after the second dose the patient was able to assume a half-sitting posture, and after the sixth dose she jested and began to complain of hunger. During the rest of the voyage she remained well, although there was much rolling of the vessel. Similar good results attended the use of the drug in three milder cases; and had it not been that his supply ran short Dr. Manassein would have been able to make more extended observations. Still, from the experience of these few cases he thinks it justifiable to infer that in the drug we have a certain and harmless remedy against sea-sickness. In the same communication he mentions that he had found "cocainum muriaticum" of great service in arresting the collapse of two severe cases of simple cholera, and thinks it desirable to try its action in cases of Asiatic cholera.—*Lancet*, September 5, 1885.

SATURDAY, SEPTEMBER 19, 1885.

THE CLINICAL SIGNIFICANCE OF PEPTONURIA.

ONE of the first to avail himself of the accurate method of Hofmeister, for the determination of peptonuria, detailed in a recent issue of THE NEWS, was Maixner. His most important conclusion was that the presence of peptone in the urine points to suppuration and the simultaneous disintegration in the economy of pus corpuscles.

A little later, v. Jaksch published the result of his investigations on peptonuria, based on the study of some hundreds of cases. He confirmed in general Maixner's earlier conclusions, he never once found peptonuria in any of the acute infectious diseases—typhoid, typhus, and intermittent fevers, measles and scarlatina,—and out of three cases of phosphorous poisoning which he studied, it occurred in one. He also found it in scorbutus attended with disintegration of colorless corpuscles, and called it "hæmatogenous" peptonuria. In 1882, Poehl, besides finding peptonuria in the last stages of the inflammatory process, asserted that all albuminous urine of acid reaction contains peptone, which diminishes or entirely disappears when it becomes neutral or alkaline. On the contrary, in acid urine, non-albuminous but peptone holding albumen appears when the reaction becomes neutral or alkaline.

In 1884, Fenomenow, in Russia, published a paper in which, besides confirming Maixner's results, he called attention to the possible origin of peptone from albumen, in which, first confirming the experiments of Eichwald, made as far back as 1864, he showed, also, that such morphological constituents of the urine as pus, blood and epithelium, exerted, to a certain degree, a fermentative action upon albuminous urine of acid reaction, resulting, when they are abundantly present, in the appearance of peptone. Indeed, he asserted that peptone is only found where these cellular elements are abundant. In this way Fenomenow explained the excretion of tube casts, which, firmly seated in the uriniferous tubules, are only cast out when they become peptonized on their external surfaces. In 1884, also, Maixner described what he called the "enterogenous" form of peptonuria occurring in cancer of the stomach and typhoid fever, where the peptone of digestion is absorbed directly into the circulation, and passes thence into the urine.

Quite recently, PACANOWSKI, in the *Zeitschrift für klin. Med.*, 9 Bd. 5 Heft, August, 1885, has published the results of the study of this matter in a large number of cases of disease. He used both tannic and phosphortungstic acid for precipitating the urine, and considers the latter more convenient and the method shorter. To remove albumen, acetate of iron is to be added only as long as abundant flocculi are precipitated, not, as Hofmeister says, until the fluid becomes permanently red, for this seldom occurs, the color remaining brownish or reddish-gray. Further, as to the decomposition of the phosphortungstic precipitate with baryta, there appears at the beginning of the rubbing a green color which should pass over into yellow. Should this not occur after much rubbing, more baryta should be added and the rubbing continued. Only when the precipitate is yellow has complete decomposition taken place. Then after adding a little water and boiling, the entire precipitate falls, and the supernatant fluid remains bright yellow. To this he applied the "biuret" test already described in these pages.

Pacanowski's observations covered 211 cases of disease, and included 810 urine analyses, in 350 of which he used the tannin method of precipitation. In 36 cases of typhoid fever it occurred twenty-five times; in 2 cases of typhus, once; in 2 cases of variola, twice; in 2 of scarlatina, twice; in 4 of intermittent fever, once; in 4 of miliary tuberculosis, twice; in 3 of erysipelas, three times; in 6 of acute rheumatic arthritis, six times; in 2 of chronic arthritis, once; in 25 of pulmonary phthisis, eleven times; in 5 of chronic pneumonia, twice; in 7 of croupous pneumonia, seven times; in 6 of purulent pleurisy, four times; in 2 of embolism after insufficient mitral valve, twice; in 3 of angina of the fauces, once; in 1 of carcinoma of the œsophagus, once; in 3 of carcinoma of the stomach, three times; in 2 of carcinoma of the rectum, twice; in 1 of perityphlitis, once; in 5 of catarrhal jaundice, three times; in 2 of hypertrophic cirrhosis of the liver, once; in 3 of cancer of the liver, three times; in 5 of parametritis, four times; in 2 of cerebral apoplexy, twice; in 1

Digitized by Google

of parotitis, once; in 2 of abscess, once; in 1 of ecchymosis after trauma, once; and in 1 of muscular rheumatism, once. He found it absent in 1 case each, of diphtheritic angina, fibrinous pericarditis, ulcer of the stomach, purulent peritonitis, acute nephritis, gonorrhœal orchitis, hemiplegia, epilepsy, anæmia—probably pernicious, diabetes mellitus, external otitis, ambustura and necrosis; in 2 cases of serous pleurisy, chronic endometritis, myoma of the uterus, chronic leptomeningitis, tabes dorsalis, leukæmia, gonitis fungosa, sarcoma of the neck and superior maxilla; in 3 each of measles, insufficient mitral valve, chronic gastritis, acute enterocolitis, cholelithiasis, and cyst of the ovary; in 4 each of chronic nephritis, and neuralgia; and 5 each in chronic bronchitis, chronic myelitis, and hysteria.

He further divides the cases into acute and chronic, including in acute peptonuria the various forms of inflammatory (suppurative) process of the acute infectious diseases. In the chronic are included carcinoma, pulmonary phthisis, and diseases of the liver.

In the case of typhoid fever, as to which the results of Maixner and v. Jaksch were at variance, Pacanowski, agreeing with Maixner, found peptonuria tolerably frequent, almost constant at the beginning of the period of defervescence, or a few days earlier, and this in the milder, as well as the more serious cases. Indeed the reaction was at times more distinct in the former. So long as continuous fever was present, so long as the typhoid symptoms were strongly expressed, peptonuria could not be demonstrated. Nor was it found in those fatal cases in which there was no suppuration. In one case, however, accompanied by phlegmonous abscess, there was peptonuria, but after incision into the abscess, and removal of the pus, peptonuria disappeared. In cases of relapse, if there was peptonuria in the primary disease, it reappeared in the relapse.

What has been said of the time of appearance of peptonuria and its relation to the febrile process in this disease is true of the other infectious diseases, including miliary tuberculosis.

In explanation of this very interesting condition in typhoid fever, Pacanowski does not accept either of the more recent views of Maixner. That of Gerhardt, that it is due to the action of high temperature upon the albumen conversion of the blood plasma, has long been laid aside. Maixner first, with Schueltzen and Riess, ascribed peptonuria to an insufficient oxidation of the nitrogenous and non-nitrogenous substances which normally result from the splitting up of albumen. As a consequence of this, albumen does not pass over into the usual products, urea, uric acid, etc., but retains a stage of less complete oxidation. Thus it is that we have leucin and tyrosin in the urine in acute yellow atrophy of the liver. This view, entirely theoretical, is not sustained by facts, according to Pacanowski, for in typhoid fever there is not an inhibited, but rather an increased oxidation of the principles of the body.

The more recent view of Maixner, also rejected by Pacanowski, ascribed peptonuria to the abundant exfoliation of epithelium and the presence of albuminous intestinal juices, together with deficient supply of nutritious matter.

The action of the lower organisms upon albumen has also been suggested in explanation, but if this is the case, says Pacanowski, why is not a proportionate degree of peptonuria present in miliary tuberculosis and in fatal uncomplicated typhoid fever?

Pacanowski himself thinks we need not go further than the local phenomena of inflammation which are found in some places, and, in some form, in all the infectious diseases in which peptonuria is present. Preeminently is this the case in typhoid fever, where we have, at first, an inflammation of the entire intestinal tract, including a small-celled infiltrate of the follicles and mucosa. Later we have ulceration of the solitary glands and Peyer's patches, necrosis and separation of slough, followed, in favorable cases, by healing with a smooth cicatrix, and the resorption of the deeper layers of the intestinal infiltrate, as well as that of the mesenteric glands. Thus are furnished the very conditions which Maixner in his first paper showed to be responsible for peptonuria in simple exudative processes

That peptonuria does not occur during the period of ulceration in typhoid fever, but rather at the beginning of the process of healing, is explained by the fact that ordinarily the typhoid ulcer has, after separation of the slough, a clean, smooth bottom in which are wanting the proper conditions of absorption, while, in addition to this the products of the sloughing process are promptly carried away by the diarrhœa. This agrees with the fact long known, that on exposed surfaces the absorption of the peptone originating from the disintegrating pus cells does not freely take place as long as the products of cell disintegration can pass easily away. But in closed cavities, as in parametritis and articular rheumatism, and in parenchymatous organs, we have conditions favorable to the absorption of the exudate.

At the beginning of the healing process in typhoid fever, we have the conditions favorable to peptonuria. The mucous membrane of the ileum, richly infiltrated with cells, the muscular and subserous layer as well as the cell-infiltrated gland apparatus, are returning rapidly to their normal state, and the cellular elements of the infiltrate as rapidly undergo disintegration, furnishing the peptone for absorption. Peptonuria in milder cases of typhoid is explained by the absorption of the cellular infiltrate which is present even where there is no ulceration, and, in other acute infectious diseases, where there is abund-

ant cell infiltration, as in Pacanowski's two cases of scarlatina, where there were angina and swelling of the cervical glands, the same explanation holds; so, too, in that of smallpox, where the pustules dried on the surface; in intermittent fever, where there was reduction in the size of the spleen by the action of quinine; in all these there was peptonuria. On the other hand, in the three cases of measles where there were no such conditions, there was no peptonuria. Furthermore, peptonuria occurred in cases of non-inflammatory hemorrhagic exudate, in which it may be ascribed to the absorption of effused blood. Such were two cases of cerebral hemorrhage, and one of contusion of the thigh.

The study of chronic peptonuria, in phthisis, pneumonia, and cancer, would seem to show that, except in cases of the last, it is everywhere due to the same cause—the disintegration and absorption of cellular elements.

In phthisis it was more particularly in the earlier stages, where the dulness of the apex was slight, and cavities were still absent. Where there was extensive loss of lung tissue, and even in simultaneous ulceration, there was no peptonuria, and it was altogether independent of high temperature.

In cancer of the gastro-intestinal tract, where peptonuria is common, the primary explanation of Maixner, that it is due to the absorption, by the ulcerated surfaces, of the peptone of digestion, as well as that produced by the disintegration of the new formation itself, still holds good; but in cancer of the œsophagus, rectum, and uterus we must have recourse to the disintegration of the new-formed cellular tissue as the sole source. Such was the case in a decided degree in one case of cancer of the uterus in which there was peptonuria, while there was none in the second, where there was no such disintegration.
